TO OUR READERS.

It may be well to devote a few brief sentences to recall to your memory one or two of the events of the past six months; for wisdom is the application of knowledge extracted from the past and applied to the future.

In gardening great events rarely occur, but there are a continued series of small events in its practice which combine, and become of marked importance. Such a combination has resulted in the prevalence of conservatories. A majority of the houses now springing up for the middle thousands in our metropolitan districts have each a conservatory. In these conservatories we recognise an increased source of pleasure, health, home enjoyment, and love of the beautiful. The Chancellor of the Exchequer had no such result in view when he proposed the repeal of the duty on glass, and we have the high satisfaction of knowing that our pages helped to the knowledge which created a demand for their erection.

When we announced that cocoa-nut fibre dust is excellent for potted Ferns and some other plants, we little thought that we were introducing such an additional source of fertility to the gardener; that we should be the cause of sweeping away the mountains of this refuse which the manufacturers gave gladly to any who would fetch it away, but which they now can afford to advertise, sell at a good price, and cannot manufacture fast enough. It has become an ingredient in the composts of many large gardening establishments; and from being timidly used in flower-pots, is now employed in bushels to banks of Rhododendrons, Strawberry-beds, and other extensive plantations.

Within the six months embraced by this volume the memorial to the Prince President of the Royal Horticultural Society, has been erected, and the representatives of the people have refused to purchase its neighbouring International Exhibition building. Had that wise Prince survived he would have applauded that rejection, for he never sanctioned attempts to adapt incompatibles; and we now hope to see a building rise from the foundations of the one condemned that will be a worthy and suitable national museum, and that will increase the attractions of the national Horticultural Society's Garden.

It is in no spirit of self-laudation, or from any prompting of self-interest, that we assume to have had an influence in promoting those occurrences, but it is paying a due tribute to those able men who contribute to our pages, and whose skill and high character gain for them an entrance into most places where gardening is cherished. Illness has withdrawn from us one of the most able of those men; but more than one of equal skill have been added to our staff, and we have no fear that our pages will not continue to be welcome, as we are told by a Lancashire clergyman they have been hitherto "to my parsonage, our squire's drawing-room, his gardener's parlour, and our village reading-room."

INDEX.

- ABRUS PRECATORIUS** sowing, 173
Acacia squamata, 417
Acacias, propagating, 301
Accrington Poultry Show, 268
Achimenes—*Carminata elegans*, 137; dying, 214
Achras sapota sowing, 173
Adiantum macrophyllum culture, 325
Advertisers, caution to, 352
Adrides maculosum var. Schröderi, 245
Afghanistan, plants and gardening in, 478
Ageratum, variegated, 404
Agricultural Hall Poultry Show, 386, 405
Air, admitting near smoky towns, 455
Albert's, Prince, Memorial inauguration, 430
Alcove-aviaries and bowers, 10
Algae, new mode of preserving, 162
Alocasia—zebrina, 300; **Lowii**, 343
Aloe too high for house, 301
Alyssum—variegatum edging, 177; *saxatile*, 474; *compactum*, 414
Amaranthus melancholicus, 333
Amaryllis—seedlings blooming, 177; and its varieties, 371; culture, 452
American Gooseberry, 300
Ammonia fixing beneficial, 434
Anagallis, sowing, 158
Anemone-bed, management, 481
Anemones not flowering, 267
Anguloa Ruckeri, 419
Annuals—list of, 275, 283, 301; select lists, 241; and culture, 321, 323; list of hardy, 325; sowing, 333, 403; twenty select, 434; merits and defects of, 473
Ants, to banish, 385
Aphelandra Leopoldii culture, 441
Apis Persice, 209
Apiarian notes, Morryshire, 180
Apiary, B. & W.'s, 269
Apis dorsata, 320
Apoplexy in fowls, 124
Apothème, does it enter plants? 152, 186
Apple—trees, mossy and decaying, 56; summer-pruning dwarf pyramid, 56; of *Amassia*, 155; seedlings from Newtown Pippin, 267; transplanted o'd, 267; tree shoots diseased, 283; buds deformed, 283; trees, lifting frequently, 413
Apricot—management, 163; **Canino Grosso**, 293; trees in bloom, treatment, 113; trees, management of, 200
Apricots—in orchard-houses, 24, 276; failing in orchard-house, 56; in bloom, treatment, 154; treatment of in bloom, 186; and orchard-houses, 220; on *Cotswold Hills*, 221; in greenhouse, 234; far north, 244; *Afghan*, 478
Aquatics, hardy, 56
Arancaria, moving, 385
Arctotis reptans, 109
Artichoke, protecting, 11
Artichokes—not quite hardy, 70; Globe, spring management of, 248
Asparagus—forcing, 34; beds, insects in, 193; culture, 366; beds, seaweed for, 385
Aspidistra punctata albo-maculata, 419
Asters, 146
Atriplex hortensis rubra as an edging, 103
Auricula—Show, National, 9; in 1863, 323; *Princess of Wales*, 419
Auriculas—the *Alford*, 324; where to be obtained, 324; house for, 324; shifting, 441
Australia, garden produce in, 401
Australian seeds, 268
Aviary—Ivy in, 144; window, 270
Azalea—leaves falling, 13; *Surprise*, 419
Azaleas—after flowering, 250, 441; dying after flowering, 282; cutting-down old, 333; after cutting back, 333, 385; potting, 392
BALDROOT, YOUNG OF, SEEN, 361
Balsams, sowing, 158
Bantams—yellow-legged Game, 19; in a garden, 20; Black, disqualified at *Darlington*, 37; legs of Game, 38, 126; with willow legs, 64; Black, combs, 198; *diarrhea* in, 270; laying soft eggs, 354; Black, at *Bradford*, 463
Barbadoes, seeds from, 173
Barometer, water, 114
Bath and West of England Poultry Show, 215, 251, 284, 351, 442
Bay trees injured by frost, 267
Bedding-out, 301; how to manage, 366, 368; at *Putteridgebury*, 383
Bedding plants, 300
Bee-feeders, 19; season in *Surrey*, 40; keeping, *Staffordshire*, 144; season, commencement of, 160; keeping, 162; protector house, 179; season in *Renfrewshire*, 196; keepers, meeting of *German*, 197, 285; houses, 215, 354; books, *British*, 387
Bees—in-door apiary, runaway swarms, 41; bottle-feeders, 42; evening thoughts on, 42; cause of deserting hives, 61; cure for stinging of, 63; deserting hive, feeding imprisoned, profitless, 84; in buildings, 85; in churches, &c., 86; early pollen-gathering, bottle-feeder and moth-trap, 106; excluding queens and drones, 106; first spring flight, 125; profitless, 126; bottle-feeding, 126, 216; early pollen gathering, 126; in winter, 144; fertile workers, 160; need they be profitless? 161; purchasing, 162; in buildings, 180, 216; death of a whole hive, 180; superposing, 196; drones in *March*, 197; covering hives, 198; ventilation of hives, 198; wintering in glass hives, 198; best aspect for, 216; in *N. Staffordshire*, 216; *Ligurian*, in *Australia*, 235; at *Bath*, 235; fertile queens, distance they fly, 236, 286, 335, 464; in *N. of Scotland*, 236; exotic; size of cells, 252; spring pasturage for, 270; in *New Forest*, 270; diving, 270; feeding, 286; *South American*, 280; artificial swarms, 285; feeding, mortality of, 3; 3; uniting, do *Ligurian* suck red clover? food for, 304; virgin queens drone-producers, burying combs, 320; combs fallen, 320; swarm in *April*, 334; B. & W.'s apiary, 335; feeding, hive deserted, fertile queens, 335; aspect, 336; feeding, 336; protecting glasses, uniting stocks, choosing hives, 336; transferring their allegiance, 332; aspect for, queens destroyed by workers, *Ligurians* and clover, drone-breeders, 333, 368; use of pollen, diligence of, exporting eggs, purifying honey, promoting early swarms, 370; food escaping from bottles, 387; dark *Ligurian* drones, 388; drones of a drone-breeding queen, 406; law relative to strayed swarms, 406; swarming difficulties, 425; dark *Ligurian* drones, 426; "B. & W.'s" apiary; taking a side-comb; feeding, 444; exhibition of, 446; dying; *Ligurians* in *Australia*; season in *Durham*, 446; season in *East Lothian*, 463; age of queens, death of queens, season in *Staffordshire*, 464; young expelled; transporting stocks; queenless swarm, driving, distance between bars, variety of, 483; dying in *June*, variations, simultaneous attacks on drones, not entering a super, 484
Beetroot edging, 35
Begonia—leaf cuttings, 100; *Griffithi*, leaves rooting in water, 475
Begonias—suffering from cold, 9; culture and list, 110
Belladonna Lily, planting, 56
Belt of trees on clay soil, 81
Beverley Poultry Show, 423
Birds—useful in a garden, 154; to prevent their injuring *Gooseberry*-buds, 187; of prey, a prayer for, 334; a plea for, 457
Birmingham poultry sale, 143
Birmingham Rose Show, 340, 361
Bixa orellana sowing, 173
Blower dropping, 311
Boiler—Riddell's, 122; a good one asked for, 292; a good, 330, 359, 364
Boilers, 55; for garden structures, 32; requisites in, 257; bursting, 318
Borders, fruit, cropped, 228
Bossiaea culture, 30
Botanic (Roya') Society's Show, 240, 280, 315, 357, 409, 468
Bottom heat, 193
Bougainvillea speciosa, 351
Bouquet, *Princess of Wales's* *Bridal*, 202
Bower-birds, 162
Box-edgings, trimming, 282
Brahma Pootra—remonstrance of, 194; egg-bound, 406
Breast, crooked, in fowls for exhibition, 386
Broccoli—preserving cut, 12; culture, 94
Brugmansia culture, 122
Buckwheat for poultry, 20
Budrigas, managing, 106
Bulbs—management of *Cape*, 141; *Cape*, cause of their not flowering, 193; *Cape*, 228; in pots, 250; after flowering, management, 313
Bull's Mr., plant establishment, 376
Bushel, its size formerly, 167
Butter, ill-flavoured, 388
CAFE AU LAIT, 354
Calabar Bean, 341
Caladimorphia, 123
Calanthe—*vestita* culture, 90; *Veitchii hybrida*, 293
Calceolaria—cuttings, 177, 249; colours of, 250; tetragona, 362; amplexicaulis, match bed, 404
Calceolarias—leaves black, 5; culture, 6; new, 108; deformed, 132; and *Geraniums* for chain-border, 300; wind-injured, 386
Callicarpa americana, 6
Camellia—flowers deformed, 35; flowers imperfect, 56; leaves spotted, 81, 267; buds dropping, 299; *Duchesse de Berri*, 343; leaves partly yellow, 403; soil, 481
Camellias—heating pit for, 158; after flowering, 250; not flowering, 333; large, 360
Campylobotrys refulgens culture, 441
Canaries—breeding, 252; dying, 388
Canary—ceasing to sing, 354; not mating, 426; cross with *Yellow-hammer*, 464
Canna indica sowing, 173
Carnation Samuel Moreton, 229
Carton, *Duke of Leinster's*, 115, 130
Carrot soup, 304
Catalpa not flowering, 385
Caterpillars, the best way to destroy, 447, 461
Cauliflowers, preserving cut, 12
Cedar of Lebanon, pruning, 267
Celery culture, 6, 46, 55, 115, 121, 348
Cement for putty, 14
Centaurea, candidissima, 122; propagating, 35; *ragusina*, 103; dying off, 193
Cerastium tomentosum—culture, 177; management, 423
Cereus pterogonus, 127
Ceylon, importing plants from, 301
Chair, *Ha-sard's* portable, 227
Chamærops Fortunei, its hardiness, 453
Cherries, black fly on, 404
Cherry—*Belle Agathe*, 230; and *Plum aphid*, destroying, 422
Chickens—death of, 144; management of early, 144; real spring, 234, 252; how obtained gratis in *America*, 235; with colds, 252; remaining with hen, 320; dying suddenly, 320; out of doors, 365; before weaning, food for, 387
Chinese fruit-gardening, 361
Chinese Primrose, *Fern-leaved*, 419
Chorozema—cordata, specimen, 170, genus, culture of, 259
Chrysanthemum—*Striped Japanese*, 293; varieties of, 293; history and cultivation, 237; varieties for pot culture, 238; to seed, 238; insect enemies, 239
Chrysanthemums, 25; *Her Majesty* and *Lord Palmerston*, 76; not blooming, 81; *Pompon*—*Fairest of the Fair*, *Mary Lind*, and *Julia Englebach*, 137; blooming time, 141; list of hardy large, 267
Cinechoma officinalis, 137
Cinechonas, list of and culture, 434
Cineraria—leaves injured, 193, 228; 267; cordata, 293; *maritima* seedlings, 333
Cinerarias—cutting-down and sowing, 333
Cissus discolor culture, 123
Clay—burning, 250; soils, improving, 65, 441
Clematis, to propagate, 193
Cianthus Dampieri sowing, 214, 250
Climate of England, has it changed? 413, 456
Climbing birds, 352
Club root, 476
Cobaea scandens flowers altered, 403
Cock drooping, 252
Cockerels fighting, 162
Cochin-China—with diseased liver, 354; feet inverted, 354; legs paralysed, 370; *diarrhea* in, 370; chickens' management, 426
Cocoa-nut-fibre dust—for propagating, 47, 56; over hot-water pipes, 70; in compost, 103; as a manure, 141; experiments with, 205; quantity needed, 250
Coccoloba platyclada, 419
Codonopsis cordata, 293
Colognye lagenaria, 293
Coke as fuel, 233
Cold, fowls affected with, 162
Coleus plants damping-off, 267
Colours—harmony of, 153; arrangement of, 200
Columbarian Society, National, 105

- Conifers in Ireland, 154
 Conservatory—plants for back, 14; pillars, plants for, 141; water for, 386; aspect for, 438
 Conservatories, construction of, 171
 Coral, 20
 Cork Poultry Show, 39, 57
 Cornwall, crops in, 329
Corysanthes limbatia, 76
Cotoneaster microphylla—leafless, 158; its uses, 458
 Cottage gardens, judging, 408
 Cotton seed-cake as a manure, 114
 Cows, furze for, 63
Crassula coccinea not blooming, 169
 Creeper for rustic basket, 441
 Crève Cœur fowls laying, 252
 Crève Cœur not laying, 236
 Crickets, destroying, 7
 Crocus-holder, cheap, 70
 Crocuses—new and old, 22; Sparrows destroy, 110, 189; what destroy, 153; transplanting, 193; destroyed by mice, 211
 Crossing plants, 78
 Crystal Palace, 316; Bird Show, 124; Flower Show, 375; Show, florists' flowers at, 393; Rose Show, 470
 Cucumber—plants, thrips on, 14; pit, 81; pit dung-heated, 423; leaf, insect on, 481
 Cucumbers—gumming in, 46; and Melons in a greenhouse, 81; diseased, 250; open air, 366; deformed and yellow, 482
 Currant-branch grub, 300
 Cuttings—over hot-water pipes, 100; for bedding, 252
Cyanophyllum magnificum, 453, 472
 Cyclamens, treatment of seedling, 385
Cypella Herberti culture, 81
Cypripedium Hookeri, 137
Cyrtanthus lutescens, 293
- DAISY-KNIFE, 378; ERADICATOR, 416
 Daisies on a lawn, destroying, 403
Dammara orientalis, 76
 Date-Palm parasite, 157
Datura Wrightii, 153
 Decorations of rooms, temporary, 149
Delphinium alpeurouides, 343
Dendrobium—mobile breaking, 283; Paxtoni shoots, 423
 Deodar seeds, sowing, 250
 Deodars, grafting on Larch, 154
 Deodorising, 472
 Devices Poultry Show, 180, 142; dottings at, 158
Dipladenia urophylla, 52
Disa grandiflora, 453
 Disas, from the Cape, 238; culture of, 240
 Dogs losing their hair, 162, 198; at the Paris Show, 406
 Dorking—fowls, 56; Silver Greys, 57; pullets not laying, 64; plumage of cock, 64; cockerels, 484
 Dorkings—Silver-Grey, 19, 104; varieties of, 463; colour of Grey chickens, 464
 Dottrell seen, 334
 Drainage, an effect of, 49
 Ducklings dying, 370
 Ducks—wild reared with tame, 39; for table, 64; eggs unfertile, 162, 426; keeping, 302; lameness in, 304; egg-bound, 304; prolific East Indian, 368, 425; Rouen and East Indian, 464; prolific, 482
- EDGING-PLANTS IN KITCHEN GARDEN, 233
 Edinburgh Horticultural Society's Show, 245
 Egg—producing age of fowls, 20; fertilisation of, 320
 Eggs—shell-less, 86; do acorns discolour? 159; preserving, 286; mossy-havoured, 354; not hatching, 408; chilled, 482
Encephalartos horridus, var. *trispinosus*, 293
 Endive culture, 265
 "English Botany," 120
 Entomological Society's Meeting, 78, 174, 281, 330, 438, 477
Epacris culture, 4
Epacris done flowering, 383, 385
Epipsy, Mugwort used as a cure for, 416
Escallonia macrantha, 52
- Euphemia*, undulated, 320
Euryops punctatus, 368; hardness of, 434
 Evergreens—bed of, 35; for paling, 103; cutting-in, 233; watering, 447
 Exhibition poultry, time for hatching, 406
 Exhibitor and Judge at same Show not permissible, 104
- FARMING TWO ACRES, PROFIT OF, 255
 Fattening poultry, food for, 426
 Feathered helps, 154, 172, 230
 Feet, distorted, in exhibition fowls, 386
 Ferns—in crinoline pots, 55; Gold and Silver, 55; grubs at the roots, 80; scale on, 81; in greenhouse, potting, 368
 Ferneries—shading, 210, 257
 Fertility of our soils, does it decrease? 107, 141
Ficus elastica, propagating, 301
 Fig-trees in pots, 480
 Figs—falling, 301; dropping, 385
 Filberts, pruning, 177
 Fire heat direct for heating, 111
 Firs, Scotch, fence of, 80
 Floral decorations at the civic entertainment, 455
 "Florist and Pomologist," 114
 Flower-bed arrangement—What flowers think of it, 360
 Flower garden—at Straffan, plants of, 184; plan of a small, 244; planting, 244; plan, 279, 283, 294, 378; geometrical, 363; plans, faults in, 407
 Flower-gardening, progress of, 199
 Flower-gardens, planting, 308
 Flower-pot, size of, 55
 Flower-pots becoming green, 177
 Flower-stands, ornamental, 53
 Flowers—need new banish old? 315; old-fashioned cottage, 340
 Flue—cleaning a greenhouse, 7; heating, 135, 141, 181, 211, 214, 268; piea for the old, 292; cleaning, 403, 425
 Flues—v. hot water, 223; two to one furnace, 301; versus hot-water pipes, 326, 358; cheap, 330; heating by, 414
 Foliage v. flowers, 372
 Forcing, preparations for, 103
 Fountains, 343
 Fowls—dung for Roses, 198; yard for, 286; profitable, 464
 Frame—dug-heated, 234; use of a cold, 351
 Frames, protection for hotbed, 53
 French vegetables and fruits, 431
 Fruit—room management, 55; tree training, Du Breuil's mode, 90; trees, protecting, 188; buds deformed, 193; blossom-buds, thinning, 229; flavour of, 274; trees in pots, 295, 346; raising, Van Mons theory, 297; growing, 309; trees, replotting yearly, 456
 Fruits for an east wall, 123
Fuchsia seedlings, 103
Fuchsias—Sanspareil and Hercules, 137; hybridising, 327; retarding, 386
 Fumigating, 213; with tobacco, 193
 Furze as food for animals, 63
- GAINES' PLANT SALE, 342
 Galvanic plant-protector, 208
 Game—fowls, 87; garden injuries by, 156; selling live, 162; paste, Day's, 286
 Gapes in fowls, 387
 Garden—abundance from a small, 94; engine, 242; plans, 328; helps, 347
 Gardeners—a few words to young, 287; Company, suggestions for, 189; Society, 221, 283, 305, 342, 473; excluding from exhibitions, 451
Gardenia culture, 48, 376
 Gardening in defiance of difficulties, 389
 Garnishing, ornamental leaves for, 337
Garrya elliptica, 171
 Gärtner, vindication of, 93
 Gas—heated boiler, 81; lime manure, 123; heating by, 319; refuse as a manure, 379
- Gastrolobium calycinum*, 136
Genetilis tulipifera, 132
 Geometry applicable to gardening, 295, 313, 379
 Geranium—Mrs. Pollock, become green: cuttings of variegated, 122; Tom Thumb's leaves blanched, 283; Golden Chain, potting, 300; Reidii, 403; bedding for cold districts, 403
 Geraniums—new bedding, 3; Scarlet in boxes, 14; bedded, 35; Scarlet, in pots, 55; cross-breeding, 88; spotted, 158; bedding-out varieties, 234; management of young, 249; Golden Chain, &c., 385; cuttings of sweet-scented, 386; retarding, 386; new bedding, 412
 German Asters, blight on, 386
 Gilliflower, the true, 275
 Gishurst Compound, 32, 264, 280; painting with, 35; effects on blossom-buds, 204
Gladioluses in pots, 81
 Glass case, plants and Ferns for, 384; leaves spotted, 385
 Glass—paint to shade, 141; for greenhouse, 214
 Glazing frames, 177
Gloxinia tubiflora, sowing, 158
Gloxinias, culture of, 123; in thumbs, 141
 Golden Chain Geranium, its edge, 283
Gompholobium barbigerum and culture, 313
 Good manners in visiting a garden, what are? 345
 Gooseberry-buds, to preserve from birds, 187
 Gooseberry caterpillars, preventing, 141, 154; buds and small birds, 141; caterpillars, 193; destroyed by white hellebore, 223
 Gooseberries, bottling, 333
 Gooslings, detecting sex of, 40
 Gourds, 233; on poles, 25
 Grafting, 212
 Granite, imitation, 119
 Grape—growing in America, 72; judging, 100; Early Archerfield Muscat, 323; Trebbiano, 482
 "Grape Vine," 343
 Grapes—on New Year's-day, 11; keeping late, 13; new, in January, 47; old v. new, 71; in August, 81; weight of crop, 104; shrivelling when in bloom, 221; spotir, 368; spotted 423; shanking, 411; bunches dying, 442; colouring, 461
 Grasses for Queensland, 157
 Green Gage stalks yellow, 283
 Greenhouse, construction, 35; building, 45; heated from kitchen boiler, 224; wall climber, 250; gardening in a smoky locality, 397
 Greenhouses, heating, 359
 Grouse, Pintailed Sand, destruction of, 482
 Grubs in flower-pots, 250
 Guano—quantity per acre, 103; water, 481
 Guava jelly, 406
Guilandina Bonduc, 173
- HERMANIUS NATALENSIS, 343
 Hag-berry tree, 214
 HAMBURGH—fowls, Black, 106; Silver-pencilled, feathers, 126; chickens dying, 406
 Hamburgs—Silver-spangled, dead 20; points in Silver-spangled, 426
 Hams, cooking, 336
 Hants, North, Poultry Show, 404
 Hatching, ill-success in, 481
 Hawthorn, early blooming of, 325
 Hay, weight in a cubbyard, 162
 Heath cuttings and summer culture, 234
 Heaths, raising hardy cross-bred, 43; three varieties, 293; after flowering, 368; potting, 392
 Heating—horticultural buildings, 111; by flues and hot water, 135; Polmaise, &c., 136; by flue, 141; garden structures, 172, 176; respective merits of hot water and flues for, 131; Polmaise system of, 186; glass structures, 397, 400; garden structures, 411, 435, 452
 Heckmondwike Poultry Show, 18
 Hedges, evergreen, planting and trimming, 100
- Helps, garden, 263, 293
 Hen egg-bound, 370
 Hen-house, moveable, 59
 Hen's eyes swollen, 236
 Hens—not laying, 144; laying soft eggs, 144; sitting, preventing, 252; fed on insects, 159; broody, 162; with wounded backs, 326; dying without laying, 336; for early sitting, 354
 Herbaceous plants—naming, 230; list of, 442; succession of flowering, 476
 Herbs, a chapter on, 338
Heterotropa parviflora, 343
Higginsia Gheisbechtii, 419
 Hill, Thomas, on bees, 388
Hippeastrum equestre culture, 35
 HIVE, Dzierzon's improved, 19
 Hives—at the International, 62; machine for making, 62; moisture in, 159; Woodbury unicom, 160; Woodbury, made of straw, 252; Stewarton Woodburyised, 369; change of form in Germany, 369; waterproofing straw, 369
 Holly hedges, planting and trimming, 100
 Hollyhocks, propagating, 385
 Honey—season, 236; taking, 464
 Horse Chestnut, 96; double-flowered, 119; leaves injured, 403
 Horticultural Society, Royal—library for, 22; Fruit Committee, 71, 291, 341, 396, 455; should have country meetings, 87; proposed change of officials, 94; country meetings of, 129; annual meeting, 132; accounts, 145; report of Council, 150; Show, 164, 219; schedules for 1863, 182, 203; garden, 201; Floral Committee, 222, 258, 291, 341, 396, 455; reading-room, 258; Azalea and Rose Show, 288; sculpture, 341; Exhibition, 391, 443; Florists' Flowers at, 411; management, 455
 Horticulture, l'Exposition de la Société Impériale et Centrale, 373, 431
 "Horticultural Society's (Royal) Proceedings," 473
 Horticultural Shows in North of Ireland, 25, 69
 Hot-water pipes—v. flues, 9; plants over, 115; quantity useful, 267; and doorway, 319; common error in fixing, 326; surface required, 412; heating by, 436, 452
 Hoya culture, 351; carnosia culture, 177
 Hunt, Leigh, gardening in prison, 309
 Hutton versus Munn, 58
 Hyacinth—Show, Hendersons', 257
 St. Francisco, 419
 Hyacinths, 204; in pots, 110; Cut-bush's, 225, 243; new varieties, 225; flowering unevenly, 268
 Hybrid Pheasants and other Game birds, 59
 Hybrid plants recurring to their originals, 182
 Hydropult, the, 203
- ICE-KEEPING, 14, 66; HOUSES, AMERICAN, 31; ventilation of, 32; houses and ice-keeping, 119; trade and manufacture, 419
Imantophyllum miniatum, 343
Impatiens bicolor, 229
 Incubator, 126
 Indian seeds, 250
 Indiarubber tubing, vulcanised, is it injurious? 295
 "In-door Gardener," 453
 Insect-destroying compounds, 14
 Insect enemies of the Chrysanthemum, 239; on plants in vinery, 250
 Insects—to destroy, 290, 472
Ipomoea Learii not blooming, 169
 Ireland, a few days in, 183
 Ivy pruning, 301
- JAPANESE FOWLS, 461
 Japanese plants, acclimatising, 162
Jasminum grandiflorum in greenhouse, 141
 Jeans, Rev. George, 272
 Jedburgh Poultry show, 103
 Judging garden produce, 403
 Judging plants, 170; fruits, 171
 Juniper hedge, 101

KALMIA, LATIFOLIA NOT BLOOMING, 333; not flowering, 331
Kendal Poultry Show, 36
Kidney Beans, forcing, 156, 284
Kitchen garden, seeds for, 134
Knowledge, importance of general, 236
Kohl Rabi sowing, 233

LABELS, GLASS, 81
Lady Gardeners, 338
Lancashire workingmen botanists, distressed, 9, 53, 78, 137, 191, 297
Lapageria rosea not growing, 423
Larch, diseases of the, 354
Larks, 302
Lawn—weeds on, 104; mossy, &c., 250
Lawrie Todd, the real, 127
Laying, promoting, 86
Lessons learned last year, 6
Lice in fowls, 320
Lilies, removing white, 404
Lilium giganteum culture, 453
Lime, 13
Lime water, 141
Limekiln's influence over Potato crop, 101
Limekilns, heating by, 278
Liquid manure—strength of, 25; for *Roses*, &c., 266, 267; smell from, 403
Liquid manuring, 177
Liverpool Poultry Exhibition, 82
Lobelia—kermesina, 301; light blue, 385
Lobelias, new, 108
"Long Firm," a member caught, 179
Lothians, the season in, 311
Love-letter—a gardener's, 380; reply to a gardener's, 418
Lycloplegium pubiflorum, 293
Lycopodium—denticulatum, propagating, 177; *Lyallii* not prospering, 267
Lyons, Lord Cloncurry's seat, 261, 277

MALAY FOWLS, 236, 251, 284, 334; colour of legs, 252; points of, 196; at *Dezires*, 268
Manchester Poultry Show, 15, 82
Mangold sowing, 233
Manure, to convert sods into, 193
Melon—culture, 9, 23; house arrangements, 81; pit, heating, 158; forcing, 214; frame arrangement, 266; leaves spotted, 333; culture, 366; leaves diseased, 384
Melous scorched, 351; small, falling, 423; heat needed, 423; retaining old, 461; thrips and red spider on, 461
Meteorological notes (1862), 7, 346
Meteorology of 1862, Lancashire, 49; Frome, 76; Warrington, 95; Bradford, 188; Bedfordshire, 225
Meyenia erecta turning yellow, 266
Mice—barking Hollies, 80; field, to trap, 115; catching field, 162; injurious to Vines, 183, 186; attacking Strawberries, 318; garden, 475
Mignonette, forming tree, 273
Mimosa viva, 173
Mimulus—maculosus, varieties, 419; cup-eus and culture, 472
Mint, variegated, as an edging, 81
Mistletoe on the Oak, 69
Moles in Vine-borders, 333
Monochætum, 214; *Humboldtianum*, 229; *Free-flowering*, 293; ensiferum culture, 461
Moore, Dr., of Glasnevin Gardens, 250
Moss-house, climber for, 81
Moths, preserving woollens from, 216
Mount St. Bernard gardening, 389
Mouse and dog, friendship between, 211
Mowing machines, 481
Mule birds, 84
Mule cage-birds, 126
Musa Cavendishii, its fruitfulness, 399; weight of fruit, 438
Mushroom—culture, 13, 349; house, constructing and managing, 428
Mushrooms grown in pots, 400
Myrtles not flowering, 403

NAMES, SENSATION, 254
Nantwich Poultry Show, 123, 143
Naturalists' Society, West Riding, 180
Nectarines—cutting back, 319; falling, 385
Nemophila, Disk-shaped, 293
Nerium flowers falling, 214
Newton, Sir I., a gardener, 389
New York—garden trees, &c., at, 174; florists and flowers, 381
Nierembergia gracilis, is it hardy? 275; hardness of, 290; wintering, 341
Nightingales, rearing young, 454
Nile, Flora and map of, 422
Novelties, forthcoming, 337
Nursery grounds, rule for rating, 277
Nurserymen's greenhouses, rating, 223

ENOTHERAS ACAULIS AND NANA AS BEDDERS, 368
Olive, grafting the wild on the, 360
Orach, Purple, as an edging, 103
Orange—tree blight, 122; tree shoots dying, 177; trees, pruning, 233; trees, repotting, 319; tree not thriving, 384; tree leaves falling, 441
Oranges—Tangerin, 5; to graft, 193; large, 360
Orchard-house—fruit, 49, 308; trees, 310, 314, 339; management and failures, 355; in the Highlands, 356; uses of, 359
Orchard-houses, 220, 290, 295, 377; bees in, 247; merits of, 276, 327, 398; invitation to Mr. Robson to view, 324; what are, and what to expect from, 379
Orchards or orchard-houses? 309
"Orchidaceous Plants, Select," 136, 316
Orchid—culture and cross-breeding, 206; impregnation, 217
Orchids—in conservatory, 141; treatment of neglected, 234; fertilisation of, 237, 287; winter-flowering, 271; sale of, 274, 314; microscopic examination of seeds, 288
Owl—which destroys game? 285, 319; does it destroy game, 420

PACKING PLANTS FOR ANTIPODES, 233
Paint—for greenhouses in smoky towns, 268; for posts, 301
Palm, a hardy, 455
Pampas Grass, planting, 100
Pancratium mexicanum, 56
Pansies—new, 2; *Impératrice Eugénie*, *Harlequin*, *Admiration*, and *King of Italy*, 76; their merits, and new ones, 89; list and management, 169; Mr. Thomson, of Iver, the improver of, 326
Pansy—Beaton's Good-Gracious, 26; the "Good-Gracious," 51, 76, 93; history and future prospects, 239; its first improver, 275; flowers injured, 441
Paris, jottings from, 373, 431
Parrot picking-out its feathers, 86
Parrotquet, Australian, 354
Parquets, Roselle, nearly featherless, 304
Parsley management, 204
Passion-Flowers in a glazed porch, 193
Pavetta borbonica culture, 441
Pea culture, 317
Peach—trees in bad order, 14; and Nectarine trees in orchard-house, 49; tree branches dying, 81; house, cleansing, 140; trees in bloom, 141; trees in bloom, treatment, 157; cracking at the collar, 158; trees, failing, 187; in unheated house, 233; tree fly, 299; aphids, the brown, 311; trees, cutting back, 319; tree aphids, 480; seedling, 481
Peaches—not setting, 301; falling, 385; mildewed, 423
Pear—Huyshe's Victoria, 76; trees unfruitful, 81; *Beurré Superfin*, 91; *Calebasse*, 137; a monster Californian, 174; leaves, fungus on, 333; *Nouvelle Fulvie*, 343; tree not bearing, 385; tree, blighted leaves on, 403; British Queen, 419; leaves spotted, 423

Pears—this winter, 8; keeping this season, 28; crop of 1862, 113; new vary on different soils, 113; on Ash stocks, 158
Peas—succession of, 45, 101, 102, 109, 232; effects of crossing, 93; and how to grow them, 465; time between sowing and gathering, 465; preserving green, 464
Pelargonium—Fancy specimen, 170; culture, 214; garden, 436; training for exhibition, 474; black on leaves, 482
Pelargoniums—for forcing, 14; bone-dust for, 56; lists of new, 67; *Monitor*, *Queen of Whites*, *Regina formosa*, *Confagration*, *Royal Albert*, *Belle of the Ball*, and *Royalty*, 137; cross-breeding, 158; improvement, Censor, and *Souvenir*, 343; cuttings of *Kollisson's Unique*, 382
Pens for poultry, 15
Perennials, to sow, 399
Perilla-bed, edging for, 404
Periwinkle, Lesser, double, 263
Peruvian Bark trees, 434
Petunias from New York, 327
Phedranassa obtusa, 137
"Phantom Bouquet," 230
Pheasant—hybrid between Silver and common, 40; and fowl hybrid, 82; and Silver-Pheasant hybrid, 159; feeding-trough, Crook's, 351
Pheasants—hybrid, 59; rearing Silver, 320; young ones seen, 361
Philodendron Simsii, 345
Phylloperistron Society's Show, 58
Phyllaea Herberti culture, 81
Pyrsoestigma venenosum, 341
Picotée Jessie, 229
Pigeon—nests, 20; diseased, 354; hen not laying, 338
Pigeons—Runts, having colds, 64; Tumblers with diseased livers, 64; with overgrown bill, 159; point in Turbit, 270; Powers, a hint, 302
Pigs, salt for, 20, 63
Pinelea spectabilis propagation, 122
Pine Apple leaves decaying, 301
Pine Apples, white scale on, 14
Pinus seeds, sowing, 177
Piping required for hot-water heating, 27; covering, 32
Pipes, number of return and flow, 123
Pitcairnia pungens, 76
Pit—use of a vacant, 81; heating, 176; boiler and piping for, 403
Pits and their failures, 50
Planters, encouragement to, 326
Plants, new, of the season, 108
Pleurochallis Raymondii, 419
Plumbago—rosea var. coccinea, 137; capensis now flowering, 355
Plum—Golden Esperen, 76; trees with fruit on, shifting, 394
Plums budding on Sloes, 157
Plunging material, 81
Poinsettia—pulcherrima, propagating, 391; for garnishing, 337
Polands, white crests of, 126
Pollen's influence on seed's appearance, 70
Polmaise system of heating, 186
Polyanthus seed sowing, 118
Polygala Dalmatisana culture, 214
Pomegranate culture, 48
Pomegranates not blooming, 177
"Popular Science Review," 161
Potato—forcing, 34; planting on ridges, 148; the Barbadoes, 293, 330, 346
Potatoes—Mitchell's Early Albion and Lapstone, 1; culture, 1; something more about, 112; planting early, 140; merits of different, 210; forcing, 232; early, in Cornwall, 311
Potted plants, watering, 447
Potting, 460
Poultry—last year, 15; *Diary*, 42; *Club*, 82; *French farm*, 83; food required, 86, 180; for London market, 123; feeding profitably, 141; what points essential? 177; judging, 194; *Club*, *The*, 234, 250, 268, 283; keeping, 252; dying suddenly, 270; judging publicly, 361; losing feathers, 320; Shows, coming, 333; judging, rules for, 343
Primroses, double Chinese, 3

Primula leaves drooping, 80
Primulas, propagating double Chinese, 386
Propagating—bed, 3; house, 301
Protecting fruit-blossoms, 212
Protecting fruit-trees, 188
Protection for fruit trees, 14
Pullet unable to walk, 106
Pycnostachys urticifolia, 229
Pyrethrums, Mr. Salter's new double, 374
Pyrus japonica, moving large, 267
QUAILS, MANAGEMENT OF CALIFORNIAN, 252
Quercus phellos, sowing, 267
Quickset hedge treatment, 385
Quickset hedge worn out, 56
RABBIT EATING HER YOUNG, 20
Rabbits, protecting trees from, 171
Rainfall at Linton Park, 413
Main water, 14
Ranunculus, Persian, plea for, 21; list of, 22
Rhododendron—jasminiflorum, 75; culture, 224; glaucum, 226; seed, hybrids and manuring, 294
Rhododendrons, 394; propagating Sikkim, 123; lifting and cutting down, 193; diseased, 193; not flowering, 214; *Ankiandii*, 214; hardiness of, 253; culture, 254; seedlings and culture, 256; hybridising, 327; Sikkim, in Ireland, 351; *Bhotan*, 452
Ribbon-Rhodod, 312, 384
Ribston Pippin trees cankering, 467
Rocket, double, as a bedder, 419
Rookery, establishing, 9, 47, 76, 559
Rose—André Leroy d'Angers, 76; tree cuttings, 122; planting, 122; *Solfaterra*, culture, 141; *Cloth of Gold*, frosted, 202; *Comtesse Ouveaoff*, 223; trees and bone manure, 233; *François Lacharme*, 343; *Yellow Banksian*, not blooming, 372; leaves curling, 404; trees, pruning and manuring, 471
Roses—budding and grafting, 41; watering, 103; grafting, 103; old v. new, 145; pruning, 158; and Ivy against a fence, 158; pruning on pillars, 158; budding, 158; in pots, pruning, 171; mildewed in greenhouse, 177; manured with fowls' dung, 193; at Mr. W. Paul's, 291; manure water for, 301; in the suburbs, 325; effects of winter on, 325; prospects of, 326; new, 326; forcing, 410
Roupeilla grata, 52
Rump-pig, swollen, 162
Roupy fowls, 388
Rustic stumps, plants for, 385
SAGO PALM, 162
Salsafy, is it a fowl-poison? 446
Salt not beneficial to pigs, 198
Salvia patens, flowers falling, 301
Sam Slick's garden, 412
Sapindus saponaria sowing, 174
Saxifraga Fortunei, 343
Scilla natalensis, 343
Scottish National Poultry Show, 18
Scottish Ornithological Society's Show, 38
Seythe, Clarke's Patent, 382
Sea-kale—to be often renewed? 11; productive age, 47; culture, 258, 268; management, 156
Sea-side, plants for, 158
Season—mildness of, 133; in Cornwall, 154; proofs of earliness, 252
Seaweed as a manure for Asparagus, &c., 314
Sebastopol, gardening during the siege, 389
Sedum Sieboldii, 76
Shading, 481
Skimmia japonica not fruiting, 266
Slugs—eating worms, 158; destroying worms, 187; destroying, 301
Smerles, Belgian, 106
Smoky atmosphere, plants for, 266
Snake Millipede, 385
Soapsuds as a manure, 122
Sods, to convert into manure, 193
Soil—importance of fresh, 300; improving light, 481
Solanum, variegated, 76
Sonneria grandiflora, 76
Soot water, 441; syringing with, 267

- Spanish—cockered lost at the Crystal Palace, 42; fowls, breeding, 64; fowls, white, 162; fowls, large eggs from, 432
- Sparrow-killing not murder, 78
- Sparrows destroyers of Lettuce, 293; their merits, 293
- Stephanotis floribunda, 177
- Stocks, sowing intermediate, 141; of fruit trees, detecting, 158
- Stove—without flue, 56; heating by, 318
- Straffan House, 167
- Straffan, flower garden at, 188; farms at, 185
- Strawberry—forcing, 102, 176, 213, 350, 418; weight of crop, 104; manuring, 104; plants after forcing, 281; Keens', not blossoming, 329; blooms, profuse, 359; cross-breeding the American species, 418; failures, 432; beds, tanners' bark for, 454; plants, preparing for forcing, 469; at Paris, 475; millipedes in, 476, 481
- Strawberries—crossing, 45; in pots, 249
- Strobilanthes auriculatus, 209
- Styidium amœnum and culture, 454
- Sulphur burning in vinery, 14
- Summer-house, 398
- Sunderland Park and Waterworks, 92
- Swans, prolific, 425
- TABLE DECORATION, 450
- Talegalla, 162
- Tank for liquid manures, 332
- Tanks, constructing, 421
- Taunton Poultry Association, 215, 251
- Tea-making, 64
- Tenant removing buildings, 350
- Teratology, vegetable, 152
- Terrier pups, rearing, 162
- Tetradlea ericæfolia, 399
- Thorburn, Grant, 118, 127
- Thorne Poultry Show, 462
- Thrips—destroying, 35, 202; on Cucumbers, 202, 319
- Toad, eating worms, 331, 361
- Tobacco—quantity needed for fumigating, 14; fumigation, 253, 259
- Tomtit and his associates, 284
- Tortoises breeding in England, 51
- Trees for a blind, 351
- Trichomanes radicans—culture, 267; rediscovered in England, 411
- Trierythra hirta, 76, 2.9

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 41.1° and 30.1° respectively. The greatest heat, 54°, occurred on the 6th and 7th, in 1845; and the lowest cold, 6° on the 8th, in 1841, and 1861. During the period 152 days were fine, and on 100 rain fell.

POTATOES.

MORE than one answer to correspondents is contained in the following, independent of much very reliable information relative to Potato culture. —Eds.]

Place aux Dames, I say,

in answer to Mr. Bird; I am sorry I have only a limited supply of Potato sets to give away, and I cannot resist the appeal of Lady Georgina Oakley for her noble purpose. The Lapstone Kidneys, I presume, are common enough; not so, however, the Mitchell's Early Albion Kidney. I hunted out that variety when it was almost worth its weight in silver at Mr. Duncan Hairs', who formerly lived in St. Martin's Lane, London, and I have kept it well before the public ever since. I shall be happy to send Mr. Bird some very small tubers—if he thinks it would be worth his while to grow them for sets for another year—of both sorts, if he will forward me the address.

In a letter I received from Mr. Daintree a few days ago he tells me that the Lapstone with him proves very subject to the disease; and so, doubtless, it would with me, as well as every other variety, if I cultivated them on the flat. If any one would make it worth my while I would cause my whole crop of Potatoes in this cold shady garden any year to become stricken with disease; and, goodness knows, at the certain stage of their growth it is a very nervous time with me, even on the ridge system that I do adopt. But the beauty of the Lapstone is, that when the disease does affect the foliage it may be taken up carefully at an early stage of growth, and become very much improved in the ripening process by being laid moderately thin in a dark place. I ought to be able to procure sets from the allotment people here; but the fact is they are slovenly, and so mix their sorts into one indiscriminate jumble that the task to separate them would prove endless.

In answer to "PRESBYTER," and in a great measure I must necessarily repeat myself, allow me to say that I choose middling-sized whole Potatoes, which are grown under my own observation on my man Friday's allotment—a light hazel soil, and opposite in its nature to my own, which is a sound artificially-made darkish gravelly loam. The seed is now disposed in single layers upon shallow wooden trays, and secured from contact with damp in an underground cellar, having a temperature ranging from 40° to 45°; its dimensions are 9 feet by 18 feet, and it has a fair twilight produced by a glazed aperture measuring 3 feet by about 1 foot. The young

eyes on the sets are shooting well forth. I shall soon attend to the disbudding process, and leave one shoot upon those early sets which are the size of a bantam's egg, and two shoots to those which exceed that size in all cases; and by planting-time these shoots allowed to remain will become robust and dark with health, with young rootlets starting from around their bases, sturdy, so to speak, as the quills of a porcupine. Let me strictly inculcate that the trays whereon the tubers rest be kept perfectly dry, otherwise the roots which strike from the base of the shoots, instead of remaining strong and wiry, will grow away weak, and become matted together, deteriorating the stamina of the set. I trust the advantage just stated over the old enervating "spurting" and cutting method will be plainly seen. Nothing is here lost to the Potato; whatever virtue has gone out of it remains elaborated in the young shoot, and the tuber is delivered to the soil with its powers about it, in addition to a young plant with rootlets and leaves making ready to compete for the light of day, and to begin their fructifying functions without loss of time. When I plant, at each end of the row opposite to the sets I drive down a substantial piece of stake to remain there till the following year, in order to point out that the tubers of next year shall not occupy the site of this. I never use raw manure at the time of planting. Quicklime or mortar rubbish, which is spread over the surface soil and slightly worked-in just before planting-time, at the beginning of March, in a fine dry time, is what I prefer.

For early Potatoes I allow quite 36 inches between the rows, and for store Potatoes 42 inches. Strain a line from two pegs where the rows are to be, and place the sets upon the surface of the soil at a foot distance for the earlier and 18 inches at least, if the ground is good, for large late sorts. Then readjust the lines to the full width of a rather-worn spade, and mark out for a trench centrally between the two rows of Potatoes. Cut down rather slantingly inwards, in order to leave the sides even, and cast out every other spadeful right and left, though not exactly plump on to the shoots of the sets. The crumbs that are afterwards shovelled out take that central position harmlessly; and we then have a trench formed nearly a spit deep, which is intended to become occupied with the Cabbage tribe anon. Formerly, as each trench was finished I used to introduce raw dung, and dig that into the bottom; but now I merely fork-up the bottoms of the trenches with a three-tined fork I had made on purpose, as, having a good supply of liquid manure (house sewage) I use it bountifully instead when the plants have attained to a good size.

In this garden, which is partly overlooked by the living-room windows, I like to see everything appearing ship-shape; but raw dung hauled about a space of ground after the Potatoes are taken up, and then followed by the planting-out of lanky Broccoli plants, &c., is never pleasant in the height of summer either to the nose or eye; and under the most favourable circumstances the plants will take a month or six weeks to recover themselves and to

look decent. But by the trench rule they can be planted out expeditiously at their proper stage of growth without being kept waiting for the Potatoes to come off, and they seldom incline to club with me in the trenches.

Again, how seldom do we find the earthing-up of Potatoes done properly, or at the proper nick of time. In the above system the practice is quite superseded, for from the moment they are planted until they are lifted, nothing in that way is required, because quite sufficient soil is cast upon them in the first instance, which also insures their non-appearance above ground until the first or second week in May, when danger from frosts is over, and we may fairly anticipate their ripening to have become accelerated a fortnight or three weeks.

Formerly I allowed the haulm of my Potatoes to fall down on each side the ridges, but I found that with the later sorts they interfered with and muddled-up the occupants in the trenches; so to obviate this I now drive stoutish stakes on each side of the ridge, 5 or 6 yards apart, and strain a line of tar cord to them to retain the haulm in an upright position, and, perhaps, once or twice I clip off with the garden shears the overhanging points, should they become too long and dense so as to exclude the light and air from the Cabbageworts. The clippings I clear away in a basket, when I take the opportunity to clutch away any stray weeds above, and to catch and kill the caterpillars from off the Cabbage tribe below—a very necessary procedure. From several years' experience of the system, the conclusions I have arrived at are—when a dry season arrives the tubers have a larger and moister bulk of soil to grow in; should a wet season occur, the water drains well away into the trenches; and nearly a double surface of earth is gained for the beneficial influence of atmospheric action. When the Potatoes are lifted a quantity of soil falls down, which creates a first moulding for the Cabbageworts, which appear a healthy and flourishing crop upon the ground at once; a little drawn they may be, but the open exposure soon rectifies all that, and it is astonishing the produce that we get from this small garden under the above system.

In reference especially to "PRESBYTER'S" inquiry about planting distances, I will urge him to observe, that the sets are to be dropped from 12 to 18 inches apart, according to their size and sorts, and the rows for store Potatoes must be 42 inches apart; but 6 inches between each two ridges in the calculation which he requires, must be subtracted for trenchwork, to the account of the Broccolis; 8 inches would be a fairer measurement, but it would complicate the calculation; so let it go at 4 square yards of land to 31 lbs. of Daintree's Seedling Potatoes, which would be about 16 tons, or rather better than 223 sacks, at three bushels per sack, per acre. This is about the average the garden has produced this year, and a very good crop it was, the best I ever had; in fact, so good that I routed up the Broccoli and determined to treat the quarter to a fallow, and a thorough trenching. I can liken the ground now to nothing so much as "Talpa's" field. I suppose you have read "Talpa," and seen the illustration of that immortal harrowing by Cruikshank. Everybody should read and digest "Talpa," and then they will be able to conceive all the more easily how it is that I succeed so well in growing Potatoes.

"There, now, that is very good," some people may say, "he is comparing his small garden to a field." Be it so, yet if I can throw out a useful hint to my fellow men, my object is gained. I write for cultivators of small plots, yet my facts may be suggestive to the cultivators of many acres, just as the tiny, fine-drawn spring which works a watch, so diminutive that a four-pennypiece will cover it, enlarged and applied, enables the largest ship chronometer to keep most excellent time.—UPWARDS AND ONWARDS.

FANCY PANSIES—BEST PROPAGATING-BED— DOUBLE CHINESE PRIMROSES.

At page 790 of the last Number of this Journal there is a chapter on the "Portraits of Plants, Flowers, and Fruits;" and the bottom paragraph of it, on that page, is about Pansies from the "Florist and Pomologist," the Number for last December, where the kinds are very beautifully portrayed in their gayest colours; and there the flowers are rather larger than the biggest of the florists' kinds, but not quite so much after Euclid as a florist could exhibit them if he had undertaken to dress them up for show people, or for the chance of a prize from the Floral Committee. The Floral Committee, however, do not always go the length of their tether in the direction of Euclid, for they

had given first-class prizes already to some of these very beautiful Pansies, as well as to a pin-eyed Primrose, and to other primitives and primeworts of the school of roundabouts; and by so doing they have made a better impression on their fellow labourers, and, probably, on the bulk of the exhibitors of "the first instance," than you or your humble servant could have anticipated in so short a period. There is no need, therefore, that I should apologise for writing about my own favourite race of Pansies, or to apprehend that I shall ever be called over the coals for going at them at the very first opening of the budget for the new year.

It was only three years since that I was so intent upon Fancy Pansies that I had a whole collection of them from the very fountain-head of the race in Yorkshire—Mr. Dean, of Shipley—who has done more to soften my feelings towards the florists than even the liberality of the florists on the Floral Committee. But it is not so much for that collection of beautiful Fancy Pansies that I am going to open the new year, as for one kind of Pansy that was in that collection; for that one kind has brought me more grist to my mill at Surbiton than all my seedling Geraniums, which I distribute among my neighbours by the score every autumn after they are skimmed by the dealers.

It was the Magpie Pansy that proved so lucky to me. Mr. Dean sent me word to look after the Magpie and see what I could make of it. I did look after it, and, instead of making something of it, I have been made more of myself on account of it than ever I was about any plant which I ever took to before.

You can hardly conceive how passionately fond the ladies are of this Pansy the moment they see it, or how it confirms the opinion that ladies can decide about flowers on the instant by their own intuitive perception. It was only last spring I was going up the road with a Magpie Pansy nosegay in my hand, to show to a young lady who was making a new garden, when I met two ladies who knew me, and both of them let go their dresses to lift up their hands in admiration of the nosegay; and when I made my apologies for being the cause of the accidental soiling of the bottom of the dresses, they declared, on the instant, they would not have lost the sight for—no matter what. After that I found the young lady at home, and in the new garden, and then there was a repetition, all but about the dress; and nothing would do but her ladyship must have a Magpie Pansy for the new garden. Well, what to do was hard to tell. I had only five plants left me. After taking up the last pair, I meant to part with them to Mr. Salter, who first raised this beautiful flower over at Versailles sixteen or seventeen years since. So you see the age of a really good flower has nothing to do with its merits in the eyes of those who value flowers for their own sakes. But it all ended in the old way. The lady had a pair of the Magpie for the new garden, and I had five more plants in my stock than I intended; and they paid me better than all the rest, for their same now will go to the ends of the earth and be a comfort to many, which is the best pay after all. The only way to manage well in a pinch is to make no difficulty about the object; and the way to divide five plants between two people is merely to give two and a half to each, of course. But that was not the way I did. I took up the best pair for the lady, and it so happened they were all roots right up to the collar, owing to their being manured with cocoa-nut dust, which set-off the rest of my Pansies all into straw and foliage, that there never was anything like before in the family. Here was a chance! I divided the two plants into nine good ones, replanted seven of the pieces for myself, and took two fair-sized plants for the new garden; and both in the new garden and in my own the same result happened, which I should never have thought of. It was a lucky accident!

But I must bring you back to the year before last, to where I explained, once or twice, that the Magpie Pansy was only a spring-flowering plant, very like the prettiest stove plant we have—the *Torenia asiatica*; but as you may not know that *Torenia*, and as some others might not have seen a live magpie, I must tell them that it is a beautiful pied bird, a jet black, tinged with the deepest purple on the wings, with a metallic lustre, and the centre of each wing as white as snow, and that is how the Magpie Pansy is marked; there is a soft white mark on each, or on so many of the petals, and all the rest are jet black, but so beautifully tinged with the deepest purple, as to give even a tint superior to that on the wings of a live magpie itself.

Well, then, the two similar instances in the two gardens in 1862 go to prove, decidedly, that the Magpie Pansy is, or may

be, made a summer flower to hold on to the end of September. When it was only a spring flower it moulted, as it were, in June, and lost all the white, and without the contrast of the white it was no better than a blackbird after midsummer. Now, however, by dividing the plants late in April, instead of late in the previous autumn, as has been the usual custom, the growth of the plant is continuous, and has no rest for moulting; so the interesting contrast and the lovely tints of the Magpie Pansy may be richly enjoyed to the very end of the flower-garden season. The plants, then, are to be cut back and left as they are the whole of the winter, and on to the last week in April. Another lot might be cut back at the end of July, and be replanted or not a month later—say on a dripping day towards the end of August, and such plants in a favourable spring would be in bloom as the March Crocuses were going off.

If I had known all this in time, and had been aware the Editors of the "Florist and Pomologist" contemplated a plate of Pansies, I would have told them the story, and suggested to them to have added a figure of the Magpie on that plate. But now I have almost as pleasant a task—namely, to recommend every one of my readers to be on the look-out for the Magpie Pansy, if they have it not, and, to make their own plates full at home, to order the four kinds of Pansies which are so well set off in the plate in the "Florist and Pomologist." The names and colours are at the aforesaid page of this Journal (page 790); but as a good tale is not the worse for being twice told, I may just say that I was present when a first-class certificate was awarded to Mr. Dean for Princess Alice, the very largest and best of the white-faced Pansies, with a deep purple centre. The next two, Mrs. Moore and Leotard, I have not yet seen alive, but they are extraordinary, particularly Mrs. Moore, which has the bottom and two side petals deeply banded with the same crimson tint as one sees now and then in some of the crimson Nosegays. The ground colour is yellow, splendidly shaded with the feathered deep purple blotches in the centre, and straw-coloured back petals edged like the new tricolor Variegated Geraniums; and Leotard is as a noble in court costume, the rest of the dress being a rich shade of mauve, with the robe in Bishop's purple, and the rest to match. The last figure on the plate is the Double Purple, which has before been noticed in these pages, and which the "Florist and Pomologist" rightly says "is not new, and was known many years ago; but like many other hardy plants of great beauty, it has been neglected because it did not happen to bask in the sunshine of popularity. It is, however, a charming border plant, and should be in every garden. Our sample for figuring was obtained from Messrs. Carter & Co., who, we understand, have been successful in becoming possessed of this long-lost and ornamental variety, which is likely now to be appreciated for its own merits, regardless of the stringent rules of the florist."

All this is from the heart and hands of the "Florist" itself, being another remarkable proof of what I have just stated about the liberality of the florists of the present day. "Stringent rules" are quite right and proper when volunteers are out on parade, but sadly out of place when they are among the ladies on gala days, when the stringent rules should all point to how to please them the most.

I will now tell you how this Pansy can be made more pleasing still. I had that plant in my hands before any of the commercial people had ever seen it, or, at least, I had cut flowers of it from our office; and it is the very plant for which I had the first-class certificate from that flying quorum of the Floral Committee on that show day, when I was handing it about in ecstasies at finding that every lady to whom I had shown it was also "charmed" with it. And what will Mr. March, the author of that charming book on drawing-room decoration, say when he sees such additions for his tasteful designs as these, the Magpie and Leotard Pansies? The misfortune for me is, that my garden is so rich now that few Pansies can stand it without being staked; but I shall certainly place Leotard for its colour, and Double Purple for its ladylike setting, side by side with my most favourite Torenia-like Magpie Pansy, and I shall not cease telling every move they make until the whole country is full of their charms.

The next entry in my day-book, is a promise I made last year that I would tell how the double Chinese Primroses are made into huge specimens hereabouts, and in no place more so than in the Kingston Nursery. There is nothing about London which can come near to them. Last week I measured the largest plant here on purpose for this notice, and the diameter of the

plant was within a fraction of being 1 yard across; and there were thirty-two crowns, or divisions, in that one plant, or, as one might put it, thirty-two good cuttings could now be made from that plant, without touching the spread of the branches as I may call it.

Now, then, let us take one of those thirty-two cuttings, and go on with it for the next three years, and if we can do it as well as they do them at Kingston, we shall not be much short of a yard-through plant by the end of the period. First of all—say the very best propagating-bed that could be made, or 18 inches thick of the cocoa-nut refuse *over an open tank*, or tank-bed, for that is, without the smallest doubt, the very best way that has yet been tried and proved, for it has been proved at the Royal Gardens at Kew. When a body of the stuff is once warmed to 80° or 90°, it will keep to that degree for a very long period with the ordinary care of keeping a greenhouse warm; but over a close tank, or over rubble and hot-water pipes, it is ten times worse than useless, for I have proved that part of the play myself. Once get the bottom of the cocoa-nut dust quite dry by the dry heat from a pipe or flue, and you might just as well endeavour to drive heat through a two-inch deal board. Charcoal itself is a better conductor of heat than this stuff; but keep its own natural moistness in it by the vapour from an open hot-water tank, and there is no other substance will come near it in its capacity for receiving heat and for retaining it the longest. All that has been already perfectly proved.

Suppose, then, such a propagating-bed, and such a cutting from a double white or red Chinese Primula, and a thumb-pot full of very sandy peat, with the usual covering of white sand on the surface, not neglecting a fair drainage, and the cutting put in and watered on a fine morning in February. When the pot has drained off the superfluous water and the cutting is dry in the leaves, the pot is plunged in 85° bottom heat, and for the next six weeks the heat is not one degree lower than at first, and may be a little more at times. The bell-glass over the cutting is twice as large as the thumb-pot would seem to require, in order to allow twice the usual space over the cutting, which makes it four times less liable to damp-off than under a very tight fit. But ere the end of the six weeks there are roots, and it is necessary to tilt the bell-glass a little from sundown to breakfast-time next day, until at last the young thing is able to stand upright of itself; and before the roots get crowded in the cutting-pot the plant is shifted into a No. 60-pot, and a little leaf mould and loam are given with the sand and peat. The pot is now plunged in another hotbed, but not nearly so hot as the first; and in a very short time the second pot is full enough of roots to need another shift, and that is into the next size, or No. 48-pot. More loam again, and leaf mould, peat, and sand, and the pot and plant are now fit to stand on a shelf across the cold end of a stove. By the time No. 48 is squeezed into No. 32 the plant is fit for the greenhouse, and we are at Midsummer-day. One more shift into a No. 24-pot brings us on to the middle or end of August; and two-thirds of the compost are now the best maiden yellow loam, and the one-third about equal quantities of leaf mould, peat, and sand. From going into No. 24-pot, all through the winter and next spring, give no more water than will keep the plant from flagging, and as much heat only as to save from frost. Any time late in the spring, or early in the summer, when all the roots seem to have got into fair working order, the plant is put into a No. 2-pot—the biggest pot but one that is made in regular casts, or just the one-shift system. In this No. 2-pot the plant remains two years and gives two crops of flowers, and each crop is worth more money than the plant, and this has been done for years.

D. BEATON.

THE FLOWERS OF LAST SEASON.

BEDDING GERANIUMS.

SOME time since I gave a sort of running commentary on the new Verbenas which had been ushered into public life during the past season, the notes I made being from some in my own garden with which I had been liberally supplied by the raisers. I now proceed to do the same with the bedding Pelargoniums—or Geraniums, as I think they had much better have been called, and as Mr. Beaton will call them. I could not, of course, expect to find that I coincided in opinion with others who had similar opportunities of judging Verbenas, and never for once meant to say more than what they were as far as my own

judgment went, and the same remark applies to the subject of the present paper.

"It never rains but it pours;" and so now, because some person has written well and forcibly on the present style of gardening, deprecating the extravagant lengths to which it has been carried, others have followed in the wake, telling us that we must give it up altogether, and that it should only be reserved for public establishments. Now, although I have been one of those who have written most strongly against the outrageous lengths to which beds and ribbons have been carried, yet I think this is just as bad as the other extreme. What we want is a combination of both; and for those who, like myself, consider that one great advantage in a garden is to be able to gather a bouquet at any time for one's friends, it is a positive boon to have beds of scarlet Geraniums, Verbenas, and such like, always affording a supply, and always brilliant in their colouring.

The multiplicity of sorts is apt to puzzle and perplex an inquirer after such as may be most suited for his purpose; and notwithstanding that every year witnesses an accession of a considerable number, yet those which permanently remain in the more select lists are, comparatively speaking, few in number. New tints of colour are, of course, not to be easily found, and in habit we cannot get much beyond the kinds we have. It must be something, then, of superior excellence that should be marked for permanence in our gardens. Thus, although superiors to Tom Thumb, Attraction, and Punch have been over and over again announced, I think they are still unsurpassed; and although better variegated ones than Bijou have been as often promised to us, I do not think that there is one superior to it in its own peculiar shade of colour. It is somewhat large in its style of growth, but this can be obviated by pinching-back; but if we could obtain what I have not yet seen—the same good foliage and large flowers on a more compact style of growth, it would be very desirable.

Having these notions on the subject, I am prepared beforehand to receive with much caution the high-sounding characters we so often have with new kinds, and to wait for that time which proveth all things before putting off the old love. "Too fastidious," some would say; but surely it is better that a few things should be known to be good than a multitude of inferior ones passed off on us to fill up gardens and create only disappointment. The first season that a flower is to be let out there are many, who will and must have everything new, who do not care whether it be bad or good; but for the more general public greater caution must be exercised. I begin, then, with a section which seems only to be in the hands of Messrs. E. G. Henderson & Co.—I mean the very beautiful Tricolor Golden-zoned varieties, and of which we have now some very beautiful examples. I have also included Silver Tricolor kinds.

SECTION I.—TRICOLOR GOLDEN AND SILVER-LEAVED VARIETIES.

Mrs. Pollock.—Although not of the last season, yet its previous high price made it comparatively unknown. It is very beautiful; fine habit; the zone bright red, with occasional deep crimson blotches, retaining its colouring in all weathers.

Sunset.—A flower very similar to the above, perhaps a little brighter, but certainly not so good in habit; still it may be safely recommended. A bed of these varieties will, in a fine summer be a very handsome sight.

Countess.—One of the Silver Tricolor varieties. My experience of these for some years induces me to believe that they will never make effective out-of-door plants; but for pots they are very attractive, and this is one of the best.

SECTION II.—VARIEGATED-LEAVED VARIETIES.

Gold Leaf (E. G. Henderson & Co).—This style of leaf does not please me, and in my garden it was very delicate.

Mrs. Milford (E. G. Henderson & Co.).—I would give the same character to this. I do not admire them.

Queen of Queens (Bull).—A free-growing and free-flowering variety. The flowers are large, and the silver margin is very clear and distinct.

Cheerfulness (Turner).—Foliage green with white margin. Flowers red and well-shaped.

SECTION III.—HORSESHOE GERANIUMS WITH FLOWERS OF SALMON AND SCARLET OF VARIOUS SHADES.

Baron Ricasoli (E. G. Henderson & Co.).—A very neat dwarf-growing variety in the style of Baron Hugel, but with

much better flowers; the zone in the leaves being dark and well defined.

Herald of Spring (Turner).—A very pleasing and effective variety; the leaves marked with a broad deep-coloured zone; the flowers large and freely produced. Very early as a pot plant, quite justifying its name. Has received three first-class certificates.

Woodwardiana.—(E. G. Henderson & Co.).—As like the preceding as two peas, but not so free-flowering.

Gem of Gems (Bull).—I grew a plant of this which would have filled a bushel basket, and it had one truss of bloom on it, and this in the same bed where the other varieties were; so that it was no excess of manure that led it to do this.

SECTION IV.—PINK AND ROSE VARIETIES.

Prince of Hesse (Turner).—Pale salmon pink; flowers well-arranged in a large even truss; the habit moderate. Suited for pot culture rather than for the open border—a remark which I believe to be applicable to all those in this section.

Some other flowers, such as the Nosegay section—Magenta, &c., I have not seen. Those which I have remarked upon here as good will, I believe, not disappoint any who may purchase them. It will thus be seen that no addition, as far as I have seen, worth mentioning, has been made to the plain scarlet-flowering varieties represented by Tom Thumb and Attraction, the more fancy colours and sections being mainly run upon. Nosegays I can see no beauty in, though Mr. Beaton will think me a heretic for so doing.

Will you allow me to correct a misprint in my paper on Chrysanthemums? For "he has this year eighty large ones," read thirty; and for, in the last paragraph "in my first section," read "his first section."—D., Deal.

EPACRIS CULTURE.

In answer to "Y. Z.," I would say that if there is no mention of this group in the three last volumes, there is plenty of writing respecting them in earlier volumes. It would not serve our correspondent to refer him to these articles, so I will tell him how to manage the nice selection of young plants he has obtained, now coming into flower, and which he is anxious to increase in size as soon as possible.

One great advantage of cultivating Epacris in mixed collections is, that they will stand rougher treatment than Ericas, and without showing any signs of mildew, which is almost sure to attack Ericas in such circumstances. Another advantage is, that most of them will bloom, or may be made to bloom in the winter and early spring months. Another peculiarity is, that as they bloom best on somewhat long, well-ripened shoots of the previous summer, like the Black Currant, the plants are generally most attractive when rather young, instead of very old and bushy.

In propagating the Epacris, I would prefer as times the end of February and the end of May. In the first case I would select firmish side shoots, and the points of long flowering-shoots, from 1½ to 2 inches in length, rather firm at the base, clean cut through there. In the second case we could thin-out young shoots after pruning, about an inch long, slipping them off with a sharp knife close to the older shoot. In both cases remove the leaves for about a quarter of an inch next to the base, and insert in silver sand in well-drained pots, as described the other week for Aphelexis, and carefully cover with a bell-glass. As extremes of temperature and of dryness and moisture are to be avoided, it will be found of great advantage to have a glass case inside of a propagating-house, beneath which the propagating-glasses with their pots and cuttings may at first be set, and then, in three weeks, plunged in a mild bottom heat. When struck, four plants may be potted round the sides of a four-inch pot. The next spring each of these plants may have a three-inch pot, and the season following a four or five-inch pot. I presume that it is such plants that our correspondent has obtained; and in general it is by far the most economical to purchase such plants from nurserymen who make propagating a principal feature in their trade.

The best Soil for Epacris is good heath mould lightened with silver sand. For small plants in the smallest pots, the soil should be rather fine. As the pots and the plants get larger the soil should be rougher, so that for a seven or eight-inch pot there may be many pieces as large as fair-sized marbles,

and some of the very dusty parts of the peat should be excluded before the silver sand is added. For such plants as require from an eight to a ten-inch pot, the soil should be three parts of good fibry sandy peat, and one part should consist of equal parts of silver sand, rough pieces of charcoal without dust, and broken pieces of pots also without dust. In such sizes there may be pieces of soil as large as walnuts; in six-inch pots, pieces as large as Mazagan beans; whilst in smaller sizes, the rough pieces should be little larger than peas.

Watering.—As a general rule pure rain water is the best, and the plants should never be very dry. The quantity of water required will be regulated by the weather and the state of the plant. When resting after pruning, little moisture will be required; and a rather-close atmosphere, and a skiff from the syringe overhead, morning, noon, and night, will be better than much watering at the root. Most water will be needed when the plant is making its new wood, and when it is in bloom. At these periods weak clear manure water, made from cowdung, sweet, and from twelve to eighteen months old, will be an advantage. No artificial manure should be trusted unless very weak—as one ounce of guano to at least six gallons of water.

Pruning.—This should be done as soon as the plants have finished, or have nearly finished, flowering. Take care that the plants are not extra-watered beforehand. The mode of pruning depends on circumstances, and what is chiefly wanted. Bear in mind that in no case, except very young plants, will they bear the wood to be cut that is older than one season's growth. A clever young fellow once did me out of a good collection in a few minutes by using his knife on well-established plants as if they had been so many willow stools. It is safest to confine the pruning to the shoots of last season's growth. In the case of our correspondent, who wishes large specimens as soon as possible, I would, as a rule, prune back these shoots to from 4 to 8 inches from their base, put a string round the rim of the pot, and with threads bend these shoots to it, so as to cause them to break somewhat regularly all over. This will secure a plant well stored next season with a great many flowering-shoots; but there will be few shoots covered with flowers from 12 to 20 inches in length. To secure these fine long shoots of bloom, the bulk of the young shoots now should be cut back when done flowering to 2 or 3 inches in length. In fact, for this purpose I have often treated them as willow stools—never touching the old wood, however, as my man did unmercifully, but cutting-in the young wood pretty closely every season. Something of the first plan is the best for symmetrical specimens. As already hinted, the plants after pruning should have a rest for a fortnight or so—that is, should not be excited by extra heat or moisture.

Time of Repotting.—The best time is when the new shoots are 2 or 3 inches in length, after pruning. Care must be taken that the roots are moist previously, and the plants should be kept close and be sprinkled overhead, and shaded from bright sunshine until the roots and tops are progressing freely, when more air and light should be admitted by degrees.

General Treatment and Position.—In winter the plants should occupy an airy position in the greenhouse, which should seldom be below 40° at night, and seldom above 50°, with a rise from sunshine of from 10° to 15°. Water to be given according to weather. Frosty air to be kept from beating directly on the plants. After pruning set the plants together, and be careful not to overwater. In a fortnight, if they can be kept closer and warmer in the house, it will cause them to break more freely; if not, taking them to a house or pit where the heat would range from 50° to 65°, would be all in their favour, syringing the stems several times a-day to encourage them to break freely. Examine the drainage, and top-dress or repot as stated above. Keep the plants in a similar temperature, shading from brightest sunshine until the shoots are growing freely. Remove the plants then to a cold pit where more air can be given to them. Keep them there, if possible, all the summer under clean glass, with plenty of air back and front. In September and the first half of October leave the sashes off entirely in fine sunny weather; but if wet is anticipated, place the glass on with air on back and front. This will ripen the young shoots and cause them to show bloom at almost every joint along them, except the soft younger points. House in good time in October. If not convenient to give the plants the shelter of a cold pit in summer and autumn, the pots should be protected from the sun, so that the fine hair roots are not injured.

Of Insects and Diseases there are few that trouble the *Epacris*. The worst insect to eradicate is the white scale. If

the plants are large it is hardly worth while attempting to cure them. I once cleaned a fine large plant, much infested, by dipping it wholly in a thin paint of clay made with weak soap water. The plant was set in the shade in a close shed, and the clay was allowed to dry on the plant for four or five days; and then, when the fingers and some brushes were run through the branches, the clay and insects came away together. The plant was then well swinged in a pond of clear water, and afterwards showed little trace of the doctoring and grew well. Smaller plants might also be tried in a weak solution of glue water, or size or gum may be used. The water, if just a little sticky, shuts up the insect from atmospheric air; and it would appear that few insects can stand this so long as plants can. Few plants when growing freely can stand such treatment above forty or fifty hours.

R. FISH.

TANGERIN ORANGES.

ALLOW me to correct your report on the Oranges placed before the Fruit Committee at Kensington on the 9th ult. They were, it is true, sent by me; but, as I stated in my letter to the Secretary, from J. Stoveld, Esq., of Stedham Hall, near Midhurst.

His mode of cultivation has been the past season such a perfect success, that a few words as to the *modus operandi* may not be unacceptable to your readers.

The trees, some four or five years old, were wintered in a greenhouse with Camellias and other plants, and removed in March to a pinery, the pots being plunged in warm tan. They bloomed in April, and set a large crop of fruit. As the months of June and July were so wet and cold it was thought proper to allow them to remain in the pinery all the summer. From their first entrance into this house the trees were syringed regularly, but only on the stems and lower branches, so as to avoid wetting the blossoms, while they were in bloom. Under this treatment the crop was most abundant, so as to weigh down the branches of the trees. The fruit commenced to ripen in September, and continued to do so all through October and November.

They were larger than those usually imported, and being suffered to ripen on the trees, they were so full of juice as to make their rinds crack; their richness of flavour and fine aroma were most remarkable. In the hot summers of 1857-8-9 these Oranges ripened well in orchard-houses, but not so in 1860 and last summer; so that to cultivate them in high perfection, in ordinary seasons the trees, after being wintered in a greenhouse, should be placed in a pinery or vinery where Grapes are forced, or in any other house where forcing is carried on.—THOS. RIVERS.

CALCEOLARIA LEAVES TURNED BLACK.

CAN you tell me the cause of all my young *Calceolaria* seedling plants being affected in a manner that destroys the outside leaves by turning them black, so that there is little left besides the stem? My gardener changed the little yacht stove I had in the greenhouse to obviate frost for a larger and more close one, as he thought the leakage of the former affected his plants. Can it be the heated metal of the present stove? Two other remarks I made to him about the seedlings before this defect was observed—viz., that he watered too frequently, and pinched out the centres too early, having done this with both *Calceolarias* and *Cinerarias* fully six weeks ago.—THOS. PEARSON.

[The leaves were so dried-up before we received them, that we could scarcely make out whether the effect was produced by air burnt by an iron stove or by thrips. We think that very likely both had an influence in making them leafless. If you have read "Doings of the Last Week," you would see that Mr. Fish objects to fire heat altogether, if it can be avoided, for *Calceolarias*; and also you would find that, provided moisture and coolness be secured, they can hardly go wrong, if frost be excluded. Whenever airiness, coolness, and moisture are neglected, thrips is almost sure to seize the plants. If on examination you find your plants are much occupied with that jumping insect, the best thing you can do in their present stripped state would be to throw them away. If, however, the stems are strong, we would place all the plants close together and smoke them with the best shag tobacco; the second day afterwards place the hand over the surface of the pot reversed, and swing the head of the plant through a pail of sulphur water, or of size water, as recommended

to-day for Azaleas affected with thrips, and in a day afterwards syringe with clean water, the pot being laid on its broadside; and when the plant as respects the foliage is dry, remove a little of the surface soil, top-dress with fresh, and set the plants standing on damp moss, at the part of the house farthest from the iron stove. Here let us remark, that in using fire in these stoves, it is important that the fire should be longer continued, in preference to ever letting the iron approach red hot, as that makes sad havoc with the air enclosed. The fireplace in all iron stoves should be at least 3 or 4 inches from the surrounding case, and it is best that the fireplace be of brick.

We do not like to give an opinion about disputed points between gardeners and their employers. As respects watering, we incline to think that the gardener was right, and stopping is also a matter of taste and convenience. Where there is plenty of room, herbaceous Calceolarias and Cinerarias may be grown without stopping at all; as, if repotted as soon as the roots touch the sides of the pot, and plenty of air is given, the plants will become bushy without any stopping at all. Our border Calceolarias last season were never stopped, and no plants could have been more bushy, or flowered better; but before planting-out they were kept cool.]

CALLICARPA AMERICANA.

THIS is a native shrub found from Virginia southward but hardy in Ohio. It is very beautiful, bearing crowded small violet-coloured berries called French Mulberries by some, though not a Mulberry at all.

This, though a southern plant, is sufficiently hardy. As it blooms and fruits on the young new wood, a little winter-killing of the extreme twigs is no injury, and may be followed in the spring by the knife or shears to the manifest improvement of the appearance of this ornamental shrub.—(*Prairie Farmer*.)

[This plant is usually found in nurserymen's catalogues as a greenhouse plant under the name of *Callicarpa purpurea*. Have any of our readers tried it out of doors as a hardy plant, and, if so, will they oblige us by stating the result? It is recorded that when the plant was first introduced it was treated as a hardy plant and was destroyed by the severe frost of 1740.—EDS. J. of H.]

LESSONS LEARNED LAST YEAR.

IN reply to Edward Ollis in No. 91, I beg to say with respect to Little Dot that the stock is very small; but owing to circumstances over which I have no control, it will be parted with. And there are a few dozens of two-year-old plants; and he may venture to include them in his next spring's arrangement so far as the cost may be concerned, which will be low; but the particulars will very shortly be made known through the advertising columns of the Journal.

There has been a very remarkable omission by your correspondents—an account of their success in the floral department during the past summer. No one seems to have hit upon any good move worth recording. That the season was unfavourable for producing a grand display is generally admitted, so that most people have had just cause for being dissatisfied and keeping silent; still there have been local circumstances favourable to some plants, and even the success of one or two good and useful kinds for the summer decoration will be worth making a note of.

Some year or two ago much discussion took place respecting Calceolarias in general, and the yellow in particular. It failed very often, and spoiled the best-made arrangement. Either in the mass or in the ribbon a gap here and there was to be seen; and unless there was a good reserve kept on hand that gap would be seen to the end of the season. It was found that the yellow Calceolaria was too useful a flower to be dispensed with: hence the anxiety about the sudden failures, and the many suggestions as remedies. But who ever saw the Calceolaria do better than during the summer of 1862? I use it largely, as it is easily struck and as easily kept through the winter; and with the experience of the past summer I think it as easy to manage through the flowering season, because to do so we have only to look back to the state of the weather during the six months the Calceolaria is supposed to be planted out. From the 1st of May to the last of October there was more than an average of 3 inches of rain for each month, and pretty evenly

distributed, so that the soil could never have been thoroughly dry; at no time during the summer did the thermometer rise to 70° in the shade, and I have one of Negretti's patent maximum ones; and I have only had occasion to replace one plant, and that from an accident. Notwithstanding much rain and so low a temperature I frequently gave them liquid manure when it was raining, and nothing could have been more successful: therefore it may be presumed that the Calceolaria requires a large supply of moisture and a cool atmosphere, which, if not naturally afforded, must be artificially made.

On the other hand, I had not a solitary Balsam that I would take the trouble to plant out. *Petunias* all went to green. *Verbenas* made no progress till the latter part of the summer. *Asters* and *Marigolds* (French), were very good; *Dahlias* but middling.

My most telling bed was in an out-of-the-way piece of ground near a part of the dwelling-house. The back row was *Dahlias*; then a row of *Delphiniums* a foot apart. As soon as these had done blooming they were cut down, and a French Aster in bloom planted between each two; then two rows of *Calceolaria Gem*; then one row of yellow *Calceolaria*; then a row of variegated Mint, which kept up the *Calceolarias* nicely; then a row of *Prince of Orange Calceolaria*; next, *Scarlet Geranium*, and, although they were two-year-old plants, they became so coarse I was obliged to take them away and substitute the only plants I had—*Ageratum mexicanum*. The next row was a row of two-year-old plants of *Little Dot*. The next and outside row was *Lobelia speciosa*. That, too, grew so strong that it almost smothered *Little Dot*, and I was obliged to remove it also and substitute *Portulacas* in three-inch pots; but I am fully convinced that the original plan or arrangement would have been better if I had had a *Scarlet Geranium* with the same properties as *Little Dot*, and, if there must be an edging at all to *Little Dot*, it must be very dwarf indeed, and I think a variegated one.

Now, looking at the above bed from a distance, there were only the yellow, the variegated, and the rose to be seen distinctly in lines. And although at a distance and at a closer view it was decidedly the best display we had, I do not mean to present it as a guide to any one else; but it has proved that *Little Dot* is highly adapted, and can be depended upon even in ground too strong for any *Scarlet Geranium*, for ribbons, or for an edging, and it can be planted out at once almost to touch each other. I have proved it under a Chestnut tree, where no sun at all touched it, and no rain but what came through the tree; it is easily propagated, and it will stand more frost and other hard treatment than any other *Geranium* I have. For vases no plant could be more suitable.—THE DOCTOR'S BOX.

CELERY CULTURE.

I FIND from THE JOURNAL OF HORTICULTURE that some of its readers have been disappointed in raising Celery this season; and as I have been very successful, I will detail the way in which mine was raised.

The seed was sown thinly, using potting soil for the purpose. Either a pot or box may be used. An eight-inch pot will raise several dozen plants, and there is no use in raising more of them than are required. Place the pot or pots upon a very slight hotbed, and after the plants are up give plenty of air until they are strong enough to be pricked-off. When doing so be sure to take the very best plants and none with fewer than four leaf-stalks, as those with fewer will not make good plants. Be very careful to avoid those which have any rust upon the roots, as I have frequently found that upon seedlings of Celery when pricking-out, and if kept they will get worse. After pricking-out, the plants should be carefully shaded in sunny days and not allowed to stop growing freely, as I believe any check to their growth is very injurious to them. Free-growing healthy plants are never attacked by disease in my experience. After the plants are growing freely, give plenty of water.

I do not make the trench deep, but rather allow additional room betwixt the trenches to afford earth to supply the necessary earthing-up, and am careful to take away all decayed leaves before that is done, which should be upon a dry day and when the plants are growing freely—at least once a-week. This I believe to be one of the main preventives of the stalks decaying. I also tie the plants together with strings of old matting, which prevents the wind from breaking the tops. If the soil is coarse, a little leaf mould may be placed next the neck of the plant,

and the hand used to put the soil close to this part previously to earthing-up.

I also use very rotten dung, for I believe rank manure is very unfit for growing Celery.

I prefer any of the Red sorts to any of the White. The latter are oftener hollow and stringy.—JAMES REID.

METEOROLOGICAL NOTES, 1862.

LINTON PARK, KENT.

THE following table represents in the two first columns the highest and lowest range of the thermometer each month; the highest and lowest range of barometer; the number of days in which the wind was in each of the eight principal directions indicated, taken at noon each day; the rainfall each month, with the number of days on which it fell; also the number of frosty days; and compared with the summary of these is the record of past years, as under:—

	Thermometer.	Barometer.	Wind.										Rain.	Frost.
			Number of Days in each Month.											

The year that is past has been more remarkable for the mildness of the winter than for the heat of the summer. The number of days' frost is much below the average, while the rainy days recorded are much above it, the rainfall being above the average; the greatest fall on any one day was October 18th, .91 inch, while on the two following days 1.01 inch fell, making nearly 2 inches of rain in three consecutive days. The barometer has varied less than on most years; 30.28, on the 8th of February, is the highest range I have, and 28.82, on the 28th of the same month, is the lowest. The variation of the thermometer is also, perhaps, less than that of most years; and it is somewhat remarkable that the hottest day by 7° was May 6th, thermometer 86°. The coldest night, that preceding the 9th of February, was 16°. With regard to the prevailing winds, the above table shows a falling-off in those from the N.E., while those from the S., and also N., show an increase. The prevailing winds of the year were S.W., W., and N., counting 245 days; leaving only 120 for the other directions.

The principal features of the year may be summed-up monthly somewhat thus—viz.,

January.—Frost in the middle of the month, otherwise mild, with scarcely any snow; but the hazy rain kept the ground wet and dirty.

February.—Mild, no heavy rain, and less wind than usual.

March.—A wet month, with less wind and frost than usual.

April.—First week wet, afterwards fine and favourable; last week very warm. Cuckoo heard on 21st.

May.—First week very warm, the 6th extremely hot; the latter part of the month more dull, and less warm; nevertheless, at the end of May everything seemed forward, and promising an early season.

June.—Dull, cold, wet, and unfavourable, retarding vegetation, while the rain injured the hay crop.

July.—Not remarkable. The latter end of the month finer than the beginning.

August.—Some useful rains about the middle, afterwards fine and seasonable.

September.—The beginning and end of the month wet; the middle fine; in other respects not remarkable.

October.—First week fine, afterwards wet, with some high winds; very little frost.

November.—Not remarkable any way.

December.—Unusually mild, and the wind so high and dry on the 21st as to cause the dust to fly—an unusual thing on the shortest day. Very little frost for December.

On the character of the season in regard to the agricultural crops, it is not my purpose here to enter, further than that the harvest was later than usual, especially in late places. The wet weather setting in about the time the corn was ready to cut, and continuing throughout October, retarded that operation much. The harvest, however, in more favoured places was tolerably well got through. Of fruits and other produce I purpose saying something hereafter.—J. ROBSON.

CLEANING A GREENHOUSE FLUE.

I AM afraid my greenhouse flue is becoming stopped-up with soot, as it does not draw so well as it did formerly, nor does it give out so much heat. It has not been cleaned out since this time last year. As it would be very inconvenient, if not impossible (on account of the plants in the greenhouse) to have the flue opened and cleaned, I shall be glad if you would inform me whether I should be in danger of injuring my plants if I were to set fire to the soot in the flue, which I have no doubt I could do by putting some dry straw in the fire-hole. The flue is of brick, 9 inches by 4½, and the length from the fireplace to the chimney about 20 feet. I feel pretty confident that setting fire to the flue would so far clear it that it would work until the spring, if you think I may do so without danger of injuring the plants; I mean by the excessive heat likely to be generated by the firing of the soot in the flue.—COUNTRY CURATE.

[In such a short flue we should think you could clean it in a quiet mild day, and with only one opening, sending most of the soot to the chimney bottom, and to the furnace. It is great waste and dangerous to use a dirty flue. If done carefully the flue might be swept without dusting the plants in the least. If you were obliged to take any soot out in the house, the hole could be covered with a bag, which would prevent any scattering. Your flue being 4½ inches thick, would stand being set fire to better than a thinner flue; but we would not at all advise you to do so—not because, as you imagine, you would have too much heat from the burning soot, but because there would be such a likelihood of explosions that your flue would never be sound afterwards.]

DESTROYING CRICKETS.

A CORRESPONDENT lately inquired how to destroy them, and I recommended thin slices of bread and butter with arsenic placed on them, and then the buttered arsenic-sides placed together. I knew that once my friend Mr. Fraser, of Luton Hoo, was much troubled with them, and the plan he adopted was, he thinks, more successful. Arsenic was mixed in little balls of fat, made like good-sized pills, and these were dropped into the dry warm places where crickets were known to frequent most before starting on their depredations. At night, when the light of a candle was as quietly and noiselessly as possible thrown upon the spot, the crickets would be seen not only devouring the pills, but also, in cannibal fashion, devouring those that were already sick and dying, and thus obtaining a double portion of the poison. If once they get a-head they will destroy almost everything tender.—R. F.

PEARS THIS WINTER.

In the last Number of your Journal, I see a notice from "E. B.," of some kinds of Pears having kept unusually well this season. Mine have, upon the whole, kept very badly; but there has been very great uncertainty in their keeping. Two months ago all my Winter Nelises grown on pyramids were quite ripe, many with spots of decay upon them, and going much faster than we could consume them, while Pears of the same sort, gathered from an east wall, were perfectly green and hard, and are now just in perfection, and showing no tendency to decay.

My Duchesse d'Angoulême were also, one quantity of them, fully ripe two months ago; while another quantity gathered from another tree (both pyramids) were quite hard, and have only been finished about a fortnight ago.

Several other varieties, Beurré Diel, Beurré d'Arenberg, Beurré Duhaime, Passe Colmar, &c., have prematurely and suddenly gone bad at the heart, and become thoroughly decayed. With a few exceptions, Pears have, moreover, with me been decidedly wanting in favour this season. In my crop of Glou Morceau, I have noticed that all those which are deformed and drawn out of shape by canker are far the best, while all the fruits which are clear and perfect are very deficient in sweetness and flavour. I have this sort both on an east and west wall, but decidedly inferior this season, and many of the largest and finest fruit are going at the heart before they are properly ripe.—C. P., *Herts.*

NEW BOOK.

The Weather Book: a Manual of Practical Meteorology. By Rear-Admiral Fitz Roy. London: Longman & Co.

(Concluded from page 789.)

AT Chapter XIII. of this valuable work we come to the practical utilisation of meteorology. "Having statistical facts, and understanding their relation to our atmosphere at any given time or succession of times, we know what is occurring around us within a certain area of several hundred miles in diameter in the air and clouds that may be above or passing near us; and, not only so, we can tell, with even more than probability, what will be the atmospheric conditions within and at any part of such an area during the next two or three days." The author then gives a brief outline of the practical system at the Board of Trade, with reference to meteorologic telegraphy.

"In treating so complicated and extensive a subject as that of our atmosphere and its movements, it is extremely difficult to combine mathematical exactness with the results of experience obtained by practical ocular observation and much reflection; but to some extent this has been effected recently, the Board of Trade having arranged telegraphic and frequent communication between widely-separated stations and a central office in London, by which a means of feeling—indeed one may say mentally seeing—successive simultaneous states of the atmosphere over the greater extent of our islands was established, and an insight into its dynamical laws has been obtained, to which each passing month has added elucidation and value.

"The first cautionary or storm-warning signals were made in February, 1861; since which time similar notices have been given as occasion needed.

"In August, 1861, the first published forecasts of weather were tried; and after another half-year had elapsed for gaining experience by varied tentative arrangements, the present system was established. Twenty-two reports are now received each morning, except Sundays, and ten each afternoon, besides five from the continent. Double forecasts, two days in advance, are published, with the full tables on which they chiefly depend, and are sent to eight daily papers, to one weekly, to Lloyd's, to the Admiralty, and to the Horse Guards, besides the Board of Trade.

"The forecasts add almost nothing to the pecuniary expense of the system, while their usefulness, practically, is said to be more and more recognised. Warnings of storms arise out of them, and, scarcely enough considered, the satisfaction of knowing that no very bad weather is imminent may be great to a person about to cross the sea. Thus their negative evidence may be actually little less valuable than the positive.

"Prophecies or predictions they are not: the term forecast is strictly applicable to such an opinion as is the result of a scientific combination and calculation, liable to be occasionally, though rarely, marred by an unexpected 'downrush' of southerly

wind, or by a rapid electrical action not yet sufficiently indicated to our extremely limited sight and feeling. We shall know more and more by degrees."

As a proof of the usefulness of these warnings or "forecasts," it is mentioned that, "At a meeting of the shareholders of the Great Western Docks at Stonehouse, Plymouth, it was stated officially that 'the deficiency in revenue is to be attributed chiefly to the absence of vessels requiring the use of the graving docks for the purpose of repairing the damages occasioned by storms and casualties at sea.'"

In order to enable the reader to judge of the basis on which rules for forecasting the weather likely to occur is founded, some explanations are given, as the method is new in its combinations, although depending on old or well-known principles. For these the work itself ought to be perused; but as many of our readers will be curious to know from what circumstances these rules are mainly deduced, we shall endeavour to point out a few of the principal.

Air-currents, we are told, sometimes flow side by side, though in opposite directions, as parallel streams for hundreds or even thousands of miles. Sometimes they are more or less superposed; occasionally, indeed frequently, crossing at various angles, sometimes so antagonistic in their angular collision as to cause those large circular eddies, or rotatory storms, called cyclones.

"Whenever a polar current prevails at any place, or is approaching, the air becomes heavier, and the barometer is high or rising. When the opposite, tropical, prevails or approaches, the mercury is low, or falls, because the air is, or is becoming, specifically lighter." The north-east and south-west are reckoned by meteorologists the "wind-poles;" and all varieties of winds may be traced to operations of the two principal currents, polar and tropical, our north-east and south-west points.

Great and important changes of weather and wind are invariably preceded, as well as accompanied by notable alterations in the state of the atmosphere. It has frequently been asked, "how much rise or fall of the glasses may foretell remarkable change, or a dangerous storm?" To which can now be replied, "Great changes or storms are usually shown by falls of the barometer exceeding half an inch, and by differences of temperature exceeding about 15°. Nearly one-tenth of an inch an hour is a fall presaging a storm or very heavy rain. The more rapidly such changes occur the more risk there is of dangerous atmospheric commotion."

The barometer often, if not usually, shows what may be expected a day or even days in advance rather than the weather of the present or next few hours. By means of telegraphic communication warning can be sent of such changes all round the coasts.

Extensive changes, showing differences of pressure above or below the mean height of the mercury in the barometer, amounting to nearly an inch, or thereabouts, are certain to be followed by marked commotion of the elements in a few days. If the fall has been sudden, or the rise very rapid, swift but brief will be the resulting elementary movement. If an extensive fall or rise take place slowly, the change in the weather will likewise be gradual, but will last longer, whether for better or for worse.

At the Board of Trade, we are informed, from thirty to forty weather telegrams are received daily (except Sundays), and forecasts or premonitions of weather are drawn up for publication in the newspapers as speedily as possible. Those received at ten A.M. are examined and sent out at eleven A.M. for publication in the second edition of the *Times*, and soon afterwards to other afternoon papers. Suppose that on a given morning the barometrical readings are nearly alike, it may be not differing more than a few hundredths of an inch from Nairn to Jersey, from Valentia to Heligoland; temperature, evaporation, nearly similar, as well as the direction and force of the wind—such statistical data would show at once a settled state of the air; and as statistical alteration must precede dynamic motion, a continuance of settled weather is probable. Under such circumstances no general change of importance can occur during a day.

Mr. Glaisher's balloon ascent on the 5th of last September is noticed. He and his companion attained a height, it is said, of more than 6 miles, and they probably exceeded 7 miles, which is higher than Deodunga, the loftiest summit of the Himalayas, about 29,000 feet—6 miles being 31,680. The last registration of the barometer, before Mr. Glaisher lost consciousness, was 10 inches, and this was in the extreme cold of 57° below freezing, and in an air so rarified that the pigeons which were liberated fell like

stones. "There was no moisture, there were no clouds, for they were far above both. They were nearer to heatless, airless, and mysterious space than ever mortal man had previously penetrated." Beds of moisture (clouds or fog) lie at various heights not exceeding about two miles.

The work is illustrated by numerous plates and diagrams; and in an appendix the storm-warning signals, now so beneficially employed, are explained, together with other matters relating to the subject of the weather. Altogether it is one of the most interesting and useful publications that have appeared in modern times.

At present forecasts of the weather are limited to some days; but they may, in a time not far distant, extend to weeks, or to the season, with nearly equal certainty.

NATIONAL AURICULA SHOW.

FOR the information of the Auricula-growers and exhibitors at the National Auricula Show to be held at York, I can state that the communications I have received are in favour of five being the minimum number of pips on a truss of edged varieties, and seven on selfs. But it must not be understood that the truss is to be reduced to that number; for where a larger truss is exhibited it will be preferred, if the properties are equal.

With regard to showing the plants in the pots in which they are grown no restrictions will be made, as it is thought necessary by some to turn them out for the convenience of travelling.

I would much rather others would give their opinions; but, whilst on this subject, I cannot refrain from saying that I think the exhibitor gains no advantage by so doing. The only object in doing it, that I can see, is to save railway carriage, which is a great object to many persons; and I think we ought to give every facility for exhibitors sending their plants to and from the Show with as little expense as possible. I certainly did object to the untidy manner in which some plants were placed on the exhibition table at the late Show, which I will take care does not occur at York.

I would strongly urge those who intend to exhibit to send me their names at once, as I am desirous to get the schedules out as soon as possible.

I have been solicited to add a class for Alpines, and it would have given me great pleasure to have complied; but not wishing to encroach upon our funds, I cannot take it upon myself to do so. As I am desirous to secure a good show, I shall be happy to give one guinea to be competed for in this class.

Having had several inquiries as to the principles fixed upon for the guidance of the Judges, I may state that *Glenney's* properties of the Auricula will be the standard, a copy of which will be forwarded to the subscribers shortly.—*JOHN DOUGLAS, Davy Gate, York.*

BEGONIAS SUFFERING FROM COLD.

I HAVE, in a conservatory which cannot be heated but by a Joyce's stove at times, some Begonias that suffer much, apparently, from the damp sea air. The temperature of the house never sinks much below 40° Fahr.—*DORSETSHIRE.*

[There are few Begonias that will keep healthy at a temperature of 40°. You will succeed in keeping most of them over the winter at from 40° to 45° if they are kept just sufficiently dry so as not to be dried-up. These would lose most of their leaves, and look unsightly; but they would bloom well, and look well in summer, as the sun gave them heat enough. To look well in winter they would require a heat of from 50° to 60°. With your temperature of 40° the best you could do would be to place the Begonias temporarily out of sight, and just keep them alive and rather dry, and they will be all right in summer.]

ESTABLISHING A ROOKERY.

I SEE in your No. 91 an inquiry from a correspondent "*GATLEY*," regarding the formation of a rookery, and I beg to forward my own experience in a similar case.

My sister obtained a nest of newly-hatched rooks from a rookery very near to the trees we wished inhabited, within the distance of three or four fields, and she had carried it carefully in sight of the old birds, which followed the cries of their young. She carried it up to the top of a very high Beech, and fixed it

firmly in the fork of the upper boughs as high as he could climb; for the tallest trees are preferred by rooks, and the Beech and Elm to other species.

The old birds brought up their little ones, and a settlement was thus formed, which remains to this day. If there should be any rookery in the neighbourhood of "*GATLEY*," it might be worth his while to bestow a little time, care, and trouble, to try this experiment.—*THE AUTHORESS OF "MY FLOWERS."*

MELON CULTURE.

You will oblige me by stating how Mr. Fish waters his Melons through drain-pipes. I had a good crop this year; but after they began just turning the leaves became blighted, and brown spots came all over the Melons. They did not all turn at once, as two or three ripened. The roots I found were cracked from the bottom to just level with the soil. I had slates all over the soil, and the plants ran over them. I grew flowers in the pit with the Melons. The soil was light common garden soil mixed with rotten manure. This last month I have had two loads of stiff marly soil mixed with some rotten manure, which I have thrown in a heap, and I soak it with the liquid manure from the stable, and will continue doing so till the spring. Am I doing right? I watered the Melons between the slates, but now I think of trying Mr. Fish's plan.—*A TWO-YEARS SUBSCRIBER.*

[The cracking of the roots was greatly owing to the richness of your soil. Leaves are apt to decay if the atmosphere is kept very warm and dry. In your case we suspect that the roots were rather dry. Your preparation of soil for next year may answer in the hands of the initiated, or of those who will take care to counteract it, but Mr. Fish says it is far too rich for him to approve. He prefers soil rather stiff than light, and with little manure in it, especially if fermenting material is used. Even when ripening the roots must not be dry; but if flavour is the chief object the atmosphere must be rather dry. This cannot be the case when the surface of the bed is always moist from syringings or waterings. When the fruit, therefore, approaches maturity no watering to speak of is given at the surface, but the soil beneath is kept rather moist by pouring water into small round drain-tiles, inserted perpendicularly in the soil at back and front of the frame, about 3 feet apart, and fitting a plug into the end of the tile.]

THE DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

I HAVE received, since I last wrote, from two workingmen botanists at Manchester 5s.; from V.R., 10s.; from Dover, 2s.; from Mrs. H. Wood, Hoole House, Chester, £5.—*JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.*

P.S.—By a stupid mistake I put my address "36, Church Street" the other week, which has caused some little confusion. The above is the correct address.—*J. H.*

HOT-WATER PIPES *versus* FLUES.

IN describing, a few weeks ago, the gardens at Ravensworth Castle, Mr. Robson remarked on the advantages of flues over a hot-water apparatus there and at other places similarly situated as regards coal. I have looked through the succeeding Numbers of *THE JOURNAL OF HORTICULTURE*, expecting some hot-house builder or hot-water apparatus manufacturer would have remarked on the alleged advantages, and in opposition stated some of the advantages of an efficient hot-water apparatus. But, perhaps, they have been deterred from doing so by the obviousness of the advantages, and not from any delicate feeling of seeming interest in the matter.

With all due deference to Mr. Robson's better judgment, I am still of opinion that even with coal at 4s. per ton in large places, hot water is the cheaper in the end. It not only reduces the labour in attending to the fires, which is no inconsiderable item if two or three men are required for the purpose, but it also reduces the haulage; and these advantages together would, I believe, do more than cover the interest on the outlay upon an efficient economically-constructed hot-water apparatus.

I quite agree with Mr. Robson in the greater freedom from

"blacks," from a long horizontal flue than the short vertical ones usually erected over boilers; but I think that evil is counter-balanced by the perfect freedom in-doors of hot water from all noxious gases which sometimes escape from flues, and the ab-

sence of the dust and mess occasioned by opening them in plant-houses for the purpose of removing the soot, &c.

Mr. Robson, I am sure, will courteously receive my doubts of the economy of flues.—W. CRAW, *Enville*.

ALCOVE-AVIARIES AND BOWERS.

THE grand general principle of propriety in garden decorations is, that they should never be objectless; and this, with the selection of sites, which should be so felicitously chosen as to give to each structure the appearance of being in a position, as

it were, predestined for it, forms the fundamental law of the code of landscape-gardening.

The accompanying design for an alcove-aviary is intended to occupy a position not distant from the residence, and yet con-

AN ALCOVE-AVIARY.

cealed from it. It should form a point of attraction capable of inducing frequent visits, by its convenient proximity, and yet convey to the spectator an impression of agreeable surprise every time it is approached. These conditions are not difficult of fulfilment. The readiest mode would be the following:—Let us suppose a side garden-door of a country house (not the principal entrance) opening upon a small lawn enriched by geometrical flower-beds, or a rosery, through the midst of which a dry broad path leads towards the shrubbery, which is entered by a winding walk, at a given point of which, about half way through, the visitor is introduced by a sudden turn to an open space of long, oval form, running longwise in the direction of south-east to north-west. This space should be bordered with a neat but somewhat bold and massive cement coping, which would form a support of congenial character to the pedestals and vases which are intended to stand on each side of the entrance, and, at distances, all round. The entrance should be at the south-eastern end of the oval, opposite to the alcove-aviary, which would thus have a favourable aspect, securing the

early morning sun, so essential to birds, especially in a state of comparative confinement. Both the entrance and the way out should be concealed by well-designed windings.

I propose that the front and exterior sides of those portions of the structure devoted to the aviary should be of one piece of strong glass, which would enable birds to be seen without the disagreeable intervention of wirework, and at the same time form a protection from cold winds and beating rain, highly important to the healthy keeping of the birds. On the interior side of each compartment of the aviary, I would have wirework only, as open as the size of the birds might render advisable. This, with the addition of proper ventilation planned under the thatch, would admit a sufficient quantity of air, and would place the birds in more open and immediate intercourse with the visitors, snugly seated within the shade of the alcove, and watching the varying play of sunshine upon the plumage of the moving birds, or renewing the food and water of the inhabitants of the aviary, which, it is scarcely necessary to state, should be done every day at least once, but if twice so much the better. For

these purposes, it is of course necessary that a wirework door, large enough for a person to enter, should be framed into the interior wirework.

It will be seen by the design that a more decorative style of rustic-work is suggested than that usually employed—a branch of garden decoration on which I intend to offer some advice, accompanied by designs, on another occasion.

Rustic-work of this character, if found impracticable by the usual mode—that of unbarked branches judiciously interlaced—should be roughly carved in wood, and varnished with transparent but deep brown varnish; or might be modelled, and then cast in cement, or even in iron; and I wonder much that low fences, &c., have not been cast in iron in that style. The edge of the roof is surmounted by smaller rustic tracing of a similar character. This alcove-aviary should be well backed-up by thick-growing trees of considerable size, and the plantation should be of sufficient depth to prevent it being seen through, or the effect of a dark background to the structure would be destroyed, and the spell of seclusion—the great charm of the scene—would be broken.

An additional interest might be imparted to this secluded spot by the introduction of a large but excessively simple tazza, containing gold fish; into this a gently bubbling fountain should convey a continual supply of fresh water. This tazza should be almost of the dimensions of a miniature pond or basin, while its slight elevation on a low stand, as designed, would give it a novel and architectural character in keeping with the other dressings of the scene. The small fountain in the centre might be made to issue from an opening of miniature rocks, raised slightly above the level of the water, and covered with water-loving Ferns and Mosses. But the exterior of the tazza should be kept freshly cleaned or painted; for wherever animal life, in whatever form, is the object to be petted and cared for, an appearance of daily attention and perfect order and cleanliness are the most agreeable adjuncts to all arrangements for the purpose. The stand of the tazza is intended to be surrounded at some little distance with a low cement coping, within which some low-growing profusely-flowered plant is intended to grow (such as Thrift at some seasons, double Daisies at another, or annual dwarf Lobelia at another), which would partially break the formality of the coping, without destroying its symmetrical effect.

An aviary and alcove of this kind might be approached from the house by a covered path if thought advisable, in which case the entrance from such a path should be from the back, so as not to disfigure the open approach; and in that case a door in the back of the alcove should lead to the covered path, which might pass through without interference with the close shrubbery, which should effectually shroud the back of the structure.—H. N. HUMPHREYS.

On the subject of Bowers, we append the following hints and sketches supplied by another correspondent:—

It sometimes happens, when trees are cut down a few inches from the ground, that they send up shoots all round the stump. These shoots grow to a greater or less height, according to circumstances, and in some cases even attain a size little inferior to the original tree. It is difficult to prevent these shoots pushing up from a tree-stump, which thus often becomes a source of annoyance on a lawn or pleasure ground, while the labour of uprooting it is grudged. One mode of overcoming this evil, or rather of converting an object of annoyance into an

Fig. 1.—Tree-stump preparing for a Bower.

object of utility and ornament, is illustrated by the following sketches. Fig. 1 shows the stump of a tree (Ash) with the young

branches grown up round it; and fig. 2 illustrates the fashion in which these branches may be made to form an elegant canopy to one of the most natural of rustic seats—the stump of the

Fig. 2.—The same more advanced.

tree; which may, however, be provided with a soft cushion if required. The branches need simply to be tied together by means of wire; and if a few plants of Ivy and Brier, with one or two of the more choice climbing Roses are planted around the base, the whole would soon become very compact and beautiful. The wires should not be tied tightly, lest they should cut the branches in the course of time; and perhaps, for this reason, ordinary string-ties would be preferable.—DELTA.

MUST SEA-KALE BE OFTEN RENEWED?

YOUR correspondent Mr. Knight, in No. 89, page 716, says the Globe Artichoke, like Sea-kale, should never be allowed to remain in a garden after one or two years if grown for profit. If that be the case I am sadly out of the rule, for I have some Sea-kale that has been in the same bed for the last ten years, and it still proves very profitable; but then I do not force the plants too severely, nor cut from them two or three times in a season.

Sea-kale, like an animal, if hard worked and badly fed will soon be exhausted.

My Sea-kale is just coming on. Before I cover-up the plants I always let them have a drinking carouse with their friends, the liquid cans, merely to wish each many happy returns of the season. Also about June I allow them to show off their new and blooming foliage.

I think if the Sea-kale plants are properly treated they will last much longer than our friend Mr. Knight has been led to believe.—P. M.

EARLY GRAPES.

IN a letter from "J. E. F., *Knowsley Hall*," in No. 88 of this Journal, he disputes Mr. Thomson, of Dalkeith, being the first person who produced early Grapes on the 1st of January. In reply I beg to inform "J. E. F." that Mr. Thomson was the first ever reported to have shown early Grapes on the 1st of January, which he did on the 1st of January, 1861, and on the 1st of January, 1862. The only early Grapes reported to have been shown were grown by myself. There were also one or two other samples exhibited about the middle of January; and if "J. E. F.'s" Grapes were ready by the 1st of January, why did he not send them for inspection until the 10th of February, 1862?—JAMES FOWLER, *Harewood Gardens*.

PROTECT THE GLOBE ARTICHOKE.

ABOUT fifteen years ago we had a very severe winter. I was but a lad, but well remember in the garden where I was this now much-talked-of Artichoke was not protected, consequently the plants were all killed. It is true we do not very often have such severe winters, but there was in 1860-1.

I have grown them in my present situation, and probably taken more care of them than some folks, for I always protect them, and, therefore, seldom lose any; but in the year 1860 I lost several plants notwithstanding the protection.

Your correspondent, Mr. Henry Knight, in No. 89, page 716, thinks if the plants are but one or two years old they will stand the frost the better. Now, I have no faith in that; for in 1860, when I lost most plants, they were all young, and not one of the old plants that perished; but even these came up weakly, and proved of little service. They all received the same protection, which was coal ashes heaped up round them from 9 inches to a foot deep. If you will be always safe I say, as does your correspondent "J. H. M.," Protect them.—H. G., *Stroudwater, Gloucestershire.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHEREVER the soil will admit of being moved with advantage, let every vacant piece of ground be trenched or deeply dug and be left in ridges. Keep the Broccoli, Celery, and Spinach free from dead leaves. Carrots, where young ones are wanted early, prepare a slight hotbed for the purpose, cover it with leaf mould to the depth of 6 or 8 inches, in which sow the seed. A little Radish seed may be scattered on the bed at the same time, but the roots must be drawn in a young state. Cucumbers, prepare dung for the main early bed, making a small seed-bed for raising the plants. Lettuce, where there is a scarcity of autumn-sown, sow on a slight hotbed or in boxes in a forcing-house to be afterwards pricked into a frame. Sea-kale, as that which was covered first is cut, remove the pots to that portion which has hitherto had no covering, so as to keep up a succession. The dung and leaves which have been previously used will serve the purpose again if a little fresh be added.

FLOWER GARDEN.

The very common but bad practice of digging shrubberies is generally one of the principal occupations at this season. It is to be regretted that such is the case, as the operation is highly injurious to the trees and shrubs, in consequence of destroying a large portion of their most valuable roots. The digging of shrubberies for two or three years after they are planted, where there is no danger of touching the roots, is no doubt highly beneficial to the plants, but after that time nothing should be done to disturb the roots near the surface, as the health and vigour of the plants in many cases depend almost entirely on them. Where alterations are contemplated—such as making new walks, new flower-beds, or renewing the soil in old ones, these should be forwarded whenever the weather will permit. Holes for planting choice or new shrubs or trees may also be prepared, by removing the bad soil and replacing it by a compost suitable to the plants; and even when trees are planted and not growing well, the soil may be carefully removed from the roots and replaced by better material.

FRUIT GARDEN.

Proceed with pruning, and protect newly-planted trees by mulching their roots. Strawberries in pots, put a quantity of these in heat, according to the stock and demand, every fortnight. Keep them near the glass, and begin with a temperature of 45° to 50° at night, increasing it to 55° by the time they begin to truss-up. In all stages of growth the Strawberry must be well supplied with fresh air, and a damp stagnant air is certain ruin thus early, when in bloom especially.

STOVE.

The temperature of this house should not exceed 60° now by fire heat, and a fall of 10° may be allowed at night in very cold weather. Although all plants now at rest should be kept comparatively dry, they will require to be looked over occasionally to see that they do not suffer for want of water, especially those nearest the pipes or flues. Orchids may be potted, tied up to logs, or fitted into wire-baskets at a time when but little can be done out of doors, but they need not be watered or induced to grow for some time.

GREENHOUSE AND CONSERVATORY.

About 40° is a good temperature for these houses when not attached to sitting-rooms, and when only used for the purpose of wintering large specimens without plants in blossom; but where a supply of stove plants in bloom is kept up from a forcing-pit, which is necessary to every good conservatory in winter, the best

heat is 45°. Cinerarias, which are great favourites, are thirsty plants, and will require to be carefully attended to with water. If Camellias are not regularly supplied with soft but not too cold water the buds will drop; if too much is given, frequently that will cause them to drop too. Thin the flower-buds if crowded. Never give heat to Heaths as long as frost can be kept out by coverings. A few degrees of frost will never injure Cape Heaths, whereas fires are their ruin. Let the air blow upon them on all favourable occasions. So with the entire class of New Holland plants. Chrysanthemums, now done blooming, protect from severe frost. If the soil of any plant is sodden with water it should be turned out of the pot and the drainage examined, and no more to be given until it becomes dry. If a plant droops and the soil on the surface is damp, by turning the ball out of the pot it will be seen whether the whole or only a portion of the soil is wet, as sometimes when wet soil is used and fresh potted, it dries and shrinks from the sides of the pot, and when water is applied it runs down and moistens the outside without penetrating the ball.

FORCING-PIT.

The plants here now require constant attention. Keep them neatly tied-up as they grow, and once or twice a-day look over them with the water-pot. Remove them as they open, and bring in a succession. Neapolitan Violets may be brought in to force now. Forcing Roses must be looked over frequently, or the "worm i' the bud" will soon destroy the cultivator's hopes.

PITS AND FRAMES.

Keep the plants in these structures as hardy as possible by fully exposing them in mild weather. Do not give them any more water than is absolutely necessary, but when it is given all the soil in the pot should be wetted. Clear the surface of the soil from moss and weeds, remove all decaying leaves, and preserve the atmosphere in as healthy a state as possible.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

LOOKED over Broccoli, and bent a few leaves over those heading, to protect them alike from much wet and any sudden frost that may come. Took-up a few rather forward, and put them under a thatched shed; find they will keep longer thus than if planted in a pit with glass covering. Some years ago I detailed how Mr. Crockett, gardener at Raith in Fifeshire, kept Cauliflowers all the winter on the floor of a shed with a small window to the north, by merely cutting the heads when about half-grown, with a foot or so of stem, removing all the leaves, and fastening the stems firmly in light sandy soil, so that the heads did not touch each other. I can vouch for this being one of the best and easiest modes for securing a winter supply. The heads when cut were thrown into a pail of cold water for a few hours before sending them to the kitchen. I meant to do something of this kind with a bank of late Cauliflower, but was unable; for, owing to the mildness of the weather late in autumn, the whole plantation, from not being looked at for a few days, got too forward for managing this way, and was, therefore, used for common purposes. It is no use trying this, or, indeed, hardly any other method, of thus saving Broccoli and Cauliflower, except the heads are firm and not too large. I may mention, in the case of those coming on out of doors, that in addition to bending a leaf or two over the head, it is advisable to have a bundle of old hay or oat-straw, just to stick a small handful over each head in a sudden frost. Stirred the ground among young Lettuces, Cauliflowers, Cabbages, and Radishes in frames, thinning the latter also to give them room to grow. Among these a few Carrots and Lettuces were sown. Prepared what little fermenting material could be had for beds of Carrots and Potatoes; a Carrot-bed being one of the most profitable things when slightly forced that I know, and especially if left pretty thick, so that the first gatherings act in the way of thinnings. Sowed Cucumber seed in a sweet small hotbed almost wholly of leaves, with a good dusting of lime on the surface layer to settle worms and snails, sowing the seeds in large 60-pots, and then placing the small pot in the bottom of a 32-pot, and a square of glass over the latter, and a weight on the glass to prevent a mouse getting at the seeds. The glass will also permit the plants to grow into the rough leaf before shifting, and after that mice in general will not touch them. Sowed some Tom Thumb Peas about six seeds in 24-sized pots, and also some in

60's, to be again repotted, and put them in a frame to bring them on a little, so that they can be fruited in pots under protection. Swept over Mushroom-beds, having great plenty of all sizes; the chief complaint is that they are individually rather thick. In the last earthed bed, the man who manages the beds left a piece of the earthing rough and unbeaten. Altogether the earth was rather too wet, and I was a little doubtful about it, and on that account covered it with straw and hay, which drew up the damp, and were removed as soon as dampish, and dry substituted. The whole bed is now like a sheet; but the little fact I wish to chronicle is that the yard or so, with the earth left loose and unbeaten, came the first into bearing, and very strong, which the workman ascribed to the looseness of the soil, and I to the fact that that part was close to a boiler which was frequently used; however, there may be a little in both reasons. The chief object in beating these shallow beds firm, and beating the one-and-a-half to two-inch covering of earth also firm, is to secure strong short-legged Mushrooms, and for the ease with which a bed can be swept with a hair broom when from coverings or other causes the spawn would be inclined to run along the bed instead of throwing-up the Mushroomis. From what I have several times observed, however, did I want Mushrooms in a hurry—say three weeks or four weeks after spawning, I would cover with about an inch of soil, and leave it rather loose and rough. I should not expect such a bed to last long, but it would be earlier than one well beaten and deeply covered. From six to seven weeks I should expect to pass before I gathered from the latter.

FRUIT GARDEN.

Here the work has been much the same as in previous weeks. Damping the Vines in a small pit, temperature averaging 55°; putting a few hot leaves on viney-border, and the stubble that was there before over them, making about 14 inches in all. Looking over Grapes in late house, and find the Hamburgs are just getting too ripe and beginning to go here and there. West's St. Peter's and Muscats still very good and likely to keep much longer than we can let them. There is a fine idea in Mr. Thomson's book on the Vine with respect to such houses in which it is desirable to keep Grapes late, and yet have them moderately early, which, though not new to me, as I followed it out twenty-five years ago in a large house from which Grapes were cut from June to Christmas, has yet been little referred to, if at all, in any work on gardening—that is, to go over now the shoots on which the bunches are hanging, and pick out all the buds except those wanted to break next season for bearing-shoots. By this means bunches may hang on the Vines—and better there than anywhere else, so long as the house is kept dry—until the sap begins to rise, and then, when the bunches are cut, all the snags may remain until the fresh shoots from the buds left are in leaf, when all may be cleared away without bleeding or any other injury to the Vine. This will just meet the difficulty of "JUVENIS," who has some Black Grapes that he thinks he could keep until the end of February, only he must start the house by the end of February. He may prune now in the regular way all wood where there is no fruit, and disbud all the rest of the shoots, except those at the base of the shoots, or where otherwise wanted. If plants requiring much water must be put into such houses, the bunches should be put in glazed bags loosely to exclude damp; or the shoot with the bunch may be cut off, the end inserted into a Beetroot, and the bunches suspended in a dry room, as Mr. Thomson also recommends. In looking over some Peach trees in pots found two or three pretty well clustered with the black beetle, though the plants had been moderately smoked with sulphur, and the trees had been well syringed with soap water at about 170°; so it shows how hard this gentleman is to kill. The worst of it is they seem to deposit their eggs in the soil in myriads. The trees already not so treated will be well scrubbed with soap and water, and then painted with clay and sulphur and a little Gishurst. Those so done a month ago give as yet no sign of insects of any kinds, and when such painting is resorted to I think it should be done a considerable time before the buds begin to swell. Looked over Strawberries, and gave a little water when necessary. It is of little use hurrying them on in such weather unless when wanted early.

CONSERVATORY.

Removed the most of the Chrysanthemums, placed the pots in an earth-pit, covering thinly with tree leaves, where they may remain until we want the pots, when they will be turned out.

Those who want large plants next autumn should now be getting their suckers in; and the quickest way, if not for exhibiting as single plants, is to put three suckers in a pot. Filled-up with Geraniums, Calceolarias, Cinerarias, and formed edgings of Variegated Geraniums. All hardwooded plants should now have plenty of air, but if very moist or frosty it should not beat on them directly. In watering, great care should be taken not to overwater, and, what is of more consequence, not to pour water on the collar of the plant, but rather near the sides of the pot, allowing the water to flood the pot all over. The pouring the water on the stem, so as to make a depression there, more than anything causes gangrene in such stems, and sends many a plant to its last resting-place in the rubbish-heap that otherwise might have lived and been beautiful for years. Plants, taken from forcing-pits and houses—as bulbs, Roses, Diehytras, shrubs, &c.—should be hardened with more air and a cool standing-place before being taken to a greenhouse or a conservatory.

PITS AND FRAMES.

Examined all these again in this dull weather to remove all trace of damped leaves, which so soon taint the air at this season; and when the soil in cutting-boxes was at all damp, not only stirred the surface with a stick, but threw a little very dry soil over the surface. Of course small plants standing thickly together will require more looking after than those that have a little pot each to themselves. I am now getting soil nicely dried over furnaces and in sheds to mix with what is already dry enough in stacks for potting-off great numbers of such things as Variegated Geraniums into the smallest pots, which by the time the roots have filled the pots will be again emptied; the plants going into beds or boxes, to be protected when necessary until the third week in May. The great difficulty now will be to find room for and get forward the numbers that will be required. A little carelessness about the new year, either as respects damp, watering, or insects, will often render abortive all the care of young stock since September. Many fine batches of Verbenas last year on Christmas-day could hardly be said to see the 1st of February. Thrips and other evils did for them as soon as the sun gained a little strength.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

COCOA-NUT REFUSE (*A Regular Subscriber*).—The dust of the sample you sent is the portion used in forming a compost, or as a manure. The fibres must all be taken away, but they would do instead of moss for covering the drainage of your pots, and for the surface of Strawberry-beds.

LYME (*An Ignoramus*).—It absorbs carbonic acid gas from the air if long exposed to it, and combining with the acid thus absorbed is converted into chalk, or carbonate of lime. In very few instances can lime be of use in garden soils. It may be mixed with advantage with peat or other soils overcharged with vegetable remains.

AZALEA LEAVES FALLING (*Rebecca*).—It is as natural for the Azalea, unless kept extra warm in winter, to shed a few of its leaves, as it is for an Oak or a Beech to cast its leaves. This interferes little with the beauty of the plant at flowering time, as, with the expanding of the flower-buds, fresh foliage also comes. Your leaves have, however, something more than age to make them discoloured, as, though we found no thrips, we found their signs in plenty. If the plants are large, the best remedy is to smoke them with shag tobacco two or three times, at an interval of three or four days; keep them rather shaded, and take the plants individually outside; lay each upon a cloth on its broadside, and syringe thoroughly round and round with clear water at a temperature of 120°. Let as little of the syringing as possible touch the soil in the pot. If the plants are small, the most effectual mode would be to dip the head of the plant in size or gum water, just strong enough when cool to show a little adhesiveness between the thumb and finger. Keep in the shade two or three days, then draw the fingers rapidly through the leaves and shoots, and syringe thoroughly with water at 130°.

BOOKS ON BOTANY (*Subscriber at Wigan*).—Henfrey's "Rudiments of Botany," and Smith's "Introduction to Botany," edited by Macgillivray.

PLANTS FOR BACK OF A CONSERVATORY (T. B. C.).—As you seem to have quite enough of Vines in front, the best thing you could do with the back wall would be to plant it with Camellias and Oranges. Some years ago we described how such a wall was beautifully clothed in a vinery and Peach-house at Tingirth. If you planted Vines at the back and trained-down, there would be no doubt of their succeeding beneath the glass; but with the other Vines, and the stage in the centre, neither they nor anything else would do any good against the back wall itself. With that stage, even Oranges and Camellias would thrive only in proportion as the Vines were kept pretty close to the rafters.

PEACH TREES IN BAD ORDER (W. Nowlan).—We fear your trees, which you say have not made more than 2 or 3 inches of wood the past season, are past all remedy, and if so, removing them and planting others in fresh maiden loam is the best thing to do; but if they are young trees, and not otherwise diseased or deformed, the free and judicious use of the knife may restore them, taking care to leave what young wood you do retain at its full length. If, however, these short shoots have not ripened well, there must be something wrong with the border, and if it want draining let that be done at once. Report to us the result, and attend to some other instructions that will be given from time to time on the Peach and other trees.

SCARLET GERANIUMS IN BOXES (A. P. S.).—If you have space at command in spring, it would certainly be better to pot these singly in small pots; but, as generally happens, every inch of glass is full to overflowing at that time, and it is hopeless to expect a pot for every plant. Mr. Fish has, on former occasions, explained how he deals with them, and Mr. Robson has also promised to do so. The latter, to whom we have referred your inquiry about putting the cuttings into the boxes at once, instead of first striking them in the open ground, says there is no particular disadvantage either way; but he prefers taking-up and replanting, as greater regularity can be given to the mass in the box, as by having them put into the box at first, the loss of one or two cuttings in a particular place causes a gap. Mr. Robson says he often enough keeps Variegated Alyssum, Lobelia, Tropæolum, and other plants in boxes; but for the spring-forcing of these in hotbeds broad pans are better, as they suffer less by being plunged in the sawdust or other damp material, otherwise the boxes are quite as good and more convenient in handling, &c. Verbenas are better kept in winter in larger pots, as the spring growth is of most consequence in them.

WHITE SCALE ON PINE APPLES (J. B.).—Your dusting the roots of Pine-Apple plants with soot, will not kill the white scale upon them. Washing the whole plant, roots and altogether, with soap water holding a little size in solution, and at a temperature of about 140°, letting the plants drain, and in a day or two swinging them through clean water at about 120°, would be more effectual. The best plan of all would be to have a bed made from 30 to 36 inches deep of fresh horse-droppings; make a wicker bed over it, on that place all the Pine plants, and shut-up close for forty-eight hours if the atmospheric heat is not above 100°.

THRIPS ON CUCUMBER PLANTS (E. C. Q.).—If the plants are in a house, that you can examine the under side of the leaves, there is nothing so effectual as the Weaver remedy—that is, "Catch and kill them;" thus, have a basin, with a little water, and a small sponge wet, which dab on every jumper you see. We prefer doing it with the finger ourselves. You can use syringing very little at this season. Next to the above, the best remedy is smoking two nights running with the best shag tobacco. If that does not settle them, break and bruise a bushel of laurel leaves, and spread them out in the place; and if that does not do, smoke again. Be sure the smoke is cool. The mischief is that, if you have allowed the thrips to get a-head, you may kill all alive in a couple of smokings, and in a few days you will have fresh generations of them to tease you. If taken in time, there is nothing like a quick eye and a nimble finger.

BURNING SULPHUR IN A VINERY (A. Kentish Amateur).—Of course you do not mean to burn sulphur in your vinery with plants in it, to kill thrips and red spider, because it would kill every green plant. If the Vine wood is well ripened, and you took every other plant out of the house, you might then burn half a pound of sulphur mixed with sawdust in such a house, doing it before dark in the evening, and keeping the house shut the following day if dull, but giving air if sunny; then scrub the house, and do as detailed in "Doings of the Last Week" a fortnight ago. A little care and trouble now may save you much annoyance in summer. The *Tradescantia zebrina* has white bars along the purplish-like leaf.

HEATING A GREENHOUSE AND FRAMES (S. Taylor).—There is nothing to prevent your plan answering, only when you work both greenhouse and frames, it will be necessary to regulate the draught with the damper below the coil, as the heat will be more apt to ascend there than pass along the flue. A little regulating will make that all right. If your furnace-bars could be sunk a little more—say 6 or 8 inches, it would be as well; but as they are you will manage.

BOUQUET FRAMES.—W. H. M. asks, "Is there any place in London where wire frames for making hand-bouquets, as described in No. 662, Vol. XXVI., page 172, can be bought?" Can any of our readers give the desired information?

FORCING PELARGONIUMS (Hortus).—*Alba multiflora*, Gauntlet, Crimson King, Dennis's Alma, and Blancheffeur will answer your purpose for early spring flowers.

CEMENT INSTEAD OF PUTTY (Idem).—Portland cement instead of putty, for glazing an old, rickety, leaky greenhouse, and with waterlogged sash-bars, is a very odd idea and a very unlikely thing to answer; but as we have never tried it, and never heard of such a thing, we would recommend you to try the original idea yourself, and let the world know how it answers. But we can confirm your apprehension, and say from experience that paint and putty laid on wood that is green, damp, or wet, is a sure method to destroy such woodwork.

RAIN WATER (Inquirer).—If the thatched shed is very old, the water will be apt to become thick and smell disagreeably; but you could remedy this by causing it to pass first through a small barrel with a lot of charcoal and gravel in it. There will be no danger from that source of red spider, &c.

TOBACCO REQUIRED FOR FUMIGATING (Idem).—For a house 20 feet by 2 feet, a quarter of a pound of shag tobacco would be enough at a time, urned slowly, and the smoke emitted cool by passing through a covering of damp moss.

COTTAGE GARDENERS' DICTIONARY (M. A.).—It contains both the botanical and English names of plants.

CHRYSANTHEMUMS FOR EXHIBITION (Young Gardener).—You want to exhibit next Martinmas, without knowing when to make the cuttings—on the first of the new year; and then you want to know the best twenty-four kinds for showing. There are hardly twelve kinds of good habit to make specimens of that would carry a prize in these days.

ICE-KEEPING (An Eleven-years Subscriber).—We think you have overdone the ventilating. If twenty loads fill the place, the ice-well must be small, and extra care requisite. The water at the bottom, if it did stay there would melt the ice if the vapour arising from it rose up. The ventilation has been extreme. We would have kept the surface of the ice covered, and had a six-inch opening in the door, and a three-inch opening in the dome. Mr. Fish uses no straw when he does not ventilate. If he ventilates moderately he prefers the surface of the ice to be covered with straw.

PROTECTION FOR FRUIT TREES (Museum).—Thin tiffany or Nottingham netting still thinner is the best protection for fruit trees yet out, where the covering is to remain night and day, and where the frosts in general are not severe. Neither of them will be sufficient if the blossom should encounter a frost of 10° or so. Their chief value is, that through them the openings are small, and the trees are kept dry, rains trickling down instead of going through them. Numerous temporary expedients may be resorted to; but the most lasting and every way the best means yet out, if labour is not grudged, are coverings of strong calico sheeting, put on so as to be easily moved by pulleys or rings. These should be put on as soon as the buds begin to swell, kept on on sunny days to retard the blossom, and removed on dull cold days for the same purpose; but taken off after the blossoms open in fine mild days, and replaced at night. We have known such covers put away dry, last a great many years, and there is nothing so good yet that we know of. The first expense is the only objection, especially at present, but even now they would be cheaper in the end than most of the things so highly recommended.

GISHURST AND OTHER INSECT-DESTROYING COMPOUNDS (Idem).—We believe that Gishurst compound is good judiciously used, and so are Farmer's, &c., but no preparation will work such wonders as the advertisements generally state. A little allowance must be made in these matters for the zeal and enthusiasm of the inventor, and the result often is, that after each in turn being a great favourite for a time, the gardener at last often turns back to old-fashioned methods, which on the whole he finds quite as efficacious. Soap and sulphur, and something of the nature of tobacco, are the chief materials in most of these wash mixtures, and it is often a great advantage to have them in a concentrated form ready for immediate use.

NAME OF FERN (A Constant Reader).—It is *Pteris serrulata*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

PAST AND FUTURE.

OUR task is a sort of "Montagne Russe." The impetus derived from the descent of 1862 should carry us up the ascent of 1863. We are thankful it is so, and that on our first appearance in the new year we can hail our friends cheerily, thanking them for that support which has made our task an easy one, and which has given a charm to our daily pursuit. We are glad to avow our grateful sense of the mercy that has enabled us to pen another address to our many readers.

The year that has just closed has been a prosperous and pleasant one for those concerned in the pursuit of which we treat. The "happy medium" has been its characteristic. We have had no "sensation headings" of success or failure. We have kept on the even tenor of our way because things have been smooth with us and our pursuits. While we are very thankful for it, we can but feel what a damper it puts on verbosity. "Thank you" will express the gratitude of twelve months. The slightest complaint will cover sheets of paper, or feed eloquence for an hour. We are almost disposed to wish we had a little grievance. We know with what feelings we laid down the "History of England" when, at the conclusion of one of the chapters in the reign of George III., we read—"England had no peace at home, and little glory abroad." We knit our brows and sat moodily down in an easy chair, and we brooded from daylight to dusk, and from dusk to dark, and still thought "no peace and little glory." If we had read "peace and glory," we should have had little or no interest in it. Only imagine the difference between lecturing the labourer on the blessings of his position, on 9s. per week wherewith to keep a wife and seven children, one deaf and dumb, and two under three years of age; and the poor "ticket-of-leave" who has yet three to serve of the eighteen months which will entitle him to liberty, although sentenced to ten years penal servitude!

What a dull audience while we explained to the labourers the advantages of their position and the luxuries within their reach! What startling attention from the poor convicts while we told them a large part of the country sympathised with them—that it was enough to deprive them of liberty, without serving their mutton so cold that the fat swam on the gravy—and that all society wanted was to reclaim, not to punish them!!

Reports and reviews are like portraits. The even line of beauty is hard to catch, and the likeness is difficult; but in a face with a marked feature—a nose like a knocker for instance, the artist has something to lay hold of.

Revenons à nos Dorkings. We have not to note any remarkable change in weight. They are nearly as large as they can be, they have been shown in better condition and feather than at any previous time, and they have held the position gained years ago by their own merits.

Cochin-Chinas have decidedly improved so far as the Buffs are concerned. The Whites hardly remain where they were; and those rank imposters, the Blacks, have disappeared.

Spanish have not held their own in 1862. When Mr. Davies gave them up, Mr. Rake took his place. He has not shown this year, and he is missed. Who will come to the rescue?

Hamburgs have been most excellent except the Silver-pencilled. There is no reason why these latter should fall off because Mr. Archer proved they might be produced perfect in every particular.

Polands are improving in every way, and we have seen birds this year equal to anything we ever saw.

It is needless to eulogise the Game—they are always perfect. In this breed Mr. Archer has done as he did in the Pencilled Hamburgs. He is always successful. The same may be said of many other exhibitors in these classes, the Hon. W. W. Vernon for instance; and it goes far to prove, that spite of all "wise saws" to the contrary, mortals may command success.

Brahma Pootras are appreciated, and it is only here and there a caviller can be found. We must rank them with those who believe that donkeys are immortal, and that post boys never die. Not only are the merits of these birds admitted, but their points and plumage are so equally. The beauty, uniformity, and numbers of their classes will prove it.

Malays do not grow in numbers; they are perfect in quality, but there seems a limit to their entries.

Bantams are what they always were—favourites with the public. We suppose on the same principle, that if two boys of unequal size are fighting, nine out of ten side with the smaller. The Game Bantams are becoming one of the large classes. The Blacks and Whites have their defined points. The Sebrights do not increase in numbers, but they have been perfect in size, carriage and feather.

Geese are still onwards—a truly marvellous pen at Birmingham, three white birds weighing $76\frac{1}{2}$ lbs. Geese of 20 lbs. are common, and Mr. Fowler has a habit of showing three Grey birds that weigh 73 lbs.

Aylesbury Ducks hold themselves excluded if they do not weigh 7 lbs. each, and the Rouen tread on their heels. This latter class is marvellously increased, and bids fair to be the largest of all Duck classes. The birds shown are also perfect in colour and bill. The experiment of a class for Black Ducks has proved itself a success.

Turkeys remain excellent in weight, but they do not increase in entries.

We have to notice the advent of a new breed in numbers that, with a small increase, will demand a separate class. We allude to the Crève Cœurs. Mr. Wakefield, of Dorking notoriety, has been very successful in this class. Report speaks highly of them as table fowls. The Black Hamburgs were also strong in numbers and quality at Birmingham.

Shows have been numerous and well attended. Sales have, in many instances, been very large. Exhibitions are on the increase in Scotland, and capital birds are shown.

As a market commodity, and as an article of food, poultry has been unusually scarce and dear throughout the year. We still lack statistics on the subject. They would startle the most supine. During the war at the beginning of this century, a meeting of coach-proprietors and of those who horsed coaches, was held at Stratford, to consider the price of oats. Among those who were summoned came a stranger. Who was he? He modestly said he was a goose-feeder. He was pooh-poohed and laughed at, till he proved his consumption, which was twice as great as any of the sufferers present. It would be the same now, if some of those who fancy they represent important interests could see poultry-returns.

We have gone on glibly. We have had only to speak of generalities and of others. There is no difficulty in that; but now we must speak somewhat of ourselves.

Friends, correspondents, contributors, we thank you. It is much to say that all has gone on harmoniously for twelve months. We can say so, and when such is the case something is due to every one. We gratefully acknowledge it, and to such cheerful co-operation we attribute in a measure the success that attends us. We have no new profession of faith to make.

We appeal to the past, and assure our readers that as we have been so we will try to be.

Tied to no party, wedded to no opinion, we endeavour to hold an even balance, and to be the impartial record of all events that pertain to our columns. They are open to all, provided nothing offensive or injurious be found in the contributions. We can honestly say we have not knowingly printed one word with a view to cause pain: if we have done so unwittingly we are sorry for it. We would stand well with all, and in our mind's eye seeing all our friends, we desire to wish them heartily

A HAPPY NEW YEAR.

MANCHESTER POULTRY EXHIBITION.

ALTHOUGH the shadows of the last evening of the year 1862 are fast brooding around us as we commence our remarks on this interesting Meeting, it really appears but, as it were, yesterday when we stated that the inaugural meeting of this Society had taken place in the Belle Vue Zoological Gardens, among the many festivities provided for the public by the spirited proprietor, Mr. Jennison, last Christmas. Last year the Show was well supported on all hands; and the congratulations were universal, that although poultry shows in Manchester had unfortunately, from some cause or other, hitherto proved altogether a failure, under an improved management an entirely reversed issue was effected. The prizes of 1861 were in the aggregate £500, and the entries amounted to 565; the value of the premiums being somewhat dependant on the entry money received from the exhibitors. The worth of the prizes compared to the number of competitors being far greater than in any case that had preceded it, combined with the most prompt and scrupulous payment to the winners, augured well for future meetings; still there are always parties to be found who profess to see a cloud, however clear the horizon.

Acting on this grumbling anticipation of future ill luck, there were to be found those who, not being themselves successful in their own previous efforts, hesitated not to roundly affirm, that even apparently successful as everything then appeared, another year would prove its want of vitality, and that the "new Show" would soon follow in the footsteps of its predecessors. The dauntless proprietor of Belle Vue Gardens, however, was not to be turned from an object that had previously received his well-matured attention in all points: consequently, a far more commendous prize list was issued in connection with the present Meeting; and the entries it this year called forth were 1288, being very considerably beyond the double of last year, and carrying with them an appropriation of prizes to the tune of £800. The above statistics refer alike to both the poultry and the dogs, the Exhibition being a combination of the two, thus affording attractions to the lovers of either the one or the other. We rejoice that so well merited a result has ensued; for none could strive more energetically than did the whole of the Messrs. Jennisons to fulfil their duties with credit to the Show, tempered with an amount of civility to every inquirer the most praiseworthy. Each individual had his allotted task to perform, each stood well to his post, and the sequel proved that everything was carried out without mistake or misapprehension of any kind. The unbroken order, promptitude of action, and general management of the Exhibition thus became the subject of universal admiration.

A few of the most important points of excellence we must briefly allude to. Perhaps there is not to be found a building more excellently fitted for the carrying-out of such a Show than the great Music Hall of the Belle Vue Gardens. Every pen of poultry was placed at a proper height, and in a single tier. The light was universally good, so much so that the most anxious exhibitor would scarcely have troubled himself to make a selection for his birds, even had the opportunity been granted him. This is a boon to an exhibitor that cannot be spoken of too favourably. The scrupulous cleanliness of the pens and kind attention to the birds exhibited could not possibly have been surpassed.

This brings us more especially to the matter of the pens themselves. They were the most convenient we have met with, being both airy and sufficiently large for even a group of Cochins, Dorkings, Brahmas, Spanish, or Game fowls to move about in any direction without discommoding each other, thus also affording every visitor the most easy opportunity of narrowly examining every bird shown without the waste of a single moment. This

was a subject of general comment at the Manchester Show; and we hope that so truly important a feature in the arrangements of an exhibition will thus force itself again on the consideration of the Managing Committee of the Birmingham Meeting, where the pens have, unfortunately, of late been so injudiciously circumscribed, that when the larger varieties of poultry are penned, it at once becomes alike impossible for arbitrators or the public to see them properly, besides inflicting an amount of permanent injury on birds that certainly deserve, and ought to receive, a far greater amount of accommodation.

But to return to the pens at Manchester. These pens were provided with quite a new appliance; each had an iron bar that ran through both top and bottom, provided at the upper end with a loop, through the whole of which, from end to end of each tier of pens, a strong piece of wire was tightly strained, making it impossible for any of the birds to be interfered with by strangers. The eggs laid were instantly removed; and, as a further proof of the determination to stand aloof of even suspicion, every egg was at once broken at one end before placing it in the basket provided for their reception—a plan which should be universally adopted; as, to our knowledge, surmises of no very pleasant character have suggested themselves in recent cases to the minds of the proprietors of the fowls laying, by themselves afterwards witnessing the eggs (when not broken on the spot when first taken from the pens), being afterwards carefully packed to go no one professedly knew where.

It is not open to a doubt that the only legitimate purpose to which the eggs laid during an exhibition ought to be applied by any Committee are strictly those of a culinary nature: consequently the plan that was pursued at Manchester prevents the possibility of objection, for, being publicly broken, collusions of all kinds are prevented.

One of the most striking peculiarities of the Belle Vue Show was how uniformly excellent were the birds exhibited, this arising, most probably, from the fact of 10s. each pen being the rate of admission. This, of course, kept indifferent pens from being entered at all, and it was remarkable that scarcely any pens entered were not sent, for, as observed by a visitor, "Ten Shillings is too much to throw away without sending them." It is gratifying also to state that the awards were all completed before the time of public admission. This was effected by dividing the classes, as will be seen by reference to the appended prize list, among the various arbitrators; some of those gentlemen having actually completed their arbitrations in half the time placed at their disposal. Nothing that could insure this speed and regularity remained unappointed.

The classes for Silver-Grey *Dorkings* headed the list, and unexpectedly we found this really useful and beautiful variety not nearly so well represented as we anticipated—in fact, they were one of the weakest classes in the Exhibition. The cocks, almost without an exception, were either partially white-tailed or more or less spotted with white on the throat and breast, both of which are fatal objections, as both the breast and tail should be purely black. In the class for Silver-Grey *Chickens*, there were exhibited a pair of pullets, a bright clay colour, causing some merriment, and others slightly spotted with white. These palpable mistakes (attended, too, with an expenditure of 10s. entrance money in each instance), proves that the peculiarities of these birds are not generally understood. In the classes for coloured *Dorkings* except Silver-Greys, as might be expected, the rivalry was indeed severe. Viscountess Holmesdale, however, maintained the highest position by taking three first prizes for this breed alone. We may confidently state not an indifferent pen could be found throughout the collection, though the entries were some of the heaviest in number in the Show. The White *Dorkings* were few but good.

The *Spanish* classes come next in order, and proved a really meritorious collection, being by far the best we ever yet saw; Messrs. Rodbard, Martin, Tebbay, Potter, Hyde, and Smith exhibiting birds of as close an approach to perfection as can ever be expected to be attainable. The quality of the faces and perfect condition of the majority of the male specimens was remarkable, and evidently proved that all the winning birds had been especially reserved for the competition at Manchester.

We next come to the *Cochin-China* classes, decidedly among the great guns of the Exhibition. The number of entries in each of these classes was the best proof they still have many admirers. It was quite a treat to see four such pens as those that took prizes in the adult Buff class. Mr. Tomlinson, of Birmingham stood first with as good a pen as were ever yet sent

out by even that gentleman. Their character and condition were excellent, their size was unusual, and the matching of the pen perfect. Mrs. H. Fookes, in taking second place, showed a pair of the most lovely hens we have seen for a long time past, and the same remark is alike applicable to Mr. Bates' pen; but in the male birds Mr. Tomlinson easily gave these rivals the go-by. The class for chickens was but little if at all inferior to that of the old birds. Greater competition as to regularity of quality in well-filled classes never occurred at any Show than in the Partridge-coloured *Cochins*. Many breeders of this popular variety stated that "it was well worth a long journey to see these birds alone." By referring to the prize list it will be seen old names held position against a host of new comers. The White *Cochins* were nicely shown and of very high quality.

The *Malays* were not so good as we have seen at many other recent shows.

The best of the *Polands* were the White-crested and the Silver-spangled. The Golden-spangled ones disappointed most visitors.

We are now arrived at the Golden-pencilled *Hamburghs*. We pity the man who indulges the vain hope of ever seeing better, perfection being the order of the day. The birds exhibited by the Rev. T. L. Fellowes and Mr. J. Munn were constantly admired, and had not the arrangements of space in the avenues between the pens been so liberal and commodious, an absolute block-up by visitors must have ensued at the front of these particular pens. Nothing of the kind, however, occurred, and every one had ample opportunity of seeing them. The Silver-pencilled *Hamburghs* were not nearly so meritorious; and it certainly struck the breeders of this variety that the first prize in the old birds was a mistake of the Judges altogether. The Golden-spangled and Silver-spangled *Hamburghs* were excellent classes throughout.

Never were the *Game* classes in better trim than at Manchester. Pen after pen was shown in faultless condition and true to feather; Mr. Fletcher's Black-breasted Reds, Mr. Robinson's Brown Reds, and Mr. Harry Adams's Duckwings and Red Piles being the most noteworthy.

The *Game Bantams* were exquisite specimens, comprising a very large entry and scarcely a pen unworthy of notice. The other Bantams were few in numbers, but very good.

The Rouen *Ducks* were the best of the Duck classes, the first prize of £6 falling to a name quite new to us. This is as it should be: it causes old breeders to look to their colours.

The *Pigeons* were a marvellously good display, Mr. Peter Eden's Pouters, Carriers, and Barbs being among the highest ranks of perfection throughout the whole Show. We must also briefly allude to a pair of wonderfully good Mottled Runts shown by Mr. Baile, of London. The Owls were also particularly good.

We cannot conclude without congratulating the projectors on this more-than-even-anticipated success of their second Exhibition. In such hands the result is certain: progress will be the order of the day. Strange as it may appear to those who have not visited Belle Vue Gardens, the great Music Hall would, with perfect comfort, easily accommodate twice the number of entries of even the Show just closed, and the manner in which the birds have this year, as well as last, been treated has been such that increased public confidence must, beyond question, ensue.

As the weather proved so spring-like there was no cause for heating the Hall this year; otherwise had stress of hard weather taken place the whole could have been at once heated, and the comforts of both visitors and poultry provided for. Enjoying so many unusual advantages for holding such meetings, combined with the same civility to high and low, rich and poor, we have no doubt that Manchester will take its place in the very foremost ranks of our poultry exhibitions.

DORKINGS (Silver-Grey).—First, J. Dixon, Bradford. Second, Mrs. Hill Woodlands, Heywood. **Cock.**—Prize, T. Statter, Stand Hill, Whitefield. **Hens.**—First, E. Musgrove, Aughton, near Ormskirk. Second, J. K. Fowler, Aylesbury. **CHICKENS.**—First, G. Cargay, Stone. Second, T. Statter. Third, W. R. Court, Middlewich. **Cockerel.**—First, T. Statter. Second, R. Carr, Towngate, near Preston. **Pullets.**—Prize, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks.

DORKINGS (Coloured, except Silver-Grey).—First, W. Copple, Eccleston, Prescott. Second, T. Burgess, Whitechurch, Salop. Third, Viscount Holmesdale, Staplehurst, Kent. Highly Commended, E. Tudman, Whitechurch, Salop. Commended, Viscount Holmesdale; Mary Hill Woodlands, Heywood. **Cock.**—First, Viscount Holmesdale. Second, Mrs. Rothery, Halsemere, Surrey. Third, E. Tudman. Highly Commended, E. Smith, Middleton. **Hens.**—First, H. W. B. Berwick, Helmsley, Yorkshire. Second, Mrs. A. Guy, Eaton, near Grantham. Third, J. Robinson, Garstang.

Highly Commended, E. H. Garrard, Broadway, Worcester. CHICKENS.—First, Viscount Holmesdale. Second, W. T. Everard, Barton Hill House, near Ashby-de-la-Zouch. Third, J. Holme, Knowsley, near Prescott. Fourth, C. H. Wakefield, Malvern Wells. *Cockerel*.—First, E. Tudman. Second, E. Shaw, Plus Wilmot, Oswestry. Third, Mrs. Hill. Highly Commended, Rev. J. G. A. Baker, Biggleswade, Beds. Commended, T. Rigby, Penny Wood, Winsford. *Pullets*.—First, Viscount Holmesdale. Second, T. E. Kell, Wetherby, Yorkshire. Commended, G. Potter, Fallowfield, Manchester.

DORRINGS (White).—Prize, Mrs. H. Fookes, Whitechurch, Blandford. *Cock*.—Prize withheld. CHICKENS.—Prize, W. Chamberlain, Desford, near Leicester.

SPANISH.—First, J. Martin, Bingley. Second and Third, R. Teebay, Fulwood, near Preston. Highly Commended, R. B. Postans, Brentwood. *Cock*.—First, J. R. Rodbard, Writington, near Bristol. Second, J. Potter, Droylsden. Third, T. P. Wood, Boythorpe House, near Chesterfield. Fourth, J. W. Smith, Northamptonshire. Highly Commended, R. Teebay. Commended, J. Suddal, Halifax. *Hens*.—First, S. A. Hyde, Ashton-under-Lyne. Second, J. Shorthose, Newcastle-upon-Tyne. Commended, H. Lane, Bristol. CHICKENS.—First, R. Teebay. Second, H. Lane. Third, E. Brown, Sheffield. Fourth, E. C. Monk, Fleetwood. Highly Commended, H. Yardley, Market Hall, Birmingham. *Cockerel*.—First, J. Potter. Second, H. Lane. Third, S. Robson, Brotherton, Barton Salmon. Commended, J. S. Lowndes, Aylesbury. *Pullets*.—First, J. W. Smith. Second, H. Lane. Third, Mrs. Craigie, Chigwell, Essex. Highly Commended, Mrs. Craigie.

COCHIN-CHINA (Cinnamon and Buff).—First, H. Tomlinson, Birmingham. Second, Mrs. H. Fookes, Whitechurch. Third, H. Bates, Birmingham. Fourth, E. Musgrove, Aughton, near Ormskirk. Highly Commended, J. E. Walthew, Aughton, near Ormskirk. *Cock*.—First, T. Boucher, Birmingham. Second, H. Bates, Birmingham. Highly Commended, E. Smith, Middleton. *Hens*.—First, Master J. T. Smith, Middleton. Second, H. Bates. Commended, W. Copple, Eccleston, Prescott. CHICKENS.—First, G. Fell, Warrington. Second, H. Tomlinson, Birmingham. Third, T. Stretch, Ormskirk. Commended, E. Musgrove; H. Bates. *Cockerel*.—First, J. Potter, Droylsden. Second, J. Elliott, Leigh. Third, R. White, Sheffield. *Pullets*.—First, Rev. G. Gilbert, Norwich. Second, H. Bates.

COCHIN-CHINA (Brown and Partridge-feathered).—First, E. Musgrove. Second, E. Tudman, Whitechurch, Salop. Third, J. Shorthose, Newcastle-upon-Tyne. Highly Commended, R. Chavasse, Birmingham. Commended, T. Stretch. *Cock*.—First, J. Shorthose. Second, E. Tudman. Highly Commended, J. Holme, Knowsley, Prescott. *Hens*.—First, Capt. Heaton, Manchester. Second, J. B. Walthew, Ormskirk. Highly Commended, E. Tudman. CHICKENS.—First, T. Stretch. Second, Capt. Heaton. Third, E. Tudman. *Cockerel*.—First, R. White. Second, E. Tudman. *Pullets*.—First, J. B. Walthew. Second, E. Smith, Middleton.

COCHIN-CHINA (White).—First, R. Chase, Birmingham. Second, G. C. Whitwell, Kendal. Third, F. W. Zudhorst, Dublin. *Cock*.—Prize, R. Chase. CHICKENS.—First, R. Chase. Second, G. Blyth, Birmingham. Third, W. Copple, Eccleston, Prescott. *Cockerel*.—Prize, D. Causer, Birmingham.

BRAMA POOTRA.—First and Second, R. Teebay, Fulwood. *Cock*.—Prize, R. Teebay. CHICKENS.—First, J. K. Fowler, Aylesbury. Second, Mrs. M. Seamons, Aylesbury. Third, J. Pares, Chertsey. Commended, R. Teebay. *Cockerel*.—Prize, R. Teebay.

MALAYS.—First, withheld. Second, N. Sykes, jun., Mile End, London. *Cock*.—Prize, G. H. Evans, Lancashire. CHICKENS.—First, J. Choyce, jun., Atherstone. Second, N. Sykes, jun. *Cockerel*.—First, withheld.

POLAND (Black, with White Crests).—First, H. Carter, Holmfirth. Second, J. Dixon, Bradford. *Cock and two Pullets*.—Prize, J. Dixon. *Cockerel*.—Prize, S. Farrington, Chat Moss, Manchester.

POLAND (Golden).—Prize, J. Dixon, Bradford. *Cock*.—Prize withheld. CHICKENS.—Prize, J. Dixon.

POLAND (Silver).—Prize, J. Dixon. *Cock*.—Prize, J. Dixon. CHICKENS.—Prize, W. Newsome, Bingley. *Cockerel*.—Prize withheld.

ANY OTHER DISTINCT VARIETY.—Commended, D. Howarth, Manchester.

HAMBURG (Golden-pencilled).—First, Rev. T. L. Fellowes, Norfolk. Second, J. Munn, Newchurch. Third, A. Nuttall, Newchurch. *Cock*.—Prize, J. Garts, Bradford. CHICKENS.—First and Second, J. Munn. Third, Rev. T. L. Fellowes. Fourth, Mrs. W. Kershaw, Heywood. *Cockerel*.—First, Mrs. W. Kershaw. Second, J. Robinson, Garstang. Third, W. Rothwell.

HAMBURG (Silver-pencilled).—First, D. Harding, Cheshire. Second, J. Martin, Worcester. Third, W. Cannan, Bradford. CHICKENS.—First, J. Martin. Second, T. W. Walsh, Worcester. Third, G. Addison, Bradford. Fourth, J. Dixon, Bradford. *Cockerel*.—Prize, S. Fielding, Middleton.

HAMBURG HENS (Pencilled).—Prize, J. Munn, Newchurch. *Pullets*.—Prize, J. Robinson, Garstang.

HAMBURG (Golden-spangled).—First, J. Davies, Birmingham. Second, P. Swindells, Stockport. Third, S. H. Hyde, Ashton-under-Lyne. Highly Commended, W. Cannan, Bradford; H. Carter, Holmfirth. *Cock*.—Prize withheld. CHICKENS.—First, S. H. Hyde. Second, N. Marlor, Denton. Third, G. Whittaker, Bolton. Fourth, J. Dixon, Bradford. Highly Commended, J. Roe, Manchester. *Cockerel*.—First, J. Mellor, Slaithwaite. Second, J. Buckley, Ashton-under-Lyne. Third, P. Swindells.

HAMBURG (Silver-spangled).—First, J. Dixon, Bradford. Second and Third, H. Dale, Middlewich. *Cock*.—Prize, J. Robinson, Garstang. CHICKENS.—First and Second, J. Fielding, Newchurch. Third, J. Robinson. Fourth, W. Cannan, Bradford. *Cockerel*.—First, J. Dixon. Second, P. Swindells, Stockport.

HAMBURG HENS (Spangled).—First, H. W. B. Berwick, Yorkshire. Second, J. Roe, Manchester. *Pullets*.—First, H. W. B. Berwick. Second, S. H. Hyde, Ashton-under-Lyne.

GAME (Black-breasted Reds).—First, J. Stubbs, Stafford. Second, C. Chaloner, Sheatley, Notts. Third, J. Fletcher, Manchester. Fourth, H. Adams, Yorkshire. Fifth, E. H. Sykes, Stockport. *Cock*.—First, C. Chaloner. Second, J. Stubbs. Third, J. Fletcher. Fourth, J. Wharin, jun., Rotherham. Highly Commended, J. S. Butler, Poulton-le-Fylde; H. Adams. CHICKENS.—First, J. Fletcher. Second, J. Martin, Worcester. Third, S. Matthew, Suffolk. Fourth, W. Bourne, Newton Heath. Fifth, G. Cargay, Stone. Highly Commended, J. Stubbs; A. B. Dyas, Madeley, Salop. *Cockerel*.—First, T. Whittingham, Naatwich. Second, N. Grimshaw, Burnley. Third, S. Matthew, Suffolk. Fourth, T. Bottomley, Halifax. Fifth, S. Harrop, Manchester.

GAME (Brown and other Reds, except Black-breasted).—First, T. Robinson, Ulverstone. Second, C. Chaloner, Sheatley, Notts. Third, J. Fletcher,

Manchester. Fourth, H. Adams, Yorkshire. Fifth, C. Cargay, Stone. Highly Commended, T. Statter, Whitefield; T. Robinson. Commended, R. Swift, Notts. *Cock*.—First, R. Swift. Second, T. Statter. Third, C. Chaloner. Fourth, N. Grimshaw, Burnley. Fifth, T. Moss, Poulton-le-Fylde. Highly Commended, T. Howarth, Manchester. CHICKENS.—First, S. Matthew, Suffolk. Second, J. Wood, Wigan. Third, J. Fletcher. Fourth, H. Adams. Fifth, R. Swift. Highly Commended, H. Parker, Shropshire; G. Cargay. Commended, R. Peacock, Gorton Hall. *Cockerel*.—First, J. Wood. Second, G. Clements, Birmingham. Third, N. Grimshaw. Fourth, A. B. Dyas, Madeley, Salop. Highly Commended, J. Fletcher.

GAME HENS (Black-breasted and other Reds).—First, N. Grimshaw, Burnley. Second, H. Adams, Yorkshire. Third, W. T. Everard, Ashby-de-la-Zouch. *Pullets*.—First, J. Stubbs, Stafford. Second, J. Wood, Wigan. Third, R. Parkinson, Poulton-le-Fylde. Highly Commended, W. Pares, Derby; J. Camm, Southwell, Notts.

GAME (Duckwings, and other Greys and Blues).—First, H. Adams, Yorkshire. Second, J. Fletcher, Manchester. Third, W. Kershaw, Heywood. CHICKENS.—First, J. Martin, Bingley. Second, J. Hodgson, Bradford. Third, J. Stubbs, Stafford.

GAME (except Black-breasted and other Reds).—First, E. Needham, Chesterfield. Second, J. Wilders, Grantham. Third, J. Hindson, Liverpool. Fourth, J. Grocott, Cheshire. Highly Commended, E. Viggor, Cheshire. CHICKENS.—First and Second, J. Fletcher, Manchester. Third, J. Wood, Wigan.

GAME (Black and Brassy-winged, except Grey).—First, J. Fletcher, Manchester. Second, T. Burgess, Whitechurch. CHICKENS.—Prize, J. Fletcher.

GAME (White and Piles).—First, H. Adams, Yorkshire. Second, A. Guy, Eaton. Third, J. Camm, Notts. Highly Commended, J. Fletcher, Manchester; S. Matthew, Suffolk. CHICKENS.—First, H. Adams. Second, J. Wilders, Grantham. Third, B. W. Bretherton. Fourth, A. Hartley, Rochdale. *Cockerel*.—Prize, J. Fletcher.

GAME HENS (except Black-breasted and other Reds).—First, H. Adams, Yorkshire. Second, J. Hindson, Liverpool. CHICKENS.—Prize, W. Pares, Derby.

GAME BANTAMS (Black-breasted and other Reds).—First, T. H. D. Bayly, Biggleswade, Beds. Second, J. Grocott, Cheshire. *Cockerel and two Pullets*.—First, J. W. Kelleway, Isle of Wight. Second, J. Camm, Notts. Third, T. H. D. Bayly. Fourth, E. Yardley, Sheffield. Highly Commended, E. Musgrove, Ormskirk.

GAME BANTAMS (Any other variety).—First, C. W. Brierley, Rochdale. Second, R. B. Postans, Brentwood. *Cockerel and two Pullets*.—First, J. Camm, Notts. Second, R. Hawkesley, Southwell. Third, M. Billing, jun., Southwell. Highly Commended, R. Hawkesley; W. Lawrenson, Poulton-le-Fylde.

GAME BANTAM COCKS.—First, J. Munn, Newchurch. Second, R. B. Postans, Brentwood. *Cockerel*.—First, W. Lawrenson, Poulton-le-Fylde. Second, R. Swift, Southwell. Third, J. W. Kelleway, Isle of Wight. Fourth, T. H. D. Bayly, Biggleswade, Beds. Highly Commended, R. Hawkesley, jun., Southwell.

BANTAMS (Gold-laced).—Prize, P. Norbury, Timperley. *Cockerel and two Pullets*.—Prize, J. Dixon, Bradford.

BANTAMS (Silver-laced).—Prize, T. H. D. Bayly, Biggleswade, Beds. *Cockerel and two Pullets*.—Prize, R. M. Stark, Hull.

BANTAMS (White, Clean-legged).—First and Second, E. Holdsworth, Leeds. Highly Commended, T. H. D. Bayly, Biggleswade, Beds. *Cockerel and two Pullets*.—First, J. Dixon, Bradford. Second, J. Rumsey, South Hackney.

BANTAMS (Black, Clean-legged).—First, W. Cannan, Bradford. Second, T. Rigby, Winsford. *Cockerel and two Pullets*.—First, Miss M. Harrop, Manchester. Second, T. Rigby.

BANTAMS (Any other variety).—Prize, F. Musten. *Cockerel and two Pullets*.—Prize, P. W. Storey, Northamptonshire.

BANTAMS (except Game).—Prize, P. Robinson.

DUCKS (White Aylesbury).—First, W. Dolby, Rotherfield, Sussex. Second Third and Fifth, Mrs. M. Seamons, Aylesbury. Fourth, E. Viggor, Cheshire. DUCKS (Rouen).—First, G. Winn, Liverpool. Second, E. Longton, Liverpool. Third, J. Munn, Newchurch. Fourth, T. Statter, Whitefield. Fifth, R. E. Ashton, Bury, Lancashire. (Highly meritorious class.)

DUCKS (Black East Indian).—First, J. R. Jessop, Hull. Second, R. M. Stark, Hull. Highly Commended, F. W. Earle, Prescott.

DUCKS (Any other variety).—First, T. H. D. Bayly, Biggleswade, Beds. Second, J. Dixon, Bradford. Third, M. Hill, Woodlands, Heywood.

ORNAMENTAL WATER FOWLS.—Prize, J. Dixon, Bradford.

GESE (White).—First, W. Kershaw, Heywood. Second, Mrs. M. Seamons, Aylesbury.

GESE (Grey and Mottled).—First, W. Kershaw, Heywood. Second, J. Taylor, Stretford.

TURKEYS.—First, Mrs. A. Guy, Grantham. Second, J. Eckersley, Chorley, Lancashire. *Cock and two Hens*.—First, J. Smith, Grantham. Second, J. Dixon, Bradford.

EXTRA STOCK.—First, J. Harrison, Blackpool. Second, W. Chamberlain, Leicester. Third, C. Bocquet, Route D'Ivry, Paris.

PIGEONS.

POWTERS.—First and Second, F. H. Evans. Third, P. Eden, Salford. (Highly meritorious class.)

CARRIER COCK (Black).—First, E. S. Corker, Croydon. Second, J. Wadsworth, Halifax. *Any other colour*.—First, T. Colley, Sheffield. Second, P. Eden, Salford. Very Highly Commended, P. Eden.

CARRIER HEN (Black).—First, E. S. Corker, Croydon. Second, P. Eden, Salford. Third, J. Wadsworth, Halifax. *Any other colour*.—Prize, P. Eden.

DRAGONS.—First, F. Esquilant, Oxford Street, London. Second and Fourth, T. Ridpath, Rusholme. Third, C. J. Samuels, Manchester. Highly Commended, J. Wadsworth, Halifax; T. D. Walker, Liverpool.

JACOBIANS.—First, F. Esquilant, London. Second, H. Morris, Forest Hill, Kent. Third, W. Carlton, Howden.

NUNS.—Prize, F. Elso, Bayswater.

RUNTS.—First, J. Baily, jun., Mount Street, London. Second, C. Bocquet, Route D'Ivry, Paris.

BARBS.—First, P. Eden, Salford. Second, A. L. Silvester, Birmingham. Third, T. D. Walker, Liverpool.

TURBITS.—First, F. Elso, Bayswater. Second, A. L. Silvester, Birmingham.

OWLS.—First, F. Elso, Bayswater. Second, H. Morris, Forest Hill, Kent. Third, H. Yardley, Birmingham. Fourth, T. Ridpath, Rusholme.

TRUMPETERS.—First, W. H. C. Oates, Newark. Second, J. Baily, jun., Mount Street, London. Third, C. J. Samuels, Manchester. Highly Commended, F. Key, Beverley.

FANTAILS.—First, J. W. Edge, Birmingham. Second, T. Ridpath, Rusholme. Third, F. Else, Baywater.

ALMOND TUMBLERS.—First and Third, P. Eden, Salford. Second, E. T. Corker, Croydon. Commended, H. Clegg, Oldham; J. Cheetham, Rochdale.

BALDS.—First, F. Esquilant, London. Second, J. W. Edge, Birmingham.

TUMBLERS (Any other variety).—Prize, J. Cheetham, Rochdale.

BEARDS.—First, W. H. C. Oates, Newark. Second, F. Else, Baywater.

Third, F. Esquilant, London. Commended, T. Ridpath, Rusholme; J. W. Edge, Birmingham.

ANY OTHER NEW OR DISTINCT VARIETY.—First, A. L. Silvester, Birmingham. Second, Lady E. Talbot, Knowsley, near Prescott. Third, A. F. Leite, Manchester.

JUDGES.—*Poultry*: Edward Hewitt, Esq., Eden Cottage, Sparkbrook, Birmingham, and G. J. Andrews, Esq., Dorchester—Classes 1 to 42; J. Douglas, Esq., Ranton Abbey, Staffordshire, and T. Chaloner, Esq., Whitwell, Chesterfield—Classes 81 to 119; W. Lloyd, Esq., Waverham, near Northwich, Cheshire, and Philip Castang, Esq., London—Classes 43 to 80, and 120 to 129. *Pigeons*: T. J. Cottle, Esq., Pulteney Villa, Cheltenham.

HECKMONDWIKE POULTRY SHOW.

THE first annual Exhibition of Single Cocks took place on Friday, the 26th ult., at the Royal Hotel, Heckmondwike, when there was a first-rate display of Game and other cocks.

GAME (Reds).—First, H. Beldon, Bradford. Second, H. Hatton, Cleckheaton. Third, H. C. Mason, Drighlington. (The competition was so severe in this class that the Judges were obliged to give a third prize.)

GAME (Duckwings).—First, W. H. Atkinson, Heckmondwike. Second, H. Beldon, Bradford.

GAME (White and Piles).—First, H. C. Mason. Second, H. Beldon.

GAME (Blacks and Brassy-winged).—First, G. Noble, Heckmondwike.

Second, T. Hartley, Gomersal.

GAME BANTAMS (Red).—First, I. Goodhull, Heckmondwike. Second, J. Wilson, Dewsbury Moor.

GAME BANTAMS (Duckwing).—First, T. Hirst, Batley Carr. Second, C. Lister, Mirfield.

BANTAMS (Black).—First, J. Parker, Heckmondwike. Second, H. Beldon.

BANTAMS (White).—First, J. Elam, Heckmondwike. Second, H. Beldon.

ANY OTHER VARIETY.—First, T. Greenwood, Dewsbury (Black Spanish). Second, H. Beldon (Golden Poland). Third, H. Rushforth, Mirfield (Golden-pencilled Hamburg).

Messrs. William Marriott, Dewsbury, and Henry Wood, Great Horton, officiated as Judges, whose decisions gave great satisfaction.—J. THOENTON, *Hon. Sec.*

THE SCOTTISH NATIONAL POULTRY SHOW.

ON Christmas-day the first Show under the auspices of this National Society was held in the Queen's Rooms, Glasgow, and certainly, in every respect, it did credit to all the parties connected with it. The arrangements were complete. The entries amounted to 406 pens, including about 1200 fowls; the aggregate amount of the prizes awarded was about £150; and the attendance, notwithstanding the inauspicious character of the weather, was very numerous, including our leading citizens, accompanied by ladies and gentlemen from Edinburgh and other parts of Scotland, and a few from the South.

This Society was originated at the end of last summer, with the view of improving the various breeds of poultry, and giving, if possible, an impetus to this branch of agriculture, as well as to enlist attention to the matter by others not engaged in agricultural pursuits. It had its origin in the fact that the Glasgow Agricultural Society had given up their winter show of poultry. This being regretted by many, a meeting was called, and a Committee appointed, with Mr. R. Cowan, Gordon Street, as Secretary; and a better Secretary could not have been found, for he has laboured most patiently, and spared no pains to insure the success of the splendid display now in the Queen's Rooms—for which poultry-fanciers and the public in general owe him a deep debt of gratitude.

Making a somewhat careful examination of the pens, the leading feature was most palpably the general excellence of the fowls; indeed there was not a bad bird in the whole Show, and very many that we have never seen equalled. In adult *Dorkings*, we state enough when we say that it comprised the winning birds from the recent leading English and Scotch shows; and, in the opinion of good judges, there never was a finer show of *Dorkings* exhibited. In the second class the fowls approached very close to each other, so that, as is often the case, the Judges did not satisfy all. The *Spanish* class never were better represented, a leading breeder from Lancashire carrying off the first

prize; and many of the best of our own county breeders also showed. The *Scotch Greys*—our national bird—were numerous and well represented. The show of *Cochin-Chinas* was perhaps the finest that has ever been seen together, and the Gold-pencilled and Gold-spangled *Hamburgs* were very numerous and very good. The *La Flèche* pen of Mr. D. Allen was probably the first of that breed ever shown in Scotland. The *Game Bantams* formed perhaps the most interesting class in the Exhibition, from the variety and beauty of their plumage.

Of *Rouens* there was undoubtedly one of the finest shows ever seen, and the Judges admitted that they never had so much difficulty in giving their awards as in this class. The *Turkeys* were in excellent condition; and such fowls as those which gained the first prize, and which were quickly bought by a great Scotch poultry-fancier, are seldom seen. The *Ganders* and *Geese* were also remarkably fine; the first-prize pen weighed 54 lbs., and the second 50 lbs.

We subjoin the names of the Judges, who were all from England, and their awards:—Mr. J. Douglas, Ranton Abbey, Staffordshire; Mr. E. Chaloner, Whitwell, near Chesterfield; and Mr. R. Swift, Nottinghamshire.

DORKING.—First, Earl of Wemyss and March, Harelaw, Longniddrie. Second, D. V. Allen, Inchmartine, Inchture. Third, H. W. B. Berwick, Helmsley, Yorkshire. Highly Commended, J. D. Wauchope, Dalkeith; D. V. Allen, *Chickens*.—First, D. V. Allen. Second, J. C. Wakefield, Thornliebank. Third, Earl of Wemyss and March. Highly Commended, J. D. Wauchope, Dalkeith. Commended, J. Anderson, Meikle; J. Gibson, Woolmet, Dalkeith.

SPANISH.—First, R. Teabay, Fulwood, Preston, Lancashire. Second, W. McIntyre, Coalhall, Stair, Ayrshire. Third, Miss B. Ridpath, Edinburgh. Highly Commended, J. K. Fowler, Aylesbury; W. Wilson, jun., Beith. Commended, W. Pettigrew, Driften, Lesmahagow. *Chickens*.—First and Second, W. McIntyre. Third, R. Teabay.

SCOTCH GREY.—First, W. Thomson, Glasgow. Second, W. Pettigrew, Driften, Lesmahagow. Third, R. Watson, Cathcart. Commended, S. Young, Kirkton Mill, Neilston. *Chickens*.—First, J. Gilmour, Broom, Stewarton. Second, W. Thomson, Glasgow. Third, J. Connell, Hillhead, near Johnston. Highly Commended, W. Thomson; S. Young.

COCHIN-CHINA.—First, Miss Biggar, Nethermilne, Moffat. Second, E. Smith, Middleton, near Manchester. Third, Miss E. A. Aglionby, Wighton, Cumberland. (The whole class highly commended). *Chickens*.—First, Miss E. A. Aglionby. Second, A. Patterson, Airdrie. Third, D. V. Allen. Commended, Countess de Flahault, Tullyhally Castle; E. Smith; D. V. Allen.

HAMBURG (Gold-pencilled).—First, W. H. Dyson, Horton Bank Top, Bradford. Second, J. C. Wakefield, Eastwood Park, Thornliebank. Third, W. Cannan, Adolphus Works, Bradford. Highly Commended, A. Glen, Erskine; C. W. Brierley, Rochdale. Commended, W. Gilmour, Stonehouse.

HAMBURG (Gold-spangled).—First, Mrs. W. Whitehead, Kingsland Road, Shoreditch, London. Second, N. Marlor, Denton, near Manchester. Third, W. Cannan, Bradford.

HAMBURG (Silver-pencilled).—First, Miss E. A. Aglionby. Second, J. C. Wakefield. Third, A. Yuill, Airdrie.

HAMBURG (Silver-spangled).—First, J. Stewart, Springhill, Barrhead. Second, J. C. Wakefield. Third, E. Collinge, Boarshaw, Clough, Middleton, near Manchester. Highly Commended, R. Teabay.

POLAND (any colour).—First and Second, Miss E. Beldon, Bradford. Third, Countess de Flahault, Tullyhally Castle, Kincardine-on-Forth. Highly Commended, A. Yuill; S. Neil, Airdrie.

ANY OTHER BREED.—First and Third, D. V. Allen (Brahma Pootra and La Flèche). Second, E. Hutton, Pudsey, Leeds (Black Hamburgs). Highly Commended, D. V. Allen (Crève Cœur). Commended, B. Barker, Wyseby Hill, Kirtlebridge (Chinese Silky fowl).

GAME (Black-breasted Red and other Reds).—First, J. Hodgson, Bradford. Second, J. Anderson, Meikle. Third, Miss E. Beldon, Bradford. Highly Commended, J. Wood, Haigh, near Wigan. Commended, J. Firth, Halifax; J. H. Macnab, South Arthurle, Barrhead. *Chickens*.—First, J. Anderson. Second, A. B. Dyar, Madeley, Salop. Third, J. Mollison, Ruthven, Meikle. Commended, J. Firth, Halifax; T. Moss, Poulton-le-Fylde, Lancashire.

GAME (Any other colour).—First, A. Guy, jun., Eaton, Grantham. Second, J. Hodgson, Bradford. *Chickens*.—First, J. Mollison, Meikle. Second, J. Wood, Moathouse, Haigh, near Wigan. Third, J. Crosland, jun., Wakefield, Yorkshire. Commended, J. Hodgson.

BANTAMS (Game).—First, W. R. Lane, Bristol Road, near Birmingham. Second, J. Anderson. Third, J. Crosland, jun. Highly Commended, Dr. Corbett, Barrhead. Commended, J. Crosland, jun.; Mrs. Gilmour, Shawburn, Hamilton.

BANTAMS.—First, J. Anderson. Second, E. Hutton. Third, G. J. Maclean, Edinburgh.

DUCKS (Aylesbury).—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, J. Smith, Breder Hills, Grantham, Lincolnshire. Third, H. Heyes, Springfield House, Barrhead. Highly Commended, A. Cameron, Bogside, by Springburn; H. Heyes; J. C. Wakefield. Commended, J. M'Cowan, Old Cumnock.

DUCKS (Rouen).—First, J. Gibson, Woolmet, Dalkeith. Second, Lord Kinnaird, Rossie Priory, Inchture. Third, D. V. Allen. Highly Commended, A. Cunningham, Craigends, Renfrewshire; W. M. Gilmour, Shawburn, Hamilton. Commended, J. Gibson, Woolmet, Dalkeith. (The whole class highly commended.)

DUCKS (Any other breed).—First, Countess de Flahault, Kincardine-on-Forth. Second, Mrs. W. Whitehead, Shoreditch, London. Third, E. Hutton. Highly Commended, D. V. Allen; A. Cunningham.

TURKEYS.—First, J. Smith. Second, D. V. Allen. Third, Mrs. A. Guy, Eaton, near Grantham. (The whole class highly commended.)

GESE.—First, J. K. Fowler, Prebendal Farm, Aylesbury. Second, H. Heyes, Springfield House, Barrhead. Third, D. V. Allen. (The whole class highly commended.)—(*Glasgow Herald*.)

YELLOW-LEGGED GAME BANTAMS.

You must know that I am a member of the "Yellow-legged Game Bantam fraternity," and my forefathers have gained many laurels in the days when yellow legs were considered the crack colour; but since the olive or willow understandings have become the rage, I and my brethren have been obliged to succumb, and at best get only a commendation.

Now although I cannot expect the high honours myself, I should be proud to see my progeny in the lists with some chance of success; and as I am about to mate with two of the opposite sex who have what are called blue legs, I shall take it a favour if you or any of your kind correspondents will inform me whether I and my blue-legged spouses are likely to produce the desired Willow.—UN COQ.

["Vous êtes poursuivi par un songe," no one has objected to your yellow stockings. When you won, they were not the cause; when you lost they were guiltless. If you will show yourself the worthier, willow legs will not save your antagonist. The alliance you propose will not, we fear, be successful; and since you are so ashamed of your continuations, that you would not wish them to be hereditary, we advise you to make a match with willow legs, and to centre your affections on those of your olive-branches that take after "mamma."]

SILVER-GREY DORKINGS.

SOME two years ago I had a little friendly controversy with you about the points of Silver-Grey Dorkings, and I am obliged once more to take up the pen on behalf of my favourites, which are threatened expulsion from Bingley Hall by no less a person than yourself, because, forsooth, there were only six entries in the adult class, and only two pens were considered worthy of a prize. Let us look, Mr. Editor, at a few facts. There are five classes for Silver-Greys, and five for Spanish; the entries for the former are 71, and for the latter 59, giving rather over 14 as the average in the former, and not quite 12 in the latter. Again, there are 94 classes of poultry, and 1368 entries, being an average of about 14½ for each class—so that the Silver-Grey Dorkings, the latest, or rather the newest class, already come up to the average entry, and I have little doubt but that they will go on increasing, for "the coloured Dorkings" (not Silver-Greys) cannot for a moment be compared to them for beauty, and you acknowledge we are fast coming up to them in size. Let us look at the two classes as we go along—first at the Silver-Greys—all the pens uniform in colour, the cock with black breast and tail and beautiful light hackle; the hens such lovely grey bodies, and black and white hackles. What a contrast to the coloured class!—scarcely two pens alike in colour; but I will not attempt to describe them, but refer you to the letter of "E. C." in your Number of December 9th, where he dilates upon mottled breasts, white tails, and light and dark highly-commended pullets, &c. Surely, Mr. Editor, I have written enough to prove that the Silver-Greys are worthy of a class in Bingley Hall, and at all first-rate shows.—A BREEDER OF SILVER-GREYS.

[We are anxious to give you all the adhesion we can, but we still think we are right. It is for the breeders of these beautiful birds to correct us if wrong. That cannot be done on paper. The increase in the entries of old birds next year will be the most convincing argument. We have strong doubts as to the possibility of breeding them with certainty of producing colour. We bred last year from a cock in which we could detect no fault; the hen this year moulted with a white breast halfway down. If in the adult state, the points of perfect beauty disappear, they become that from which they sprung, and which are despised by the "Silvers." They are "Greys." If our correspondent can prove they are a breed, we will at once concede they are far more beautiful than the Greys or coloured.]

DZIERZON'S BEE-HIVE IMPROVED.

In your Number for November 25th, 1862, you give a drawing and partial description of Dzierzon's bee-hive. Will you kindly give one of your readers, who had not the opportunity of seeing it at the International Exhibition, such a description of it as may enable an ordinary mechanic to make one? It is especially desirable to have very clear directions as to the making and fixing the frames. Not understanding German, I shall be

thankful to be told the meaning of the word "lager."—A BEE-KEEPER.

[The German word "lager" has almost as many different significations as the English word "box." When applied to a bee-hive, it means "lying down." For instance: the "lager-stock" is a long hive only one storey high, something like our English collateral-hives, but having the entrance at one end, and consisting of only one compartment; whilst it differs entirely from the "Standerstock," which stands upright, and accommodates two, or sometimes three tiers of combs.

The accompanying sketch represents one of the frames of the Danish hive described in page 688 of our last volume. The projection at A rests on a ledge in the central partition, whilst the other end is sustained by the small eye B, which slips on a little wire hook driven into the top of the hive. The frame is kept from vibrating to and fro, by the lower part dropping into one of the notches in a strip of wood running from front to back, as shown in the original engraving. If you bear in mind that the frames are all 9 inches wide, by 10 inches

deep inside, and that half an inch clear space should be left at their top, bottom, and sides, whilst they are so arranged as to be exactly 1½ inch from centre to centre, there will be little difficulty in determining the exact size of each compartment. The strips of wood of which the frames are made, are 1 inch broad and a quarter of an inch thick. We should commence by making a dovetailed "carcase," as it is technically called, of inch wood with partitions half an inch thick. The roof and pedestal should be separate and moveable.

The annexed sketch shows the mode of communication between the brood-room and the honey-room of each compartment. It will be perceived that a piece about 6 inches long by three-quarters of an inch deep is cut diagonally out of the edge of the partition next to the glass, and is kept in its place by means of a central screw. When in its original position the communication is of course closed, but is readily opened by turning it as indicated by the dotted outline.

In the Exhibition-hive the side of each compartment was closed by two panes of glass in frames of equal size, and meeting in the centre as shown in the engraving. If we were making a hive of this description we should prefer to have the two panes and their frames of unequal size, but corresponding to the dimensions of the brood-room and honey-room in each case.]

BEE-FEEDERS.

MR. GEORGE ELDRIDGE, brazier, Woodstock, makes my zinc bee-feeders, and would be most happy to do so for "H. A. H.," and they would cost 1s. each, with package. But as carriage also would ultimately have to be considered, would it not be better if "H. A. H." were to order them of the nearest tin-plate-worker? I advise a distinction and a difference to be made in feeding bees; the contrivance for early spring use which I adopt is made of zinc. It is 10 inches long in the trough, 1½ inch broad, two-eighths of an inch deep, having a rounded handle attached to it 1 foot long and about three-eighths of an inch in diameter. It is so simple that a child can apply it without danger to itself or the bees either; it has merely to be inserted at the entrance of the hive in the dusk of the evening, when the weather is not frosty, and drawn away again the first thing next morning. It holds between two and three tablespoonfuls of honey, and less than that will be quite sufficient at a time during this season of the year.

"H. A. H." wishes also to be informed how to make the autumn bee-feeder out of a fig-drum.

Procure an empty fig-drum—and I trust to be forgiven as I

say so at this festive time—having a depth of about $6\frac{1}{2}$ inches; take out the bottom and refix it an inch and a half higher up, filling up any cavities that may remain around it, or up the original closing at the side, with hot glue. Cotton wadding forced in firmly with a small chisel is also a very good substitute. Around the circumference at the bottom of the drum cut out three arched sections, rising an inch for each apex, leaving between each about 3 inches of the base as supports. Opposite each other and inside of the drum fix two upright pieces of deal $4\frac{1}{2}$ inches long, and four-eighths by three-eighths of an inch in substance, with very small screws from the outside. Then cut a circular piece from out of the lid of a papered hat-box, about one-eighth of an inch smaller in circumference than the inside of the drum, and cut two opposite niches or grooves out of it, so that it may relieve itself well of the uprights. Fasten with tin-tacks two thin strips of deal, an inch apart, parallel and across, to prevent the floater from warping. Tack on the under side, at right angles, four pieces of a cork cut three-eighths of an inch thick, and with a bare bodkin or knitting-needle heated red-hot pierce a quantity of holes over its whole surface, and form one central hole half an inch in diameter, and secure therein a strip of bended zinc to answer as a handle, and the bees will be enabled, through the agency of the central hole and the corks below, to clear away the food from the bottom. This self-acting float will effectually secure the bees from death by immersion from the downward progress of the food; and it will be a rare sight to watch them at an evening feast of this kind. It is gluttony perfectly typified, though really to be understood in the opposite sense as regards our little insect friends.

When I find occasion to feed in autumn I proceed as follows:—I cut a strip of thick cotton wadding about 2 feet 6 inches long by 2 inches broad, and encircle it upon the top towards the outside circumference of the hive, then quietly and quickly as possible ply-up the central piece of plaited straw, place upon the hive a narrow deal fillet half an inch wider than the hole, and immediately lay on the adapting-board; the fillet refuses the bees admittance under the board, for the central parts of straw hives are generally become sunken a little more or less—circumstances which I submit to, as I prefer my hives to be made of straw throughout. Now place the feeder upon the board over the orifice, and a large bell propagating-glass over the feeder; then, with a goose's wing—which should always be at hand in all bee-operations—waft off the bees that may be running about on the board, and cover the glass with a super-over-hive, and surmount with a milk-pan, which will bear the hive down upon the board, which presses the cotton wadding into the irregularities of the surface of the stock-hive, defying earwigs, woodlice, and all other insect depredators, which are sure to be on the alert on these occasions. In the course of about half an hour's time listen, and you will hear a sound as of a resounding sea.

My drum-feeder holds 8 lbs. of food. I supply it to the hive about six P.M. in August and at five P.M. if in October (I prefer August), and by nine next morning the bees have generally stored the food and mostly forsaken the feeder by about eleven A.M. I then, if it is in October, spread a piece of matting before the hive, remove the pans, super-hive, and glass and feeder; and when no more food is to be given, I place the feeder on the matting. I consider my stock-hives should weigh 30 lbs. each in the latter end of August. Then take off adapting-board, wadding, and fillet, secure the piece of plaited straw over the hole with three or four slender nails, waft off any stray bees with the wing, and replace the milk-pan on the stock-hive. With the wing I then move off what bees there are loitering about the feeder on to the piece of matting, because, in October especially, the ground is apt to be damp and cold, and the bees, either from being gorged or taken suddenly from the warm temperature of the hive, when they are brushed to the cold ground become numbed, and never rise more; whereas, alighting upon the dry matting, they recover and return to their hive. When more food is to be given, then I merely replace the bell-glass, super-hive, and pan, and return the feeder replenished in the evening.

Never feed them during the daytime. It incites the bees to roosting and to gadding about, and, what is worse, their portal is left in a great measure unguarded, which awakens in their neighbours their never-failing picking, and stealing, and fighting propensities. The bee food which I invariably make use of is composed in proportions of 1 lb. of loaf sugar, $\frac{1}{2}$ lb. of honey,

and $\frac{1}{2}$ pint of water to be dissolved in a stew-pan over a clear fire.

In conclusion, I will observe, that a quarter-of-a-peck measure is more likely to be on the premises than a fig-drum, which was the case with me last autumn, so I merely with some tacks as small as possible, fastened two parallel uprights inside the measure, driving the tacks from within in this instance. These formed a float after the manner above stated. I fashioned a wooden ferrule out of a lath an inch broad, cut away three three-inch segments, half an inch deep, out of its circumference, and placed the measure plished with food upon it, upon the adapting-board over the hive. Nothing could answer better, and it is a simpler matter of construction even than the drum, whilst the quarter-peck remains good for its other legitimate purposes all the year round.—UPWARDS AND ONWARDS.

SALT FOR PIGS.

I THINK Mr. Preston has not solved the question. An overdose of salt is a poison to all animals, and pigs are frequently so poisoned to my knowledge by bacon-brine. That they thrive at sea is because they get, in medical verbiage, *quantum salis*, and that much improves most animals—not, I think, excepting dogs, but those animals most that are subject to internal parasites.

I give my horse and my dogs salt as an alternative, nor do I forget myself or my friends; many of whom, especially of the poorer order, have expressed their satisfaction at a benefit from so easy a remedy as a spoonful of salt in a morning before breakfast, and continued daily for weeks if necessary.—QUARTZ.

[We think our correspondent has shot by-side the mark. The question raised was not whether an excess of salt is fatal to pigs, but whether in moderate quantity it is injurious or beneficial. Bacon-brine may be fatal, but fatal because it contains saltpetre, which is poisonous even in small quantities to other animals. We will add the following which came to us by the same post that brought the letter from "QUARTZ":—

"I HAVE seen salt given on a small scale to pigs, but with beneficial results, as they seemed to relish their food better with it, and it had no ill effect upon them. I fancy if those worthy folks who say it is injurious were to use it themselves at the same rate they have given it to their pigs, it would very likely disagree with them too, as the effects they ascribe to it are just what one might expect from an over-dose.—A. R.]"

OUR LETTER BOX.

BLACK BANTAMS AT DARLINGTON.—We have received an explanatory letter from Mr. Munn, but too late for insertion this week.

BLACK BANTAMS.—Will the "WILTSHIRE RECTOR," who wrote in this Journal of December 23 "A Plea for Bantams," inform "C. G." where she can obtain a cock and two hens of the pure Black Bantam breed, and at what price?

DEAD SILVER-SPANGLED HAMBURG PULLETS (*Gallus*).—The crops of both the birds you sent were quite empty, and there were no stones in the gizzard. Your feeding is good, and yet your birds look and dissect as if they died of atrophy. There was no appearance of the gizzard having had anything to do for days. Has their roosting-place any kind of flooring? Constant chill might have to do with it. We doubt not bread steeped in strong ale would save them, and, in the event of another case, advise you to try it freely.

LAYING AGE OF FOWLS (*A. B. M.*).—Pullets only lay in the winter; Cochins and Brahmas, hatched in May, will lay in the winter; Dorkings and Spanish, hatched in February, will also do so. It may be taken as a rule that Cochins and Brahmas lay when from twenty to twenty-four weeks old, and others at thirty to thirty-six weeks old.

BANTAMS IN A GARDEN (*Museum*).—We have often had occasion to notice that Bantams, and especially Sebright Bantams, do little harm in a garden.

CORAL (*Idem*).—There are naturally three kinds—white, red, and black. We never heard of the colours of the two last-named being whitened, for the colouring pervades the whole substance.

BUCKWHEAT FOR POULTRY (*A Subscriber*).—Buckwheat is good for change. Pheasants are not very fond of it, Partridges are; but neither care much for it in confinement. If a piece of it be grown, Partridges will feed on the stubble till all be ploughed-up.

PIGEONS (*Idem*).—Tiles make very good Pigeon-nests, as they do not harbour vermin like straw and wood. The shapes most adapted are those that are ridged and curved towards the edges. We have known flower-pot saucers used. We do not know where you can meet with Blue Rocks for your dove-cote.

DOE RABBITS EATING THEIR YOUNG ONES (*F. C.*).—Generally speaking only very young does eat their young ones. If they are kept quite away from the buck, are kept quiet, have a private place in which to kindle, and are plentifully supplied with every sort of green meat, especially parsley, they seldom eat their young.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 42.2° and 30.6° respectively. The greatest heat, 60°, occurred on the 19th, in 1823; and the lowest cold, 4½° below zero on the 19th, in 1833. During the period 147 days were fine, and on 105 rain fell.

THE PERSIAN RANUNCULUS:

A PLEA ON ITS BEHALF:

HAVE often wondered why this very beautiful flower is not more largely cultivated than it is. My own earliest associations as a lover of flowers are connected with it. I could not have been more than twelve years old when a schoolfellow took me to see his uncle's garden in the neighbourhood of Dublin. It

was a small plot, just such as many of those suburban residences have attached to them; and would, with its straight narrow beds, have given a landscape-gardener a fit of the blues. But the old gentleman's *spécialité* was the Persian Ranunculus. He was no florist; but being, I believe, somehow connected in business matters with Holland, had managed to bring together a very nice collection. Whether it was that my eyes were more easily satisfied then than they are now, or that the garden was well adapted for them, I know not; but although some thirty years and more have rolled over my head since then, and many a scene of far greater importance has passed from my memory, I see those beds of Ranunculus as clearly now as if they were veritably in bloom before my eyes. All shades of colour I recollect were there—ashy grey and purplish-black, brilliant yellows and glowing crimson, all kinds of spotted and edged varieties, and, I can verily say, such a bed I have never seen since; and if I have ever given the readers of THE JOURNAL OF HORTICULTURE any information that has been of use or stirred-up their flower-loving spirit, that bed of Ranunculus was the exciting cause of all my after-taste. It will hardly be wondered at that it should be a favourite flower, and that I should feel surprised at its not being more widely cultivated. Years after this a well-executed plate in the "Florists' Journal" stirred-up the old love which, perhaps, other plants had taken the place of, and I then set about growing them. My garden at that time was on a cliff overhanging the sea, exposed to every wind that blew; and yet, by dint of contrivance and perseverance I had a very nice bloom. Since then under varying circumstances I have cultivated them. Five or six years ago I had a beauteous bed of them in my garden here; but since that time my success has not been such as I had then. As next month is the best period for planting them I have thought that, perhaps, a few observations on them now might not be out of place.

I believe that one great reason for their being, comparatively speaking, so little grown, is that they are somewhat capricious in their blooming. But this applies mainly to the old Dutch varieties, many of which, such

as those that I saw in my boyish days, are perhaps now extinct; but during the last thirty years several very successful florists have been engaged in raising seedlings in this country, the two most celebrated being Mr. George Lightbody, of Falkirk, and Mr. Carey Tyso, of Wallingford, Berks. These seedlings are remarkable for their vigour of growth, great size, and above all, comparative certainty of bloom; and when we recollect that a flower whose home is the Levant has been acclimatised and made to seed in the cold uncongenial quarters of North Britain, we might naturally expect that it had acquired some hardness of constitution. So in truth it has; and at the same time one cannot help admiring the zeal and perseverance of our northern florists, who, nothing daunted by frost and snow, have in so many florists' flowers taken the lead of us in the south. To any one beginning their cultivation, I do not think I could give better advice than, Put yourselves into Mr. Lightbody's or Mr. Tyso's hands; tell them what you want, and you may rely on being well served. I know more of Mr. Lightbody's flowers than I do of Mr. Tyso's, and can unquestionably recommend them; and at the end of this short paper have given the names of a few I know to be good.

SOIL AND SITUATION.

A good deal has been said on this subject; and the great expense which is recommended by many growers has oftentimes, I am persuaded, frightened florists from attempting them. It is, I dare say, true that they can be best grown by taking out the soil of the bed in the autumn, and placing a good layer of well-decomposed cowdung about 6 inches below the surface: but this is not necessary. Any good rich garden soil, but without fresh manure, is suitable for them. When the natural soil is not good the beds must be made for them and filled-up with a mixture of loam, manure, and leaf mould, all well rotted together. As the Ranunculus delights in moisture an arid soil or a sunny situation does not suit them so well; but neither must the bed be placed under the drip of trees. In my own garden this is one of the great difficulties I have to contend with in the successful cultivation of the flower. We receive so much sun that it counterbalances the natural good condition of the soil.

MANAGEMENT.

The beds should be prepared in autumn, so that they need not be much disturbed in the spring when planting takes place. Should the weather be frosty it is a good plan to throw the surface up in small ridges to sweeten (as this winter we have not had a night's frost here, that has been impossible); and when the time for planting arrives the bed should simply be raked down smooth. It is a great mistake to raise the beds; they should be not more than an inch above the level of the walks. The 12th of February is the day which I have always fixed for planting; and in the successful execution of this depends half the future results. The bed being made quite flat, drills should be drawn about 5 inches from one another. In the bottom of this drill some white

Reigate sand should be sown; and the tubers then planted about 5 inches apart, and not more or less than $1\frac{1}{2}$ inch below the surface. The drills should then be covered in and the bed raked smooth. If the season should be a dry one they will require watering; but it is always best to do this between the rows, and not all over the bed. When the flower-buds begin to show colour it is time to have an awning of some sort ready to stretch over them, in order to prevent the effects of the scorching sun and heavy rains. Although the plant is so dwarf in habit it is not well to have the cover too low down, as this is apt to draw the plants; $2\frac{1}{2}$ feet at the sides, and about 4 feet in the centre is the correct height. After the bloom is over the covering should be taken off on all fine days, as it is very important to get the tubers up in a good state of preservation. If taken up too soon their vigour is spoilt; if left too long they are apt to sprout again, which is more injurious still. If the weather be very moist it is better to loosen the tubers by putting the trowel into the soil near them; but if dry this will not be necessary. When dried, put them into paper bags and keep them in a dry place.

CHOICE OF SORTS.

OLD DUTCH VARIETIES.

Angoulême	Feu Eclatante	Cillet Parfait
Apollo	Grande Monarque	Passe Niobe
Beauté Behemoth	Hercules	Reine de Portugal
Bishop van Lima	Jaune en Pompadore	Roi des Renoncules
Bouquet Sanspareil	Manteau Noir	Téméraire
Carlos	Mélange des Beautés	Tippoo Saib
Condorcet	Naxara	Voctonmox
Cossack	Ceil Noir	Voltaire
Fête Nocturne		

LIGHTBODY'S SEEDLINGS.

Cathcart	Hamlet	Saladin
Claimant	Jubal	Tubal
Creon	Melanethon	Virtuosa
Delictus	Miriam	Waldensia
Dr. Horner	Orsippus	Xerxes
Edgar	Paxos	Zwingle

I have only given the names of a few. Those in list No. 1 are mainly selfs; those in 2 and 3 spotted and edged. In all three classes there are a great many more equally as good, I dare say; but I have named those I know best.—D., *Deal*.

THE FRENCH FOUNTAINS—LIBRARY AT THE HORTICULTURAL SOCIETY.

NEW AND OLD CROCUSES.

In the monthly summary which closed the last year and in the last volume of the "Proceedings" of the Royal Horticultural Society, it is stated that the French Fountains (the worse luck) are now definitively abandoned, the amount subscribed having proved insufficient for the purpose, and the instructions of the subscribers with regard to the disposal of their subscriptions are now being taken. So far as is yet known, it would appear that the subscribers will unanimously direct them to be applied in the purchase of works of art for the decoration of the garden. Notwithstanding that the fountains are now out of question, "the subscription list will still be kept open, as it is understood that a number of the Fellows who would have subscribed for bronzes or general decorations have refrained from subscribing so long as the purchase of the fountains was in doubt."

There is much more than at first appears in that paragraph. The subscribers will most certainly not direct their money to be laid out in bronzes unanimously, and I for one do hereby protest against any more bronzes or brass, except the brass bands, for the new garden, until we have as good a library as the want of brass deprived us of on the fall and folly in Regent Street. But let bygones be bygones, and let us all join in the one pursuit which of all others is the most likely to contribute to the progress of the cultivators of the science and practice of gardening—the endeavour to place as good a skeleton of a garden and scientific

library at South Kensington as there is there now of what a town garden should be, and which embraces the period when the sister arts went hand in hand together with the science and art of gardening. I can very well understand the feeling in the Council of the Society on the subject of a library—they all feel our want of it as much as any of us; and they must also know the force of the feeling which the selling of the old library raised against the body. But let us all agree to forget what is not agreeable, and let us set on foot the really agreeable idea that ours will be the best library of the kind in the kingdom at some future time, if we set about it now with the French fountains' subscription sure in hand.

The best book I had for the last three months was the book on Crocuses; but the Crocuses themselves were still better. From the last day of September to the first day of January I have not been without a bloom of Crocus, or a pot of Crocuses in bloom, outside of the window-sill facing the south, and all with four kinds of wild Crocuses; and the last of them promises to run on to near the end of January. Well, then, what could be nicer than that for four of the dullest months? for, if October should be fine and fresh, still it is possible to keep back the October-flowering Crocuses to the beginning of November by keeping the pots dry a month longer, or by not potting the bulbs so soon by a month. Speciosus was the first to bloom with me, and it was noticed at the time as so much like Leucocoryne xxioides in the light blue streaky colour. A botanical clergyman from the country wrote to me to say his speciosus was very different from the one I mentioned; and so it was, for his sort is Parkinson's pyrenaëus, which is the same as Sir E. Smith's nudiflorus, and is first called speciosus in the Supplement to "English Botany," vol. ii., fig. 2752.

This pyrenaëus of Parkinson and nudiflorus and speciosus of Smith is the same as the Crocus which is so abundant in the meadows at Nottingham. My speciosus is the true one, and was so named in the "Botanical Magazine," 3861, by Bieberstein, after whom the new *Cerastium Biebersteini* is called. He was a Russian botanist.

My present new-year bloomer looked so much like the true versicolor as to put me in the dumps about it, when the flower-buds made their first appearance about the middle of December. It is the Crocus Imperatorius of Herbert in the "Botanical Magazine," 3871, and the C. Imperati of Tenore, "Botanical Register," 1993. It is a native of Monte Pollino in Calabria, and farther south to the very spot where Garibaldi received the ball into his ankle. There are six blooms of it now open before me as I write this, and I see nine more coming in different stages, so that I shall be sure to have one bloom of it at least to the very last day of January, if not well on in February, as some more flower-buds may yet appear from among the foliage, which in this kind becomes 2 or 3 inches long before the flower-buds come up. In the bud this beautiful Crocus is a light yellow, or straw colour, streaked with purple-feathered stripes on the sepals. The inside of the sepals and both sides of the petals are of a rich violet colour (saturate violaceo); the bottom of the flower is smooth, and of an orange colour, like the eye in the breed of versicolor, and the size as large as that of Prince Albert. Altogether it is a very desirable Crocus coming naturally in the dead of winter, besides reminding one of a host of similar kinds, which might be within our reach if we once adopted the notion of cultivating a selection of them.

I am indebted to the kindness of the king of cross-breeders for them all, and his kinds came quite true to name. One of them, for which he had no name, and which he received from Dr. Herbert's brother, is the next on my list, and the third which bloomed with me. It is *odorus*, a lovely light blue flower all over, with a yellow bottom, and it bloomed for six weeks from the end of October, and is a very sweet-scented flower. It is the Crocus longiflorus of Rafinesque, an Italian botanist; but the name *odorus* was previously applied to it by another Italian, Bivona Bernardi, and there is a figure of it in the "Botanical Register" for 1844 (3, fig. 4), under the name longiflorus, together with that of another variety of it (fig. 5), which is a native of Malta.

The fourth kind of my stock is byzantinus, the oldest of them all, and one of Parkinson's Crocuses; it is also the most curious of all the Crocuses, and had several names—as banaticus, by M. Gay, of Paris; speciosus, of Reichenbach; and iridiflorus, of Dr. Heuffel; but Parkinson's name, byzantinus, having had the priority, is the right one. Before the flower opens one might be excused for taking it to be speciosus, the colours being much

the same. When it was fully open Dr. Heuffel was very near the mark in naming it *iridiflorus*; and M. Gay, in the "Bulletin de Férussac," having had it from the Banat of Hungary, and probably through Dr. Heuffel or Visiani, without a name, was not so far out either in naming it *banaticus*; but Parkinson had it through Constantinople, so it may have a long hilly range from the Banat eastwards.

Well, the oldest Crocus is still the most striking and the most singular flower of them all, and mine possessed a most singular feature which has not been mentioned by any author as far as I know. All my flowers, nine or ten, had four large spreading sepals, the first true irid flower I had ever seen with so many, and some had four petals, and some only the usual number—three. These petals are of a deeper blue than the sepals, and only about one-half their size; they stand apart in the centre, erect and not spreading, and at a short distance look very much like some Iris. Two good gardeners mistook my flowers for Iris. This and the Cloth of Silver of Parkinson had both been long lost until they were introduced again by Dr. Herbert, and many such, as it would appear, only to be lost again after his own loss to scientific gardening.

The twelve kinds I had from the far north are all growing, but none of them are autumnal or winter bloomers; and they may, probably, turn out to be merely garden seedlings, for I have no names yet for them, and I am afraid the names have been lost. But the old story again. I want more kinds of Crocuses, and I want no seedling Crocus but Mary Queen of Scots, which Mr. W. Paul exhibited the spring before last before the Floral Committee, and which I booked as so much larger than Sir Walter Scott. Any kinds of Crocus to bloom from September to February I want, except *speciosus*, *odorus*, *byzantinus*, and *Imperatoni*, and any kind I may obtain shall not be lost again for the next generation after me; but I would give a fair price for any authentic kind of the race of autumn bloomers.

To conclude this part of the subject I would remark, that the three weeks next ensuing is the best time of the whole year to pot Crocuses from the open border, so as to have them without much forcing a month or six weeks earlier than they will be from the open ground. If the patches or rows of Crocuses have been down twelve months, or a number of years, the best part of their roots is made before the middle of January, and the leaves are nearly on the surface by this time, in such a mild season as this, and it is under these conditions that all the difficulties of learning to force Crocuses vanish in practice. No one, therefore, need wait one day longer at trying his or her maiden effort at "early forcing," a subject which is music to the ears of an old gardener. So much is it so in my own instance, that the fire for keeping the seedlings on the move is constantly referred to as "the early forcing," while the fire to keep off the frost is of little or no account. But when I was in the very full of it, and had all sorts of bulbs and of Crocuses in forcing, I never missed lifting a certain number of patches about this time in addition; and with the same treatment as with forcing Asparagus I could always reckon on as early a bloom and a better one than that from potting dried bulbs after the middle or end of October. A mild, moist bottom heat was maintained, and the lights were slid down all day and tilted at night; but on the window-sill this style of early forcing is almost as good as any.

D. BEATON.

MELON CULTURE.

"F. B." has a greenhouse and a two-light frame, the command of plenty of stable manure, a good stiff loam in his kitchen garden, leaf mould, and access to road-scrappings, and he asks if with these, being quite a novice, whether he can grow Melons; and, if he can, how and where he should raise the plants.

Our reply may be useful to many similarly placed.

FIRST, FOR MODERATELY EARLY MELONS.—Begin now, and having obtained two good cartloads of stable manure, throw it together into a heap, mixing the short and the long regularly together, and watering if the straw part is very dry, and beating it down if there is much straw matter in it. Make the heap in a square shape in preference to a cone. When finished, throw a barrowload or two of long litter over it, to cause it to heat sooner and more regularly. In ten days or so you will see the heat steaming nicely. Remove the straw covering and lay it carefully aside, and turn the whole heap over carefully, placing the top at the bottom, and the outsides in the middle, shaking

it all regularly, and watering only with the rose of a pot where the manure seems dried and parched, and cover all over again with the long litter. In about the same time, less or more according to the weather, turn the heap again and cover as before, and most likely, in a week or so, the manure will be sweet and fit for your bed. Whilst these preparations are being made, take half a dozen barrowloads of your garden loam, a spit below the surface would be best, and put it in any place where it can be well aired and dried. Place also along with it a barrowload of road-scrappings, if free from weeds and very fresh leaves; and one barrowload of well-rotted sweet leaf mould. These will be quite sufficient for forming a ridge or two mounds in the centre of your bed. Whilst this is going on, the dung from the stables will have accumulated to a load or two—say two loads. Then fix upon a site for your two-light frame, and choose one where moisture will not accumulate, and mark out a piece of ground, at least 18 inches longer and 18 inches wider than the size of your frame. Shake on this the long unsweetened dung from the stables, keeping the sides and ends plumb or perpendicular, and then build upon that the fine sweetened dung you have been preparing. If your frame is rather shallow, you may make the sides in which the frame stands higher than the interior of the bed by 6 to 12 inches, and that will give you more room for soil, for the top of the soil should not be nearer the glass than from 15 to 18 inches. The soil should not be less in depth than from 15 to 18 inches. Put on the frame as soon as the bed has been made. If the bed has been equally beaten it will sink equally; but it is as well to wait a few days to see, and let the heat rise nicely and regularly. Then you may put in your aired soil, either as a ridge along the middle of the bed, or as a mound of two or three barrowloads in the centre of each light. As soon as this soil is warm, and from the clear condensed drops of water on the sash-bara and the sweet smell of the bed you can reckon that all is safe, you turn out your plants, either along the bed or two or three in the centre of each light. These plants we are supposing that you beg or borrow from some neighbouring gardener; if not, then sow as soon as the bed is up, pot-off, and plant-out as above; but thus you will lose much time. By the above mode, and using the stable manure for linings when the heat declines, you may have two crops of Melons from that frame before the nights become very cold in the autumn.

As soon as the roots fill the ridge or hills, the frame may be partly or wholly filled with mould, using well-aired soil round the hills, and the rather stiff soil of your garden trodden firm for the rest, and putting no manure with it unless it is very poor indeed. In the directions in late Numbers to which you allude, we do not agree either in the mode of stopping detailed, or in the rich soil stated to have been used. But the reasons for this have been repeatedly given, and you must exercise your own judgment.

You seem anxious to do everything for your plants yourself, and therefore we may state that you may raise your own plants in the greenhouse, and sow now, if you would make a small wooden hot-water box for yourself—say 2 feet square and 18 inches deep, or, better still, 15 inches in front and 20 inches at back. Fasten a tin, or plate-iron bottom across the box, 6 inches above the lower bottom, and on that plate place some rough sand, &c., for the pots to stand upon. The six-inch space below to be filled with a box, or drawer of zinc, tin, or plate-iron, which you can empty or fill at pleasure. From 3 to 4 inches of hot water—say twice in the twenty-four hours, would, with a covering of the glass lid at night, give plenty of heat for the Melons, and interfere nothing with the plants in the greenhouse, as a little more air could easily be given just opposite the box. The temperature of the box should range from 65° to 70°, with a rise of from 10°, 15°, or 20° in sunshine.

The bottom temperature of the dung-bed should average 80°, the atmospheric temperature of the bed at night may range from 60° to 65°; if as much as 70° leave a little air on. In favourable weather give air early in the morning, and then, if the sun raises the atmospheric heat to 80° or 85°, it will be all the better. Shading should not be resorted to unless in sudden changes. Much has lately been said as to watering.

A SECOND MODE FOR SECURING ONE GOOD CROP WITH LITTLE TROUBLE.—Secure plants by the second or third week in May, either by begging, buying, or raising them in the greenhouse as above described, sowing the seeds in the box in the first week of April. Choose an open place for the box, excavate the earth some 9 inches deep, placing the earth round,

so that the hollowed space will be about 18 inches deep. Place a few barrowloads of litter on the bottom, and then two cartloads of dung, thrown together about the 1st of April, but not so much sweetened as in the first case. Get that into the hole by the 1st of May, put your frame on with the earth close to the outsides, allow the heat to rise, level the surface nicely, cover with 15 inches of your stiff loam, let the sun have full access during the day, and cover up at night, and as soon as the soil from heat and sun is about 80° turn out your plants, tread the soil firm, and attend to air-giving, &c., as necessary; in fact, the training and air-giving will be pretty nearly all the trouble. The dung may be used less sweet, because covering the bed all over with soil, and tramping it firm, especially near the sides, will prevent all steam from rising. To prevent cracking, keep the surface loose for half an inch or so in depth.

A THIRD AND EASIER MODE.—Set your frame full south, raise it up behind, so as to give the glass roof an angle of 70° instead of 80°, which is the usual slope for a frame. The raising the ground for the frame to stand on will do all that; then remove some 6 inches or more of the natural soil, and supply with fresh incorporated with the old. About the middle of May keep the frame shut, and cover-up with mat or tarpaulin, in cold nights. The soil inside will soon become warm from the sun alone; turn the soil frequently, so that it may be heated all through, and by the 8th or 10th of June turn out the Melon plants that had been raised and hardened-off by degrees in the greenhouse. By such means, in the climate of Reading, where you reside, you may obtain fine Melons through the autumn.

THE FOURTH PLAN is what you should try if you wish to astonish your friends by giving them plenty of Melons as proofs of your good will. Your greenhouse is 30 by 18 feet; you do not say whether you have Vines in it or not, we presume not. You do not say where your heating medium is; we shall, for argument's sake, presume it is near the front. Well, in this case we would sow the seeds in the first or second week in April, even if you should want a second hot-water box for the seedlings, which, in this case, should be potted singly. By the 1st of June all the hardy greenhouse plants may be moved out of doors to a sheltered place. Such plants as Azaleas, Epacris, and even Camellias may be left at the back, a little shaded until they have formed their wood, and then be hardened-off by degrees. If floral decoration were deemed necessary, then grow such annuals as Cockscombs (common and feathered), Portulacas, &c., and such tuberous-rooted plants as Gloxinias and Achimenes, which will keep in a cool dry state in winter. Then we would have twelve large pots, set near or over the heating medium in front of the house, each pot about 15 inches in diameter at least, well drained, and filled to within an inch of the top with your good loamy soil, with nothing in it but a little sweet leaf mould. When the soil is warmed, turn out a stiff stout single plant in the centre of the large pot, water and shade a little for a few days until it is growing freely, and fasten the shoot to a string or rod, keeping it always, at the least, 15 inches from the glass. We prefer, for this work, that each plant should have only one shoot or stem, and that this should be a secondary and not the primary shoot of the plant. This was all recently explained, but we will recapitulate thus far. The primary shoot is the leading upright shoot of the seedling which the Melon sends up as naturally as the Oak. But we do not let this grow; on the contrary, as soon as it can be seen after two or three rough leaves are visible, the point is nipped-out with a penknife. This, of course, seems to arrest the growth of the plant for a little; but we have an object in view. Ere long two or three incipient shoots will appear instead of one. All are nipped-out with the point of a penknife when very small, except one, and this one we train and grow on from the pot, until, from the space at our command, the shoot is from 3 to 6 feet in length before stopping it at all. From every leaf of that shoot, or nearly so, at the point where the leaf joins the stem, would come first a little bud and then a shoot, what we think was previously called a tertiary shoot; and if we nipped-out the point of our main shoot, to throw strength into these side tertiary ones, almost every one of them would show fruit. We do not stop the main secondary stem so soon, and we pick-out every one of these incipient buds or shoots for more than half the length of what we intend the stem to be, because we do not wish our space to be filled with small shoots and foliage, and because we wish our plant to be strong and vigorous before any fruit shows. For this purpose, when we

do stop the point of our stem, we leave from six and onwards of these young shoots in the axils of the leaves unpicked-out, and these then come strong, show fruit boldly, and then themselves are stopped one joint beyond the fruit. So much for the front of the house. But it would be just as easy to cover the whole house with Melons, by having another range of pots on the stage at the back, which would give 9 feet of roof for each row, or a row might be placed likewise in the middle of the house, which, in addition to the front glass if there is any, and the length of the upright glass, will give fully 6 feet of roof for each set of Melon plants.

Be it clearly understood that, in disbudbing as above recommended, care should be taken that the older leaves on the stem should not be injured. All that is necessary to turn such a greenhouse into a first-rate melonry, is the removing all plants that extra heat would injure, and then using as much fire heat as would secure an average temperature of from 65° to 70°. If a little air is left on at night, and more given early in the morning, the plants will stand a rise of 10° to 15° from sun heat without injury; 60° would do at night if the roots had bottom heat, but without that, and as the pots will cool by radiation and evaporation, we would, in such cases, approve of from 65° to 70°. We know that fruit thus obtained will, in general, be much superior to those raised on dung-beds. We forgot to mention that, in trying Melons without any hot dung below the soil, the frame should be shut up early in the afternoon to enclose sun heat, and great care should be taken not to overwater, and at any rate to prevent the surface being deluged or sloppy. A few open drain tiles set upright, furnished with plugs, will enable you to keep the soil beneath moist enough, whilst the surface is dry. A flooring of slates over the soil would also absorb and then radiate the heat. These remarks apply to your specific circumstances, and we shall be glad both to give more details if necessary, and to hear of your success. R. FISH.

APRICOTS IN ORCHARD-HOUSES.

It is very satisfactory to be able to put "CONSTANT SUBSCRIBER" in the way of succeeding with Apricots under glass.

My trees have generally been too much crowded with fruit for some years past, and particularly in 1860 and 1861; but in 1862, in spite of what I thought to be good management, there was a failure, and on my large trees I had but half a crop, or barely that. Now I knew, when the trees were in blossom in April, that the dull, still, cloudy, moist weather was most unfavourable to the pollen being, as it should be, dry and dusty, and so I gave a portion of air to the house, even when the nights were frosty, so as to prevent stagnation. In spite, however, of all I did, the blossoms dropped by thousands, leaving but a scanty crop of fruit. I did not, as usual with us frail mortals, "do as I ought to have done;" I ought, on observing such unfavourable weather, to have had a pan of charcoal lighted at 9 A.M., have kept all the doors and ventilators open, so as to have brought on active currents of dry air, which, as is well known, a bright fire always does. The pan should have been replenished with fresh charcoal at 7 P.M., and this kept burning all night, with all the ventilators open. Three or four days of such treatment would have made nearly every blossom set. Dry, briskly-moving air, no matter if cold, as long as the thermometer does not descend below 27°, is most necessary to the setting of Apricot blossoms. Just let us imagine the hills of the Caucasus, "the mountains there to the top being covered with Apricot trees;" and let us picture to ourselves a March day there, when the Apricot trees are in the full glory of their blossoming—a dry, cold, biting wind, with a bright sun, and the air full of the impalpable pollen dust. The same, or nearly the same atmospherical state must exist on the northern coast of Africa and the slopes of the Atlas, where the Apricot is so abundant. Well, is it not our duty to give our Apricot trees, when in full bloom, a humble imitation of the climates in which they succeed so well?

As to the effects of frost on the blossoms of Apricot trees, it is, when the trees are under glass, of much less consequence than moist stagnant air, and I can illustrate this very pointedly. Last July I happened to be looking into one of my hedge-houses, those most useful structures. In one of them, with a Beech hedge for its back wall, about 8 feet in height, and the same for its front wall, about 4 feet high, I found some bushes of Moorpark Apricots in 13-inch pots: these were placed there for the pur-

pose of producing ripe shoots early in the season for budding. The borders in this house in spring were dust, for they had had no water for six months. To my surprise I found these trees full of fruit, so much so that a tree only 18 inches high had on it two dozen. This led me to look into the matter so as to account for their fertility, as I felt assured that they must have stood in a very cold, windy, dry place; as the trees had had but little water, owing to these houses being a long way from the house, and had thus been partially overlooked; and as it was thought necessary to give them a soaking of water only when they commenced growing, the fruit being a matter of no import, for the houses were open to the numerous boys working in the grounds.

I found on referring to my journal the following memoranda taken when the Apricot trees were in full bloom in April last:—"April 12th, cold and dry. 13th, ditto; frost severe, thermometer registered 24°. 15th, frost severe; thermometer at 23°." Now, in these hedge-houses the temperature in a frosty night is never more than 2° above that in the open air, and often only 1°; so that we have Apricot blossoms in a dry airy place sustaining at least 7° of frost without injury. I need not enlarge on this simple fact—it bears out all that I have ever said about the necessity of giving Apricot trees while in bloom constant air and abundance of it. A neighbour of mine is now so satisfied of this, that he declares his potted Apricot trees shall be placed out of doors daily in dry weather while they are blossoming, and even all night if the weather be mild, removing them to the house only when the nights are frosty. Apricot trees in orchard-houses, as soon as cultivators will cease to take "too much care" by keeping their houses closed while the trees are in bloom, will be held in higher estimation than many other kinds of fruit—they are so beautiful in their blossoms and foliage, and their fruit is of such high excellence.

There is something droll in my friend Pearson recommending us to water the blossoms. If we wish the dust to fly we do not water our roads: *ergo*, if we wish the pollen to fly and "be as dust" we must not water the flowers of our Apricot trees. But doubtless he has some good reason to urge for the practice.

In referring to the habitats of the Apricot I omitted to mention that Dr. Hooker, when travelling in the lower ranges of the Himalayas, and Morecroft, who travelled to a great extent in the far east, found Apricots so abundant in the hilly districts as to form an article of food for the inhabitants. Reasoning from analogy, and from my experience here, I am inclined to dry culture for the Apricot under glass.—THOS. RIVERS.

CHRYSANTHEMUMS.

In the excellent article on Chrysanthemums by "D., Deal," is a sentence which, if not corrected, would lead many to suppose that the Chrysanthemum was not thought very highly of by the patrons of floriculture. The sentence I mean does not emanate from "D." himself, but is what he quotes from the "Proceedings of the Royal Horticultural Society," that because so few persons went to the Gardens on that day the wisdom of not having a Chrysanthemum show was patent.

I, as an exhibitor, can only say there were three or four times as many visitors as I expected to see, thinking that a dull November day would only draw the members of the Committee and the few exhibitors. I was, however, agreeably surprised, and the interest taken in the few plants and cut flowers was evident to any observer. At large exhibitions I have never noticed the flowers and plants more severely criticised, the ladies especially taking great interest in them and carefully inspecting the whole. The writer of the sentence in question evidently drew a wrong conclusion in comparing this small meeting with an exhibition.

I would ask, Was not the Fruit and Chrysanthemum Exhibition of November, 1861, a decided success? I, as well as many others who grow Chrysanthemums, object most strenuously to the sentence quoted, and if not contradicted it might lead many persons to suppose that a Chrysanthemum Exhibition is not a source of attraction, or that the growth of this popular flower is declining; whereas every year brings an accession of cultivators and exhibitors. The Crystal Palace exhibitions of this flower were always well attended, taking the season into consideration, and I think, in a pecuniary point of view, were not unsuccessful. In the present year I hope to see both the

Royal Horticultural Society and the Crystal Palace Company again holding Chrysanthemum Exhibitions. If they do not, Stoke Newington will still be loyal and hold its seventeenth annual Exhibition, and this is still equal to any.—H. W.

STRENGTH OF LIQUID MANURE.

I SHOULD feel much obliged, and I think many of your readers would be so too, by some correct and minute information as to the use of liquid manure, say for pot Vines. All agree that to use it too strong is an evil, and if too weak it may be of no appreciable advantage.

Now, taking Peruvian guano as a manure of most general suitability and known average strength, what quantity of guano should be dissolved (so far as it will dissolve) in four gallons of water to make a solution sufficiently weak to use freely twice a-week? Or, would it be better to use a still weaker solution three times a-week? in either case allowing the intermediate waterings to be from soft water.

For convenience last summer I stirred-up 6 lbs. of guano in about a hogshead of soft water, diluting the solution as I used it. But during the warm weather a considerable fermentation took place, which must have materially altered the chemical conditions of the various constituents of the guano; but whether for the better or the worse I cannot tell, and should like to know. I think this is worth consideration, for it is certainly much more convenient to use a bowlful of a strong solution with each pot of water at the time of using than to be continually mixing-up fresh parcels of guano and water.—PAMPINUS.

[The subject has received a considerable amount of attention. For four gallons of water we should consider three ounces of guano quite strong enough for pot Vines. In fact, we would prefer two ounces. If mixed long beforehand, the barrel should be covered. You will find varying the manure useful—as half a bushel of soot to a barrel, a bushel of sheep-droppings to a barrel, and if fermented all the better.]

For Vines in pots we know no artificial manure more easily applicable than superphosphate of lime. You may put an ounce of this over the surface of the pot and pour the water over it, and put another ounce on in a fortnight: it will do no harm. The same quantity of guano put on the surface-soil of a pot would be apt to kill the plant. Except when we use guano, which we rather prefer keeping dry before using it, we prefer all other manures to be in solution for some time, and to reduce them in strength as we use them.]

HORTICULTURAL SHOWS IN THE NORTH OF IRELAND.

ALL horticultural exhibitions when well conducted by those who take upon themselves such responsibility, are a source of pleasure, not only to those who pay their admission fee at the entrance gate and are exclusively bent upon sight-seeing, but also to the gardener, who with all his care, toil, and anxiety, has watched the progress of his plants and fruit for many long anxious weeks. He is most delighted, not only in viewing his own productions, but likewise the productions of his more successful neighbour, whose success only stimulates him to further exertions. But when I assert that these exhibitions are frequently conducted (in this part) on principles which in the end must prove most prejudicial to their success, I am giving an opinion founded upon observation.

These exhibitions ought to be of an open character, and not conducted, as they too frequently are, upon a principle of exclusiveness. I will briefly illustrate this by examples from this district.

Being desirous of advancing the interests of horticulture in my immediate neighbourhood, I wrote to a friend in the town where the Show was held, desiring him to pay the annual subscription requisite to entitle me to exhibit a collection of fruit, which my noble employer most willingly allowed me to take. The friend in question took my subscription to the Secretary, who refused me permission to exhibit my employer's property in my own name, as he (my employer) was not a regular subscriber. When I heard the decision of the Committee I thought such proceedings most unfair; but when I examined the report of the Show a short time afterwards in the newspapers, I was not at all surprised at my exclusion, for two of the Committee-men (gentlemen's gardeners), received nearly the whole of the

principal prizes! Now, the advancement of horticulture must be quite foreign to this Society's views, otherwise such a display would have never occurred.

At another Show nearer home, in which my noble employer takes a most lively interest, and to which he desired me to send all I possibly could to make the Exhibition as attractive as possible, I forwarded a rather extensive collection of both plants and fruit, naturally expecting that I should be allowed to compete in all the fruit classes; but I was doomed to disappointment in only being allowed to take one prize in a class: however inferior any dish or collection might be, that actually was awarded the second prize, in comparison to those against them. I consider this a most obnoxious rule, and the sooner it is expunged from the Society's schedule the better for its interests.

This same Society had a rule to the effect that all prize fruit was to be the property of the Society when the Exhibition closed; but what gardener, I should like to know, would venture to exhibit his employer's produce with such an outrageous rule as this in force? Why not claim all the prize plants? the Committee would then be able to furnish their greenhouses economically. The worthy Secretary of this Society does not consider the gardener in the least entitled to the puny awards in the shape of prizes; but forwards them all to the gardener's employer, thus leaving the exhibitor no alternative but to pay all the expenses out of his own pocket, which is no trifle when some of the exhibitors have to convey their plants a long distance by water, and be from home three days and nights. I wonder how you southerners would endure such mismanagement as this.—A PRACTICAL GARDENER, Ireland.

BEATON'S GOOD-GRACIOUS DOUBLE BEDDING PANSY.

THE long-lost Double Purple Pansy has been frequently alluded to in our columns, and was figured and described in the "Florist and Pomologist" of December last; but that our readers may form a correct idea of this highly ornamental plant, we have now the pleasure of giving them a representation of its appearance. The stock of this plant is in the hands of Messrs. Carter and Co., of Holborn, who have given it the name of Beaton's

Good-Gracious Double Bedding Pansy, by which appellation we trust it will become as generally known as it deserves. The outer or guard petals of the flowers are about the size of a good Pansy, and the inner gradually diminish towards the centre, forming a double flower. There can be no question that it will form a valuable plant for beds and borders, more especially as we understand that it has proved a profuse bloomer.

LENGTH OF HOT-WATER PIPING REQUIRED FOR HEATING.

CAN you kindly inform me whether two lengths of three-inch pipe (each 9 feet), one flow, and one return, would heat a small pit for stove plants; the pit being 10 feet long, 6 feet wide, 4 feet high in front, 6 feet high at back? And how much larger could I have the pit, supposing four-inch pipes to be used?—A. B. C.

[If you use no covering for the glass you need about 40 feet at least of piping for such a stove-pit; if four-inch pipes the least you could have would be about 30 feet.]

A FEW WORDS TO YOUNG GARDENERS ON EDUCATION AND ATTENTION.

If gardeners are still wanting in intelligence, it is not because enough has not lately been said of our evident deficiencies, of the knowledge we ought to possess, and of the education which the young especially ought to receive. It is quite possible to have even too much of a good thing. A man may starve in the midst of plenty. The labourer, who uses well his few volumes may have more intellect and wisdom than his neighbour who possesses a large library. The very range and the extent of accomplishments and attainments may so dwarf the intellect as to render it unfit to concentrate its force on any definite object: nay, the very extent of the fields traversed, if we have not obtained enough of knowledge to show us our own great deficiencies, will have a tendency to make us self-sufficient, and lead us to look over or condemn the simpler elements of knowledge. Talk of gardening being a learned profession as much as you please; make that learning if you will the groundwork for the social elevation of gardeners, but forget not that some acquaintance with the higher departments of science will prove no compensation for the want of unremitting attention, the want of concentration of purpose to devise, and of activity of hands and feet to execute. That concentration is seldom thoroughly gained without a substantial grounding in the simpler elements.

I was much pleased in reading the other day some statements made by Lord Littleton, when distributing the awards at the Midland Institute at Birmingham, as, after reviewing the studies of the candidates in languages, mathematics, the sciences, natural philosophy, &c., his lordship expressed a hope that such an extended range would not prove detrimental to the acquisition of the very humble but very useful arts of spelling and writing correctly; and added, to strain the intellectual faculties of youth is like beating out gold into gold-leaf—in gaining a larger surface strength and solidity are lost. So much was this the case, that it is no uncommon thing to find young men crammed to examination-point in many of the learned ologies, and who yet fail to succeed because unable to read, and spell, and write their own language with anything like ease, correctness, and elegance.

I would respectfully leave it to those who may have even better opportunities than myself of judging, to say whether, as respects these rudimentary elements of education, a number of young gardeners have not great reason to improve themselves, and that before troubling themselves much with higher branches of knowledge, which, without a good grounding in these elements, cannot prove to them sources of much pleasure or profit. So much do I feel on this matter, that could my opinion have been of any influence, I would have joined that party in our parliament which lately insisted that the obtaining of public money for assisting education, should be greatly dependant on the proved proficiency attained by the pupils in reading, writing, and arithmetic. I should have done this, not only because these fundamental elements of a good education were often comparatively neglected from a preference being given to what was more showy and superficial, but also because I have a strong conviction that, to preserve the sturdy independence of the English character, the assistance given to education should be confined to these elements, and then allowing the parent or the pupil to pay for themselves for whatever is wanted in addition; and this all the more, because equally convinced that the girl and boy that can read, and write, and cipher well, hold in their own hands the keys that will enable them, if disposed, to open all the locks to the great temple of knowledge.

There can be no question, that gardening as an art and a science has made great improvement in this country, and chiefly

through the intelligence and industry of gardeners. It is just as unquestionable that with a few exceptions there has been no corresponding improvement in the social position of gardeners. This matter has been pretty well ventilated in previous volumes; and though pressed to suggest some remedy by many who feel they are sinking deeper in a quagmire of difficulty and find they cannot help themselves, I candidly own I can see no effectual remedy.

A thorough grounding in the profession—a certificate of apprenticeship, journeymanship, and foremanship have been insisted on; and also examination by competent persons, and diplomas to be given according to supposed proficiency, have all been recommended as means for elevating the profession, and all have more or less been tried by leading nurserymen, the Horticultural Society, &c., and with little or no avail. In this free country we cannot prevent any man calling himself a gardener; nor can any restraint be put upon a gentleman as to who he is to employ. It matters not, though the employer suffers greatly in the end, and his cheap servant turns out a very expensive one. The very frequency of such cases glut the market, keeps the apparent supply above the demand, keeps wages down to mere existence-point, and causes many a good gardener, whose services otherwise would be eagerly sought for at home, to starve out of place, or resort to emigration as his only remedy. And yet with all this nurserymen tell me, that at times when a first-rate man is wanted, they are frequently at their wits' end where to find him!

It may be a satisfaction to our young aspiring friends to let them know as a great secret how it is that professional and general intelligence, united with propriety of conduct, is not more generally relied upon as a test of fitness. It is simply this, that these qualifications alone will not make a good servant. I am as much convinced as I ever was, that the more intelligent a workman is the more likely will he be to do his work well. But I am more convinced than I was at one time, that the extra success obtained by a gardener of extended intelligence, is not quite so much owing to the general knowledge thus gained as to a generalising power, which enables him to bring that knowledge to bear upon practical details, and to give an earnest "attention" and constant watchfulness over the minutiae of these details. No acquaintance with "ologies and graphys" will ever compensate for inattention to these details: hence, the plain plodding man whose knowledge is limited, but thorough as far it goes, and who has a veneration for attention to minutiae, will in general excel the philosopher who thinks such minutiae beneath his notice.

Some time ago, I unwillingly overheard two gentlemen speaking about their gardeners. Said A, "What a philosopher of a gardener you have! he seems to know everything." "Philosopher, indeed!" replied B, "I tell you, I never did such a foolish thing as let old C leave me, and just for a few pounds more wages. Then everything was so nice, and the man so modest and retiring, and respectful to everybody, though somewhat independent withal; and when I had occasion to write to him, he sent me such nice letters, confined so scrupulously to the matters in hand, and so well written that I used to let my visitors see them, and that is how he had so many of my friends after him when there was an inkling he was going to leave me. But for shame, I would give anything to have him back again. You see how I am served, flower-beds weedy and half empty, scarcely anything for the table from out-doors or in-doors; and instead, bushels of philosophy, giving me learned lectures on the causes of failure—failure coming after failure to furnish materials for a fresh lecture, as if my table were to be supplied with long learned words instead of fruit and vegetables; and, then, with all this parade of entomological, and phytological, and physiological, and other jaw-breaking 'logicals,' the few letters I have had show too well he never learned to put a single sentence together in decent English. And as for reading, when, because I had forgot my spectacles, I asked him to read a handbill, I was obliged to shut my ears and run! Philosophy, indeed! He is a crammer, has had his head crammed with a lot of big words, and these I must eat if I like, instead of vegetables or fruit."

Why allude to such a dialogue that might have been heard last autumn beneath the arcades of Kensington? Not to depreciate knowledge—not to damp the aspiration of the young gardener to study and render himself as intelligent as he can—but to show clearly that, as a gardener, this knowledge will be of little use to him unless combined with attention to the smallest practical details; nay, further, that unless this attention is seen to be generally associated with great intelligence,

that intelligence alone will not become as many desire it to be—a test of fitness and suitability on which employers may depend.

So much has of late years been said on the education of gardeners—so many are the sarcasms levelled at us because we do not know this, or are ignorant of that, that really it is high time not to attempt to draw the winds out of the sails of knowledge, but quietly to inquire whether these sails are distended with the breezes of Common Sense, or the sweet zephyrs of Romance. When knowledge in such circumstances is looked upon, not only as a power which will ever bring its own reward of pure and elevated pleasure, but is also regarded in its utilitarian aspects, Common Sense comes in and asks, What temporal benefits, what increase of comfort, what social respectability are to be gained by this increased intelligence? Are we to go to the afflicting details that come before the Committee of the “Benevolent,” or to the still more harrowing details that come so often before respectable nurserymen, and those gardeners somewhat comfortable in their position, for a too true answer to the inquiry? As an act of honesty, I would wish to strip gardening as a trade of much of that mere feeling of romantic interest which lingers around it, and advise young men to look at it in its stern realities.

Through that feeling of romance, and the statements so frequently made as to the necessity of a first-rate education, many well-educated youths enter upon gardening with the full confidence that they will gain some of the few prizes that are to be obtained. And so no doubt they would if they waited for them, and combined their extra intelligence with attention to practical details, as some of our best men will tell you, but with the addition that they saw, when too late, they might have taken their education to a better market. I know myself estimable young men, who, when the romance of the affair was gone, and when they calculated the smallness of the returns in wages they were likely to receive even if successful, have entered upon a fresh employment after being several years at gardening. I have also met with many other highly-educated youths who would have made a good show at an examination table, and yet did not succeed extra well as gardeners, merely because they trusted too much to their intelligence, and considered attention to practical details a secondary matter. Of course there is no absolute or natural necessity for this, quite the reverse; but that the circumstances too often exist admits not of a doubt.

Unpleasantness, too, is often the result. A gardener will often speak highly of the general conduct and the polished education of a youth, and yet own that, for attention to a specific charge, or performing the common operations of gardening, he is not so much to be depended on as a common garden labourer. Misconceptions are thus too apt to exist, the polished young gardener imagining that his chief duty is to observe and note as much as he can, with as little soiling of his fingers as possible; and the worthy, old-fashioned gardener, considering that he would neither be honest to the young man himself, nor yet faithful to his own employer if he did not insist on good workmanship and attention, and those who take such highly-educated youths as apprentices or improvers, would do them an act of kindness by giving them a good spell at first among the stokeholes and dunghoops. If they could not stand that without wincing, the sooner they entered upon a more congenial employment the better.

Upon the whole, then, unless there is a particular inclination in that direction, a thorough resolution to make nothing of difficulties, to pay attention to all minutiae, combined with the resolve, as matters now are, to be satisfied with very small remuneration for their talents, I would advise highly-educated youths to take their talents to a better-paying market than gardening. And I do this the more, not because valuing intelligence less as the great means of improvement, but because the field would then be more open for improving the position of those in a humbler class of society, and who had received only the elements of a common education, but who resolved that no want of attention to minutiae, no want of self-denial and earnest attention to study and self-culture, should unfit them for holding a good position in their profession, and a higher position in society than their fathers did. With but few exceptions, from such a class the most successful, the most contented, and, so far as knowledge was brought to bear on professional subjects, the most intelligent gardeners have come.

I allude to these latter ideas, because there is a vast difference

between the comfort enjoyed by a man who feels he has improved his social position, and that of a man who feels he is falling lower and lower, and has never obtained what he considers his deserts. The youngest, if they have followed me, will be in no danger of considering with a friend of mine, that I am at all opposed to highly-educated gardeners, though I insist so much on attention to trifles. “Is it likely,” said he, “that we should have had such instructive writing from Donald Beaton if he had been a stranger to a classical education?” “Is it likely that your old friend Mr. D. should have taken such few steps from the bothie at S. to the superintendence of a gentleman’s large estate, being equally at home in the building of a mansion, and the erection of a conservatory, but for his good education?” “But, for the same advantages, is it likely we should have been honoured with a Sir Joseph Paxton?” and so on with many of the chiefs in the profession.

In all such cases I am not so far a-field. The education did something; the concentrated attention to everything entrusted to their care, the self-denial, and the never-intermitted self-culture, did far more. Mr. Beaton has told us something of his young days in the Highlands, and his troubles in parsing Virgil, &c., and we know something of his never-ceasing self-denial and self-culture in the Lowlands. To such studies, far more than to his Latin, was he indebted for being able to write the reviews of Herbert’s “Amaryllidaceae,” and become a foremost man ever since. The same talents, energies, and self-denial, would have led to success in any field of science and of commerce; and, in the latter, wealth and position might have been gained had such been objects of ambition. I rather think that Mr. D. did not know much of the classics, but he had received a good sound education—could take plans, draw, and reason out a problem of Euclid. With such advantages was he contented? No! never was there a more zealous student. I often regret I was not influenced more by his example in that respect. It is a great mistake in young men to imagine that they must obtain influence and patronage to succeed. I do not suppose that Mr. D., even in the common acceptance of the word, solicited such influence, but he secured it from those with whom he came in contact by his never-ceasing efforts at self-culture, his readiness to oblige, his courtesy of manners, and his faithful attention to everything confided to his care.

Of the younger days of our honoured knight in gardening I know little for certain. There are many current reports in Hertfordshire as to how he worked and studied. Some time ago I chronicled seeing the bed on which he slept in the bothie at Woodhall. There may be something of popular exaggeration, but that distinctly points to Sir Joseph as a self-made man—the result chiefly of long-continued self-culture.

To highly-educated youths who resolve upon gardening, notwithstanding the plain truths I have placed before them, I would say, If you wish to be successful consider no attention and no trifles beneath your notice. To the larger class, who think little except of six o’clock, and how they may get away and spend their evenings in what they call pleasure, it would be useless to say one word. To those from humbler positions, who have mastered merely the simpler elements of education, I would say, Combine strict attention to details, with constant efforts to improve yourselves in intelligence; and thus, not only widen the sources of pleasure, but secure the ability to retain a good situation when you obtain one. A few simple hints on this self-culture may come before us at a future opportunity.—R. FISH.

THE KEEPING PROPERTIES OF PEARS THIS SEASON.

YOUR correspondent “E. B.,” of Deal, in THE JOURNAL OF HORTICULTURE, page 795, puts a question about the keeping of Pears, and you desire to have information on the subject. If, therefore, you deem the following observations useful I shall feel pleased in having made them.

The spring of 1862 gave as great a promise of an abundant Pear crop as I ever saw. My trees, standard and pyramid, were a sheet of bloom, and great were the expectations of pomologists—in fact, I calculated on being able to show two hundred sorts; but, alas! the rains began to be over-abundant, and the temperature kept so low, that soon the rosy blossom began to pale and fade and to show the white feather—a sure sign that the root-action was not going on as it should have done. The consequence was a weakly set of fruit, which progressed slowly, until

about the size of pigeons' eggs, when a sudden fall of the thermometer nearly denuded the trees. Yet hope was strong; and although a thin crop was left I expected, with a rise of temperature, to have come out strong with those that were left. But one mishap very often follows another; and whilst I was in London in the beginning of August seeing the great Exhibition, a hurricane tore over London, and was felt over a wide zone of country. Even our beautiful Somerset felt the "chilly blast;" and when I reached home, oh! my poor Pears! there they lay in their glory, and there I left them for the birds. A few only now remained, and it was evident that I could do nothing in the show way, so I was content to watch what were left, and to note their daily progress.

The *récolte* came, and I found many sorts had braved every danger, and were brought safe into port. How they have fared since I may now tell. Altogether I saved specimens of about 150 kinds, but many of these were small. The following sorts bore well, and have generally kept well:—

Bergamot, Easter.—Now ripe, two to three months before its usual time; buttery and delicious.

Bergamot, Gansel's (from Pyramid).—First-rate flavour, and kept two months longer than usual.

Beurré Berckmans (Pyramid).—A beautiful and delicious little Pear, just done, Christmas-eve, its usual time.

Beurré Bose (Pyramid).—Large, rich, aromatic, and delicious; just now finished—Christmas, two months later than usual.

Beurré d'Arenberg (Pyramid).—Melting, buttery, and very rich. Ripe end of November, two months before its usual time.

Beurré de Capiaumont (Pyramid).—An abundant crop, fine flavour, and first-rate this season here. Once in two or three years, in my soil, it is worthless. Ripe about its usual time, October.

Beurré Diel.—In my soil always small, and not often second-rate. This season better than usual, and some of the fruit have kept till now. Speaking generally, in this neighbourhood this kind is magnificent.

Beurré de Rance seems keeping well, and I suppose will do so till May by its appearance.

Beurré Duhaume, Beurré Easter, Beurré Gris d'Hiver, and Beurré Langelier have all kept well till now, and have been and are excellent.

Beurré Navez and Beurré Superfin.—The first bore an immense crop, which was very good, and ripened as usual in September; the second was delicious, kept sound, and was ripe in the end of September.

Bishop's Thumb.—A heavy crop. Has been in use during November until now, and very good. Some still remaining.

Bon Chrétien, Williams'.—Was very fine, large, and good. Ripe as usual. One of the hardest Pears known.

Broompark has kept well, and is just beginning to turn ripe. First-rate from my soil.

Calebasse.—Heavy crop. Kept sound, and ripened as usual in October.

Calebasse Grosse.—Very large, and with me very fine; this season extra fine.

Catinka.—A delicious and first-rate fruit here; is just done, its usual time.

Chaumontel.—Not yet come in; seems to be keeping well, beyond the usual time here.

Citron des Carmes.—Bore abundantly this season, and was ripe from the tree in August.

Colmar Neill.—Not good this season; just done two months after its usual time.

Comte de Flandre.—First-rate; has kept good till now, December 31st.

Comte de Lamy.—Immense crop, of which the birds had the greatest share: they know what is good. What they left ripened in November; extra delicious.

Conseiller de la Cour.—A splendid Pear in my soil, and the tree a great bearer, especially upon the Quince. Good till end of November.

Delices d'Hardenpont (Belgique), and Delices de Jodoigne have both been excellent, and have kept over their usual time.

De Trousseau.—Has been excellent here, and it ripened in the beginning of December.

Doyenné Boussoch.—Delicious, and ripened a week after it was gathered, October 18th.

Doyenné Defais and Doyenné Goubault.—Both ripened in December, and are first-rate sorts.

Duchesse de Mars.—Small here this season, but a good crop.

No signs of ripening yet; usual time November and December Delicious.

Duchesse d'Orleans.—Was fine in October, its usual time.

Easter Bergamot and Easter Beurré.—Now both ripe and delicious, the last especially melting and fine. Usual time February.

Figue de Naples.—Not yet ripe; usual time November.

Fondante d'Automne.—Abundant crop, excellent, and ripened in October; later than usual.

Fondante des Charneux and Fondante de Noël.—Both first-rate. The first ripened December 4th; the last is not yet ready. Usual time Christmas—one of the best of Pears.

Glou Morceau.—Delicious, and ripened in November; a month sooner than usual.

Grand Soleil.—Large and excellent. Ripe end of November, about its usual time.

Hacon's Incomparable.—Was ripe in November and very good.

Jamiette.—Not yet ripe.

Laure de Glymes.—First-rate. Ripened in November; usual time October.

Louise Bonne of Jersey.—Ripened about a fortnight later than usual.

Marie Louise.—Kept good until November, and was then excellent.

Monarch.—Bore well this season. Fruit not yet ripe, but looks sound and good.

Napoléon.—Bore well, but the fruit was ripe from the tree in October.

Ne Plus Meuris.—Just beginning to turn soft. Bore well.

Paradise d'Automne and Passe Colmar.—Both good, and just becoming ripe.

Rondelet.—A delicious sort. Ripened in the middle of November.

Seckle.—Some of the fruit kept till November, and was delicious.

Sieulle.—A fine aromatic fruit; kept sound till November.

Thompson's.—This fine Pear ripened in October, a month earlier than usual.

Urbaniste.—This delicious Pear ripened early in October, its proper time.

Van Aesche.—A rich and fine Pear; kept sound till the middle of December.

Vicar of Winkfield.—Is now in eating, and is this season a nice juicy fruit; generally only fit for the cook.

Winter Nelis.—Whilst writing these notes, I have just had some in to taste this delicious and first-rate Christmas fruit. It will continue good for another fortnight.

Zéphirin Grégoire.—This rich, sugary, and delicious Pear ripened here a month ago, being nearly two months earlier than it does sometimes.

Besides those enumerated above, I have still some others not yet ripe; but they are, generally small and inferior to what they should be, and it would not be doing them justice to say anything about them this season, which has not been at all a propitious one. May we hope that the one just arriving may prove more genial? Again, our fruit trees are covered with buds, I think to even a greater extent than last season; and looking over my collection of Pears, three hundred sorts, to-day (January 1), on purpose to report to you the prospects of the coming season, I find very few indeed that are entirely devoid of fruit-buds, and the Cherries, Plums, and Apples in the orchards here look promising indeed.

We have now had four good cider years following, and there is every appearance of having a fifth. I think we must thank the wind for this, as it thinned the crops liberally, giving two advantages to the orchardists—viz., a good crop of finer and better-matured fruit, and also a prospect of a crop the following year, from which I think that "those who run may read" a lesson. Were we to attend more to the careful thinning of our fruits, our trees would not suffer by overbearing, and the quality of the fruit would be much improved, and its keeping properties lengthened-out. Does a Grape-grower expect, when he leaves all his bunches on and his berries also, as is nearly always the case with out-door Grapes, to obtain a crop the next year? We all know that Grape-growing requires extra thinning, and who will say that the same rule ought not to be applied to all kinds of fruit? Were proper thinning and careful root-culture more attended to, we should find the keeping qualities of most fruits much improved.—J. SCOTT, *Merriott, Somerset.*

CULTURE OF THE GENUS BOSSIAEA.

THE BOSSIAEAS are a family of leguminous plants, chiefly from Australia and Swan River, some of them remarkable for a singularly elegant habit of growth, and the whole of them for the very profuse manner in which their flowers are produced. Unfortunately most of them produce flowers nearly of the same colour, and hence they are not so much cultivated in collections as they otherwise would be; but some of the species being remarkably distinct in foliage and habit, and forming, when properly grown, very elegant specimens, are worthy of considerably more attention than they are receiving at the present time. Their cultivation is very simple; the secret of producing fine specimens being that of laying a good foundation, for without that it will be impossible to produce a fine plant. To this end procure, when purchasing plants, the strongest you can meet with in the nurseries. When we say the strongest, we do not mean plants 12 or 18 inches in height with a few branches, but short bushy fellows; and if the collar, or part of the plant just above the soil, is as thick as your finger, and the plant is healthy, and the roots vigorous, you may make sure you have a good plant. It may be remarked *en passant* that the preceding criterion of a good plant may be taken as a safe guide in purchasing plants of all kinds, more especially hardwooded plants; for if they are dwarf and healthy, and have, moreover, strong stems, you may make sure that whether they be large or small, they have been well propagated, and well cared for afterwards.

Having procured such, take some good fibrous turfy peat, such as those who understand plant-growing procure from Wimbledon Common, and after removing the inert soil, or sand, as it is sometimes called, from the bottom, and the coarse vegetable matter from the upper surface, break it into small pieces, and then pass every part through a half-inch sieve; to four parts of this, add one of nice mellow, fibrous, turfy loam, two of gritty sand, and one of charcoal and potsherds, broken to the size of hazel nuts; mix these intimately together, and then they are ready for use. Next procure some clean porous six or eight-inch pots, and drain them thoroughly. If the plants are such as we have advised you to purchase, place the strongest in the largest pots, and the weak ones in the six-inch size, taking care to fit the soil nicely about the roots, and to make it tolerably firm; indeed, if the compost is dry you may make it as firm as you can, without resorting to the ramming process of our forefathers.

The plants should then be placed in a pit or frame, where they can be kept tolerably warm and moist, shading them in mid-day until they begin to grow, and taking care to syringe them and shut them up early every sunny afternoon. Thus treated, they will progress very rapidly, and some of them will probably require a second shift towards September. If a frame or pit cannot be spared to place them in, make the nearest approximation you can to the conditions required, to promote free growth in the greenhouse, by keeping a part of it close; or place the plants in a vinery, or other forcing-house, where the temperature is not too high, and where plenty of air can be admitted in favourable weather. It will be necessary to curb redundant growth by timely stopping the strongest shoots, to make them branch; but in the cultivation of Bossiaeas, unless a branch takes a decided lead, nothing will be gained by stopping it, as they generally, at least the majority of the kinds, produce secondary or lateral shoots in tolerable abundance.

Bossiaea tenuicaulis.

When they are first potted it will be necessary to water the plants with caution, but after they are in free growth, and are well rooted, a good soaking occasionally with weak liquid manure, such as is produced by steeping a bushel of sheep's-dung in a hogshead of soft water, to which a peck of soot and a quart of guano may be added, will be of considerable service. This, diluted with an equal quantity of clear water, will be found excellent for plants of all kinds, providing its use is guided by a practical eye, and too much is not given at one time. As a general rule, if the soil is good, liquid manure should never be used until the pots are tolerably well filled with roots, and under no circumstances to a plant that is in delicate health. To expect to invigorate a sickly plant by giving it liquid manure

would be as wise as to expect to sober an intoxicated man by administering alcoholic drinks: therefore recollect in plant-cultivation, overfeeding is worse than under-feeding, for you may keep a plant alive on short commons, but once gorge the system, and a plethoric habit is induced, and all healthy action is at an end. We make these remarks thus plainly, not only as applicable to this tribe of plants, but to all plants, and to all cultivation: therefore inexperienced persons will act wisely to make a note of it for their future guidance. All the plants belonging to this genus are very subject to the attacks of the red spider, so it will be well to look them over occasionally, and after syringing, if they are affected, dust them over with sulphur, and let it remain for a few days, when it may be washed off again.

Bossiaeas may be propagated by cuttings of the half-ripened wood; but, as they produce seeds very readily, it is seldom necessary to increase them by cuttings. The seed should be sown directly it is ripe in July, and the plants be nursed in small pots through the winter.

In the second year, the established plants may be grown, after they have bloomed, in the open air, taking the same precautions as before directed as to insects, &c., and potting them when necessary.

The following are distinct and pretty species; the engraving represents *B. tenuicaulis*:—

B. cordifolia.—A dwarf-spreading shrub, with terete villous branches, and cordate acute, nearly sessile leaves. The yellow flowers are

marked at the base of the standard with a purple circle, and have a dark purple keel. New Holland. Introduced 1824. Flowers in April and May.

B. disticha.—A dwarf shrub, rather erect in habit, with slender branches, and two-ranked ovate-obtuse leaves. The flowers are showy, on stalks longer than the leaves; the standard is pale yellow, with a spot of deeper yellow at the base, and bordered with red—the wings stained with red at the base. Flowers from April to October. Swan River. Introduced 1838. A variety of this is grown in gardens under the name of *B. disticha plumosa*.

B. ensata.—A singular-looking upright species, with compressed linear leafless branches, toothed along the edges, and bearing the flowers from the notches. The flowers are yellow; the base and back of the standard brownish-orange purple; the keel brownish-purple. Flowers from May to July. New Holland. Introduced in 1825.

B. linophylla.—A small, slender, erect-growing shrub, with compressed branches, bearing linear leaves with the edges recurved. The flowers are yellow, the standard veined at th

TO OUR READERS.

WE know of one who would not have on the parlour chimney-shelf a dial with a second's hand, because it made him see and feel how life lessens, as it were, drop by drop. What he would have said, or how he would have felt, if he had to write these Prefaces surpasses our power of surmise, for they at once tell of six months gone—and how quickly gone!

Grateful are we to record that truth, for miserable is he over whom time passes on heavily. But no such weight has been upon us: no day has been long enough or slow enough—each day's evening seemed to arrive before its morning had passed into noontide.

This was not because there were no sorrows around us; for we have had by our desk refugees from the once United States, telling of homes crushed, and of brother in arms against brother in fratricidal and suicidal war: we have had a blast from that war among our own homes, and our pages have told of one small passage in the wide and deep amount of privation and sorrow which it whelmed over our cotton districts. Death has not been less frequent than usual in his visits among those whose aid we had; nor have we found jealousies less jaundiced, nor envyings less dettractive.

But we have had compensations for all these ills. We were able to give occupation to the unemployed and to point out to others those who deserved assistance. When a chasm occurred among our friends others stepped forward to render the vacancy less observable; and as for the jealous and the envious, we had no leisure for being inconvenienced by them.

Thus have we passed on through 1862; and over its close we will inscribe the hope that from its days our readers, as well as ourselves, have passed on into 1863 wiser, happier, wealthier—wealthier not merely in this world's gear. May its harvest of wisdom, happiness, and wealth be even more abundant than that yielded by its predecessor; and we will include in that prayerful hope our brethren across the Atlantic. Many of our readers are there, and they may accept from us as truth that great is the delusion which suggests that “Britishers wish nothing but evil to America.” If that fiendish desire actuated our countrymen, they would not so earnestly hope that the internecine war waging there may speedily cease.

Heartily do we join in that hope—nay, more, it is the most prominent in a cluster of good hopes, including one for the well-being and well-doing of each and all of our contributors, and another for the vigour and endurance of those so abundantly recording themselves as our “Constant Readers.” May they all be evergreens, and then our concluding wish will be gratified, for we shall all have

A HAPPY NEW YEAR!

INDEX.

- ABIES MICROSPERMA**, 84
Acacia, *Drummondii* pruning, 90; *armata* in summer, 230
Acanthoneura strigosum, 553
Acclimatisation Society, 93
Acer, *palmatum atro-purpureum*, 540; of the Romans, 593
Achimenes, 727; at rest, 618; *Mauve Queen*, 678
Aconitum of the Romans, 702
Acrotrema Walkeri, 790
Adelaide Botanical Garden, 349
"African (South) Economic Flora," 678
Agave glaucescens, 495
Agricultural Society's (Royal) Show, implements at, 254
Agrostemma coronaria, 398
Ailanthus silkworm, 118, 246, 581, 688
Ajuga reptans purpurascens as an edging, 476
Alexander, James, 164
Almeida rubra, 555
Alocasia metallica and *macrorrhiza variegata*, 85
Aloe, about to bloom, 221; family and their culture, 574
Alphabetical arrangement of poultry exhibitors, 772
Amaranthus, melancholicus ruber, 369, 430; *tricolor*, new, 449
Amaryliss—belladonna culture, 55; *Unique*, 143; *belladonna soil*, 166; culture, 479; *blue*, 480; *anica*, 705; *formosissima* culture, 769
Amarylises in pots, 618
American plant, leaves diseased, 224
Ammoniacal liquor destructive of caterpillars, 192
Ammoniacal gas in a hothouse, 490
Amphitheatre of verdure, 455
Anemone, *apennina* culture, 34; *narcissiflora*, 398
Anemones after flowering, 146
Angers, its tree and fruit trade, 745; market-gardening produce of, 783
Angustifolius fragrans as a medicine, 16
Anguria Warczewiczii, 52
Anisanthus splendens, 488
Annals, for edging *Geranium*-beds, 35; select list of, 644
Anomochloa marantoides, 378
Antholyza ethiopia, 488
Anthurium Scherzerianum, 196, 337
Antirrhinum, wintering seedling, 479
Ant-bills, to get rid of, 146
Ants, in *Melon-bed*, 241; in grass, 262; in *Cucumber-frame*, 343
Aphelexis culture, 765
Aphides and their destruction, 176
Apiarian, events of 1861, 17; notes, 18, 423; *Miscellany*, 708, 775
Apiary—"B. & W.'s" in 1862, 129; of "Upwards & Onwards," 731
Apple-trees, heading down, 55; trees cankered, 127; *Irish Peach*, 378; trees unfruitful, 594; trees, vitality in, 714; renovating, 741
Apples—sweating before storing, 83; storing, 302; selection of, 705; keeping, 719; *Ribston and Cox's Orange Pippins*, 761
Apricot shedding its blossom, 127
Apricots—under glass, 223, 240; scale on, 705; in pots in orchard-house, 785
Aquarium—parlour, 235; *Warrington's*, 262; water for, 685
Aquariums, in garden: que scenery, 103, 122, 141
Aquilegia glandulosa, 398
Arabis alpina, propagating, 229
Araucaria, Cookii, 237; not thriving, 704
Arbor Vitæ, cutting American, 495; hedge, 617, 618, 671
Arbutus procera, 84
Archerfield Early Muscat Grape, 451, 457
Architectural features in gardening, 494
Arctotis, new, for edgings, 368; reptans, 407
Argemone grandiflora, 398
Aristolochia Gibertii, 677
Arnott's stove, brick, 726
Arrowroot culture, 94
Artichoke, is it hardy? 668
Artichokes, are they hardy? 716, 725; culture and hardiness of, 744; protecting, 762, 763
Arundo donax culture, 108
Ascidia intestinalis, communis, arachnoidea, tubulosa, and prunum, 452
Ascidians, compound, 436; social, 437
Asparagus—earliness of, 118; beds, mismanaged, 127; culture, 127, 637; ailing, 166; beds, 281, 321; tops, 398; salt for beds, 402; moving, 479; beds, wireworms in, 499; forcing, 578, 724; beds, manuring, 618; bed, removing old, 770
Asphalt, flooring, 540; walks, making, 783
Aspidiotus ostreaeformis, 562
Aspidium Ficus, 437
Athanas nitescens, 399
Atriplex hortensis, 382
Aubrietia purpurea, propagating, 229
Aucuba japonica, male and female, 3
Auricula, Show, National, 10; exhibitors, North and South, 116
Auriculas, in 1862, 83; *George Lightbody* and *Southern Star*, 294
Australia—South, at the Exhibition, 295; *Western*, at the Exhibition, 319
Aviary, birds for, 624
Aylesbury ducks, characteristics, 226
Azalea—its characteristics and culture, 415; varieties, 416; *indica*, cuttings, 108; *Duc d'Arenberg*, 196; *Mars*, 294; *Brilliant*, 495; leaves, insects on, 541
Azaleas—classified list of, 42; list of, 154; in summer, 230; to harden-off, 382; propagating Indian, 685; manure for, 686; in ainery, 726; and liquid manure, 769
Axiu styrinchus, 375
BABIANA RUBRO-CYANEA, 488
Balance the good and the evil, 318
Balconies, management of plants in, 389
Balsams, sowing, 36
Bantam cock, points, 584; hybrid with Pheasant, 584; class at the Crystal Palace, 750
Bantams losing head-feathers, 76; *Duckwing*, 150; *Black cock's* ear-lobes, 150, points in Game, 168; colour of ear-lobes, 266; *Pied*, 599, 665, 666; classes at the Crystal Palace, 600; (Game) classes, 619; food for, 624; *Black*, at *Darlington*, 770, 797; plea for, 772
Basket plants, 302; pendulous, for greenhouse, 705
Baskets for fowls, 286
Bath and West of England Poultry Show, 72, 184
Beauty and utility combined, 220
Bedding-out, 55, 182, 202; at the Crystal Palace, 308; at *Cliveden*, 336; at *South Kensington*, 387; plants, propagating, 457; system defended, 777
Bedding plants—in pots, 146; and the *Derby Day*, 189; supporting, 223; propagation of, 417; preparations for propagating, 438; wintering, 597
Beds, circular, of three kinds of plants, 127
Beech hedge, making, &c., 670
Bee-keepers' perplexities, 234
Bee-keeping—in Cheshire, 110; *Woodbury* on, 129; in *Cornwall*, 167; in *Staffordshire*, 163; commencing, 325; hints to practical, 385, 405
Bee—flowers, late, 304; cells in *Jamaica* not enlarged, 323; season, *Middlesex*, 346; *Gloucestershire*, 346; *Larkspur*, two-coloured, 495; *parthenogenesis* in, 564; season, in *North Lancashire*, 74; in *Devon*, 92; season, *Berwickshire* and *Lancashire* moors, 622; *East Lothian*, 623; *Bee year*, 1862, 709; *Dzierzon* on *parthenogenesis*, 731; apparatus (*Swiss*) in the *International Exhibition*, 753
Bees—in winter, 17; uniting, 20, 37, 364, 443; removing, 38; as chemists, 58, 112, 149; over-feeding, 58, 112, 149; and swallows, 93; early swarm, 93; travelling by railway, 130; death of a queen, 110; cross between English and *Ligurian*, 112; zinc about, 112; attaching combs to bars, 149; winter management, 149; feeding, 149, 346; queens, destroying, artificial swarming, artificial comb, and milk as food, 150; deserting their hives, 187, 226, 245, 442; do they vary? 207, 225, 242, 284, 463, 642; queen destroyed by workers, 207; swarming, in a storm, 225; season in *North Lancashire*, 243; tithed, 226; present season; death of a queen; hybrids; as chemists, 265, 305; Who ascertained first the sex of queen? 266; do they make honey? 284; settled facts about, 286; *Ligurian* queens, 304; in *Jamaica*, 305; *Ligurians* not irascible in *America*, 305; fumigation, deserting hives, 305; losing a queen, 345; misfortunes of season, 345; *Ligurian*, 385; queen from worker-egg, 404; fumigating, 405; introduction of a *Ligurian* queen, 423; artificial combs for, 423; practical observations on, 423; queen mutilated by workers, 424; transferring and uniting, 442; living in a frame-hive, 442; transferring, eggs not hatching, 463; abandoning hive, 482; foresight of, 483; in *Staffordshire*, 484; varying in their proceedings, 501; in smoky places, ejecting eggs, chloroform for stupifying, 502; and bee-hives at the *International Exhibition*, 583; queens becoming drone-layers; queens assailed by own workers, 544; queen's fertile age, 601; do workers become fertile? 604; using embossed wax, 604; queen's age of fertility, 623; longevity of working, 643; fertile workers, 643; hybrid *Ligurians* "B. & W.'s" apiary in 1862, 665; deserting their hives, 688; fertile workers, queen drone breeding, 774; bottle-feeder for, 776; in buildings, 798
Beet, Red, as a border plant, 592
Begonia prismatocarpa, 52; *fuchsoides* culture, 748
Begonias, propagating, 55
Bejaria coarctata, 277
Belladonna Lily culture, 779, 795
Berberis japonica, *intermedia*, and *Bealii*, 146; *aurahuacensis*, 256; *Wallichiana*, 698
Berberidopsis corallina, 677
Bessera elegans, 488
Beverly Poultry Show, 203
Bird question, 298
Birds, and the crops, 124; utility of small, 151, 175, 219, 283; protection of in *Switzerland*, 196; why they should be protected, 200; destruction of small, a plea for, 256, 258; spare the, 315, 318; uses and destructiveness, 536; migration, 538; mischievous, 576; small, &c., 660; use of, 636; balance of, 681; cause pleaded, 792
Bird's Nursery, 625
Birmingham Rose Show, 63, 180, 272
Birmingham Poultry Show, 619, 638, 706, 727, 729; pens at, 520; Exhibition week, 640; Judges at, 664, 688
Bishop's weed, 146
Blackberry, *Lawton*, to train, 412; wine, 504
Boiler, adapting a stove to, 55; for vinery, 617; at back of parlour fire, heating by, 705; *Clarke's*, 767
Boilers leaking, 35
Bois de rat, 61
Bolbophyllum rhizophora, 52; cupreum, 196; *pavimentatum*, 378
Bone-crushing, 15
Bones and potash, 55; dissolving, 281
Borders, good form of, 764
Borecole, report on varieties, 293, 314
Boronia serrulata culture, 64
Botanists, meeting of workmen, 271, 318
Potrychium lancifolium, 553
Botryllus, 437
Bottle-feeder for bees, 37, 58
Bougainvillea glabra culture, 218
Bouquets, 493
Bowling-green, size of, 541
Box-edging, management of, 88; destroyed by salt, 183, 238
Box ledge, making, &c., 671
Brahma Pootras, 776; merits, 38; hens as layers, 464
Bridgesia spicata, 712
Brisbane Botanic Garden, 589
Broccoli, *Carter's Champion*, 142; manured with sewage, 158; moving large, 638
Broccoli, report on, 333, 374
Brodiaea grandiflora, 489
Brugmansia leaves yellow, 363
Bryanthus erectus, 277
Bucket, *Holmes' self-tilting*, 786
Bulb-bed to flower throughout the year, 498
Bulb (Cape) culture, 778
Bulbs, *Cape*, 368; for out-door planting, 488; management of spring-flowering, 508; in pots, 509; care in testing, 527; out-door, 561; in beds, 573; rare, 638; vegetating strongly, 747

- Bullfinch-paralysed, 544
 Bullfinches' eggs disappearing, 345; 385; Black, 776
 Bupleurum fruticosum, 712
 Butter, large yield from one cow, 38
 Butterflies, killing for specimens, 286
 Buxus obcordata, 4
- CABBAGE—SOWING AND PLANTING, 351; caterpillars, 581; Jersey Sticks, 490
 Cabbages, report on, 492
 Caladiums in winter, 541
 Calampelis scaber culture, 34
 Calavansa Bean, 99, 123
 Calceolaria—leaves spotted, 54; history, &c., 120; as a bedder, 120, 136; cuttings, 561, 625; planting, 634
 Calceolarias—wintering, 480; shrub-ving, 609; cuttings, 617; for exhibition, 638
 Californian orchards, 613
 Callianassa, Underground, 375
 Callistemon brachyandrum, 535
 Calne Poultry Show, 619
 Calocaris Macandrews, 375
 Calochortus pallidus, 515
 Calves—fattening, 38; rearing on milk and linseed meal, 188
 Camellia—and its culture, 59, 169, 261, 445; watering, 59; seeds, sowing, 168; list of varieties, 170; propagation, 267; Contessa Lavinia Maggi, 294; seedlings culture, 322; flower-buds breaking, 562, 618; buds falling, 747
 Camellias—in summer, 230; cross-breeding, 332; recently grafted, 598
 Campanula Vidalii, 615
 Canaries—diseases of, 19; selling, 38; mortality among, 38, 283; in a room, 58; model prize list, 73; dying, 584
 Canary—and British Finches, 73; cock eating eggs, 150; hens sitting without laying, 185; sick, 688
 Cantua buxifolia, 657
 Cape Gooseberry culture, 281
 Carex Fraseri, 36
 Carnation—characteristics and culture, 47; varieties, 48; tree, culture, 756; list of, 757
 Carnations—tree, culture, 71; striking, 382; sowing, 439
 Carrot—grub, 281; crop failing, 587
 Carrots on clay soil, 302
 Carter & Co.'s Nursery, 156
 Caterpillars—on fruit trees, 139; venomous, 246
 Cat, destructive, 305
 Cats v. birds, 219
 Cauliflowers—under glass, 107; protecting, 560
 Caution, 299
 Ceanothus genus, species described, 21
 Celery—turnip-rooted, 34; culture, 239, 280, 517, 725, 789; grubs on, 241; roots, 261; leaves brown, 479; fly, 587; culture in Lancashire, 592; white-leaved, 598; growing and failure, 655; fly, preventing its attacks, 700; failure this year, 744; how to grow good, 762; failures, &c., 788
 Cells, formation of royal, 482
 Cement walks, making, 784
 Centaurea—candidissima, 518, 691, 795; propagating, 229; cuttings, 519; argentea as an edging, 742
 Cephalotaxus Fortunei, 51
 Cephalotus follicularis culture, 562
 Cerasus—japonica flore pleno culture, 71; ilicifolia, 712
 Cerastium—tomentosum, propagating, 16; frosted, 71; Biebersteinii, 127, 367, 425; for flower gardens, 45, 84
 Cerastium, tomentosum and Biebersteinii, 129; treatment of, 402
 Ceropegia Gardneri, 52
 Charcoal—as manure, 370; making, 701
 "Chemistry of Soils, Handy Book of," 142
 Cherry—blossoms falling, 70; Trip-leton, 90; Nouvelle Royale, 143; trees, winter-pruning young, 748
 Cherries—on walls, 240; falling, 281
- Cheshire Poultry Show, 542
 Chickens—large brood of, 128; noise in throats, 306
 Chinese Primrose, Double-flowered, 196
 Chinese Primroses, Delicata and Rubra grandiflora, 378
 Chippenham Poultry Show, 730
 Chiswick, Royal Horticultural Society's garden at, 372
 Chiton cinereus, &c., 558
 Chlidanthus fragrans, 489
 Chloride of lime as an insect-killer, 177, 250
 Christmas, poultry market, 770; time, 794
 Chrysanthemum—culture for show, 82; notes on, 647, 650; at Mr. Salter's, 652
 Chrysanthemums, 625, 779; twelve superior, 16; list of, 780; management of seedlings, 727
 Cinchona, trees introduced into India, 606; plants, introduction of into India, 659
 Cineraria maritima—cuttings, 14, 34, 540; seed sowing, 70; propagating, 498, 748
 Cineraria flowers not opening, 685
 Cinerarias—preservative from green fly, 93; compost for, 224; James Andrews, The Artist, and The Winner, 378
 Circumstantial information, 451
 Cissus discolor, growing specimen of, 11
 Clarkia, White-margined, 678
 Clavelina lepidiformis, 437
 Clay soil, to improve, 581
 Clayey loam, lightening, 769
 Clematis—viticella venosa, cutting down, 84; lasuginosa, hardy, 770
 Clerodendron—Thomsonae, 143, 175; culture, 514
 Clethra arborea, 402
 Clivanthus Dampieri potting, 499
 Climbers—for conservatory, 127, 480; in verandah, pruning, 254; for a greenhouse, 421; for an arbour, 580
 Clipped trees, effect of in decorative gardening, 453
 Clomocoma montana, 52
 Clonmell House, 81
 Clover, four-bladed, 164
 Clusia Brongniartiana, 294
 Coal tar for vermin, 791
 Cobaea scandens seedlings, 223
 Coburgia incarnata, 488
 Cobwebs, 457
 Cochlin-China cock, cold in, 688
 Cochlin-China fowls—falcon-hocked, 246; vulture hocks in, 286
 Cochlin-China pullets—not laying, 20; combs, 326
 Cochlin-Chinas—points in, 366; Cin-namon, 624
 Cockscumb culture, 56
 Cockscombs, sowing, 36
 Cocoa-nut fibre refuse, 381, 426, 480; for seedlings, 15; as a manure for flowers, 16; mixing soil with, 55, 146; for drainage, 218; for peat, 231; for cuttings 241; as a general manure, 272; for Cyclamens, 281; and clay soil, 769
 Cœlogyne Parishii, 293
 Coix lachryma, 362
 Coleus Verschaffeltii, 190; as a bedder, 134, 158; for bedding, 809; culture, 727; hardy, 795
 Collingham Poultry Show, 621
 Colour, theory of, 134, 196, 300
 Coltsfoot, Sweet-scented, culture, 785
 Columbia, British, botanical expedition to, 451
 Comb foundations for hives, 524
 Combs—crooked, 366; artificial, 604
 Conclusions, too hasty, 298
 Concrete walks, making, 784
 Coniferae—propagation of, 410, 463; notes on some hardy, 742
 Conifers, propagating by cuttings, 780
 Conservatory—climbers, 202; plants for back wall, 598; heating a small, 738
 Cooking old fowls, 282
 Coop for chickens, 604
 Coriaria sarmentosa, 712
 Cork refuse, 52
 Cornwall—weather and crops, 118; market-gardening in west, 577, 595, 612, 636, 659
- Coronillas in summer, 230
 Corydalis nobilis, 398
 "Cottage Improvement Societies," 279
 Cottingham Poultry Show, 441
 Cotton—seed refuse, 30; spinners, Lancashire, 333; plants, soil for, 706
 Cow—management, 11; keeping, 504; dried before calving, 710
 Cows, 732; in Guernsey, management of, 644
 Crabs—Common Shore, Velvet Swimming, Arched Fronted, Cleanser, and Marbled, 234, 235; Dwarf Swimming, Henslow's, Common Pea, Angular, Pennant's, and Circular, 294; seashore, 334, 359
 Cramp—in goslings, 363; in fowls, 666
 Cranston's patent horticultural buildings, 6, 101
 Crasula coccinea, propagating, 303
 Craven Poultry Show, 462
 Crenella marmorata, 516
 Crève Cœur fowls, 206
 Cricket-ground, grasses for, 479
 Crickets, destroying, 705
 Crium capense culture, 769
 Crocus—Imperati, 5; the genus, 114, 135; bulbs, treatment of, 402; speciosus, 526; bulbs, saving from mice, 770
 Crocuses, saving from mice, 581
 Crossing flowers, 348
 Crow—and farmer, a fable, 306; family, the, 404

base with red, and the wings and keel marked with the same colour. Flowers from May to September. New Holland. Introduced in 1803.

B. rhombifolia.—A small-spreading shrub, with the branches terete, and the branchlets compressed, bearing rhomboidal-orbicular leaves, somewhat emarginate and mucronate. The flowers are yellow: the standard with a zonate red mark at the base, the base of the wings red, and the keel brownish-

purple. Flowers from April to June. New Holland. Introduced in 1822.

B. tenuicaulis.—A pretty twiggy shrub, with round, slender, straggling branches, and sub-sessile ovate-subacute mucronulate leaves. The flowers are yellow; the standard marked with a zonate blotch of red at the base, the wings streaked with red, the keel dark red. Flowers in April and May. Van Dieman's Land. Introduced in 1836.—(*Gardeners' Mag. of Botany*.)

GAS-HEATED BOILER.

HAVING seen many inquiries made about which is the best way of heating small greenhouses, I send you a sketch of my small patent gas boiler. It is formed of seven tubes, with a ring of jets of gas beneath. There are seven small burners, one fixed exactly under the centre of each tube. The boiler is made of copper, and is 12 inches high by 9 inches in diameter; and

the water space is between the tubes upon the same principle as the locomotive engines. The whole is enclosed in a sheet-iron case just the shape of the boiler, made to fix on the top and extending down the side nearly to the bottom. This case confines the heat to the outside of the boiler, and to prevent the cold air getting between this casing and the boiler a flange is fixed.

In the above drawing, A A are two cast-iron boxes about 9 inches long, and of just sufficient width and depth to admit of an inch-bore pipe being screwed into them. The top one, of course, forms the flow and the bottom one the return. B is another box which answers for the return; C is a small air-tube; D the supply-cistern, which may be placed wherever most convenient so long as it is above the highest point of the pipes, which should be the box B; and E is where I generally put in the supply-pipe, which need not be more than three-eighths of an inch thick.

You will observe from the sketch I have four flows and four returns, the surface of which is a little more than two rows of four-inch-bore pipes; for the circumference of a four-inch-bore pipe is about $14\frac{1}{2}$ inches, while that of four one-inch bore pipes is better than 16 inches. Sometimes I put only three rows, and sometimes only two, just according to the size of the house. F is a slide for lighting the gas, which can be opened and shut at pleasure. There is a tap for drawing the water off at any time. H is a two-inch sheet-iron tube for carrying-off the burnt gas.

This boiler may stand in the greenhouse and the flue-pipe be taken through the roof, or, what is better, if practicable, put into a chimney-shaft. This boiler contains about three quarts of water.

If you refer to your No. 90, at page 738, you will find an inquiry and a remark made that two three-inch pipes should be used; and as regards heating surface no doubt the remark is quite right; but, as a practical engineer, I must beg to say that neither two nor three-inch pipes ought to be used for gas, if economy is to be considered. Supposing, for example, the circumference of a three-inch pipe is 9 inches, 1 foot in length would contain 84.82 cubic inches of water. Now, if we use three one-inch pipes instead of one three-inch pipe, we obtain the same heating surface, and have only 28.27 cubic inches of water to heat: consequently a great saving in gas is effected. I use to my gas boilers one-inch-bore wrought-iron pipes. Sometimes I put as many as four flows and four returns, just according to the size of the house.

I can guarantee my small gas boiler to keep the frost out of a greenhouse 20 feet long by 15 feet wide for something like 3s. 6d. to 4s. per week. I have several fixed in Liverpool, and some in Scotland; some have been at work ever since this time last year, and have been also fixed in the house without any injurious effects whatever. In short, that is impossible, as all the burnt gas is carried off.—T. C. CLARKE, *Eagle Foundry, Liverpool*.

AMERICAN ICE-HOUSES.

ICE can be kept in large quantities during the whole summer season in houses built entirely aboveground; but where it is desired to have a preserving-chamber, and to insure a sufficiently low degree of temperature to attain good results, it is indispensably necessary that the earth should be banked-up to the height of several feet against the outside of the building. In constructing my ice-house, I took the advantage of a convenient and descending spot, sunk a pit 15 feet by 18, and from 4 to 5 feet deep; walled it up to the height of 9 feet, banked the earth up to the top of the wall all around, except a space for the doorway; upon the wall I put a frame 6 feet high, which gives a height inside from the bottom to the comb of the roof of over 20 feet. I put heavy sills in the bottom, except in a space 4 feet square for the preserving-chamber. Upon the sills I put a floor of two-inch oak plank, and on the top of this a floor of one-inch pine jointed closely. The floor has a descent of 2 inches

towards the preserving-chamber, and it conducts the waste water from the ice to this chamber. I put it in an inside frame, and lined it inside; this left a space of 6 inches between the lining and the wall to fill with sawdust, and the partition between the ice and preserving-chamber is also double, and filled-in with sawdust well packed.

To complete the preserving-chamber, I first put in clean sand to the depth of 4 inches, then paved it with medium-burned bricks, they being preferable to hard, on account of their capacity to absorb and retain a large amount of water. Pains were taken to have the floor exactly level in one direction, and also very tight, so that all the waste water from the ice shall be conducted to and distributed regularly upon the bricks. This keeps them so constantly cold as to preserve milk during the hottest season for from thirty-three to thirty-six hours perfectly sweet, and keeps butter very hard. One valuable feature belong-

ing to this mode of preserving milk and butter is, that during the warmest weather of summer season, when cold, sweet milk, and butter of a degree of solidity equal to that of the winter season, are appreciated as two of our greatest luxuries, we can have them so, from the simple fact that at that particular time the supply of cold ice water is greatest.

Butter made and kept in this way does not become so soon soft after being brought to the table, as that which has been kept in a spring of water, nor do thunderstorms appear to hasten the development of lactic acid. We have noticed no perceptible difference in the length of time which the milk has remained sweet, in regard to clear or stormy weather. I have observed at different times, by placing the thermometer within a foot of the bricks in the preserving-chamber, that the temperature was about 54°, while it was 95° in the shade outside. The sand underneath the bricks subserves an important purpose, by retaining the water, and supplying it to the bricks by capillary attraction at such time as there is not a great supply coming from the ice.

The space above the preserving-chamber should be open and unobstructed to the roof, and over the ice there should be good ventilation to the roof, to carry off all the vapour which may arise from the milk.

An ice-house constructed in this manner is one of the best investments for a farmer, for besides securing the luxury of preserving milk and butter cool, vegetables of different kinds may be preserved fresh until a succeeding crop grows. I kept one year's Beets good till the following summer; also Cabbages. These latter I laid upon the ice, which imparted to them a crispy sweetness, perfectly delightful in the very warm weather of June. Vegetables may also be preserved in this manner by farmers, so as to bring them fresh to the market in early summer. —(*Canadian Agriculturist.*)

PRESERVING ICE IN AN ICE-HOUSE.

THE ventilation adopted by "AN ELEVEN-YEARS SUBSCRIBER" I think was not so much at fault as the quantity of ice put together. Twenty loads of ice, when pounded, would not make a larger bulk than ten loads or tons of Potatoes. Probably no ice-house in the three kingdoms could keep twenty loads of ice longer than he states. Fifty loads of ice are about the smallest bulk which most gardeners would like to trust to for a season's supply; but just double that quantity, or very near it, is the more usual amount, and I have put 160 loads in one heap in the open air, and found it not too much for a daily run on it from the beginning of July till ice came again. It strikes me a "return" of the quantities of ice stored by a dozen or two of our leading gardeners, who have to keep up a large supply, would be an excellent guide for a right understanding of this question. About fifty loads are the smallest quantity I ever saw put together. I often put from seventy to eighty loads together, sometimes 100, and on several occasions 150 loads. —D. BEATON.

BOILERS FOR GARDEN STRUCTURES.

HAVING observed in one of your Numbers of December last a few remarks from Mr. Legg, of Tranmore, relative to the merits of Clarke's new patent boiler as compared with those of the old saddle-back boilers, allow me to offer some observations in corroboration of Mr. Legg's statements, as I have had considerable experience in the management of saddle and similar boilers for some years, and latterly of Clarke's new patent. Like Mr. Legg, I too opine that those who are in favour of saddle or similar boilers are not aware of the merits of Clarke's, one of which has been under my care for more than twelve months past, and I have found it exceed my most sanguine expectations.

About fifteen months ago my employer wished to have erected a new vinery, and, at my suggestion, on the rafter principle, 50 feet long by 15 feet 6 inches wide, to be divided into two houses—in connection with an old but still good metallic vinery and succession Pine-house combined, 43 feet by 17, which was heated by one of Thomson's retort boilers. This was considered incapable of heating effectually the three houses collectively: consequently it had to be removed for one of greater power. As I was permitted to select any kind of boiler that would meet the requirements, owing to the apparently superior construction of Clarke's

new patent, I at once applied to Mr. Clarke, of Liverpool, to furnish us with one of his smallest-sized boilers, with piping, taps, &c. I now find it takes less fuel to heat the whole range than what the retort boiler took to heat the whole vinery, and with fully one-third less attention, which latter I attribute chiefly to the efficiency of a very ingeniously-contrived deflecting flue-plate or hollow top, in thoroughly concentrating the heat. It is truly, as Mr. Legg observes, a capital amateur's boiler, and, I may add, also for where extensive ranges of glass are required to be heated on the one-boiler system, as, in addition to the above merits, a duplicate would not be required to assist it; and it possesses strength of material, great power, and rapid heating capabilities.

In conclusion, allow me to add that I hope shortly to prove its further capabilities in heating an early Peach-house, 36 by 15 feet, by the same boiler.—W. GARDINER, *Eatington Park, Stratford-on-Avon.*

COVERING HOT-WATER PIPES.

You will oblige me much by advice how best to obtain bottom heat in a pit lately completed, having one four-inch flow-pipe above in front, and four four-inch return-pipes side by side below, like a table or counter, 3 feet from the glass.

I put a foot of cocoa-nut refuse over the return-pipes, yet though they are so hot that I can hardly bear my hand on them below, the refuse above them is as cold nearly as the garden border.

Would tan bark above the return-pipes, a foot thick, allow the heat to reach pots plunged in it properly?—J. M.

[You could scarcely have a worse conductor of heat than the refuse tan would be. For cleanliness we prefer small stones for a foot, and sand to plunge in; but coal ashes do admirably. In such cases we generally use stones, and then surface with anything most convenient. We have just half the number of pipes for giving bottom heat to a Melon-pit, and the earth generally becomes warm above the stones in a couple of days, and retains the heat then.]

DUNG FERMENTING ON A VINE-BORDER.

I HAVE covered a Vine-border with fresh stable-litter laid on at various times during the last two months, and find that since the last layer was put on the whole of the covering has fermented very much, and is now hot. At the same time a stake, pushed through it into the earth of the border, is not much warmer than the air at the lower portion of the stake. Can you tell me if the heat being so considerable at the top is likely to injure the roots of the Vines? The border is well drained, and has an open trench in front. I am about to commence heating the inside of the house.—A READER.

[You must judge for yourself, according to the depth of the roots. It is as well that the soil should not be warmer than from 70° to 80° where the roots are. If the roots, however, are a foot from the surface they will take no harm, though the heat on the surface of the soil should be as much as 85° or 90°. If the course is persevered in you must be more careful of the extra heat every year, as the roots will get nearer the surface. If you find the heat is too much where the roots are, reduce the covering. The bottom of a long trial-stick is no guide; regulate your proceedings by the heat indicated by a thermometer where you expect the most of the roots to be. Many Vines have had their roots burned when a strong heat was applied, and the roots were near the surface.]

GISHURST COMPOUND.

THE paragraph at page 14 of your last Number of the Journal, speaking of Gishurst compound, makes me venture to send you the enclosed extract from a Melbourne newspaper received only the day before yesterday. The writer, an influential amateur horticulturist, was unknown to me until he wrote me the results of dressing with Gishurst on his and his neighbours' Orange and Apple trees. "The zeal and enthusiasm of the inventor" has never gone so far as Mr. Carson, who, speaking as he found, and unconnected with Gishurst except as a purchaser and user, has for nearly three years constantly held up the virtues of Gishurst. I believe it is a medical rule that medicine is best studied where

the disease is most virulent. Mr. Carson's account of the Australian blights, unchecked as they are by winter, makes our English ones appear insignificant.

From having been some twenty years among chemical experiments, I have had some practice in watching results; and yet must confess that the Gishurst action sometimes fairly puzzles me. That it does more than soap, and sulphur, and tobacco, and any combination of all or any of them, I have heard and seen too much to doubt; but to obtain the full action on trees at rest strong solutions must be used, and then some care must be used not to injure the buds.

For several years past I have made it a point of honour to dress all my own trees with either a stronger or more thorough Gishurst washing than I recommended, and I never gave them any after-waterwashing, so that any injurious action might be at once perceived.

Early last month I very thoroughly drenched my trees with a solution, eight ounces to the gallon, laid on by means of a large painter's brush. One portion of the trees had the solution, fresh from the box, used directly it was dissolved; another portion had it dissolved forty-eight hours before, as recommended. Yesterday, on carefully going over the trees, I found that Apples, Nectarines, Cherries, Peaches, Apricots, are all crowded with their fast-swelling perfectly-healthy buds and the Plums quite untouched; but some of the Pear-buds are browned and will fall. Now the trees seemed all at rest when the solution was applied. Some of the Pear trees have not a bud injured, others a few buds, others a large proportion. Last year—and I doubt not a similar result will obtain this—increased vigour in the buds left made the trees bear as much fruit as was good for them to carry; but the result of this second year's experience would lead me in future to recommend not more than six-ounce applications (unless followed by a waterwashing) to Pear trees, even when at rest.—GEORGE WILSON.

Extract from a paper read in the Athenæum, Kew, by Mr. Carson.

"But, fortunately for those now about to plant, about three years since Mr. G. Wilson, of Belmont, having a desire to free his sister's Roses from the aphid, discovered a most effectual remedy that is now sent out under the name of Gishurst compound, at a cheap rate, by the company that he is connected with, and can be so prepared and applied as to meet every case of attack from any of the insect tribe, and with not the slightest injury to the trees. The benefit this invention has been to the gardening world may be conceived when I state that the year it came out I had made up my mind to root-up all the Orange trees and put them in the fire, for all our spare time did not suffice to keep them clean.

"At this time I was burning my blighted Apple trees, and lately I have been told by several gardeners that they had condemned their Apples when they learned from me of this cure. But for this the axe, they said, would have settled blight and trees together."—(*The Yeoman and Australian Acclimatiser* 27th Sept., 1862.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHERE a systematic rotation of crops is carried out it is an excellent plan to trench all the kitchen garden successively in the course of every three years, the trenching to be performed each year to be on the ground intended for tap-rooted plants—such as Carrots, Parsnips, &c.; also in laying-down new plantations of Strawberries, Raspberries, bush fruit, &c., if the sub-soil is stiff and sour it should be left at the bottom, and a good coat of cinder ashes worked in amongst it, which would serve to facilitate the passage of water and the admission of the atmosphere. Beans, Broad, sow some Longpods to succeed the crop sown in November. Carrots, sow Early Horn on a sloping bank thoroughly prepared for the purpose. Peas, sow a good breadth of any of the early sorts to succeed the November sowing. Potatoes, Ashleaved Kidney and Early Manly may be planted on a warm border; sets of these may likewise be planted in small pots for the purpose of being forwarded for planting-out in the open ground.

FLOWER GARDEN.

As the weather is mild the planting of trees and shrubs may be proceeded with, as may also the pruning where pruning is

necessary. This is a good time to lay new turf, or repair turf edgings. See that all half-hardy plants are secured against severe weather. Regulate herbaceous plants, reduce Phloxes, &c., where they require it, and replant them after well digging the ground; take care not to plant too thickly, and leave room for more tender plants in summer.

FRUIT GARDEN.

If Vines on walls have not been already pruned the operation should be no longer delayed. Protect Figs, if not already done. The method generally adopted is to unnaill the trees, tie them in bundles together, wind some straw ropes around, and cover them with mats. Regulate the heads of Filbert trees, and remove suckers.

STOVE.

This is a good time to prune and regulate the heads of the specimen plants. Many—such as *Justicias*, *Poinsettias*, *Aphelandras*, &c.—had better be cut down altogether, and kept dry for a few weeks; if the stock of *Euphorbia jacquiniæflora* is large cut down some of them also, which will enable them to make an early growth, and, consequently, come into flower earlier next winter. Look at the *Gloxinias* and *Gesneras* on the dry shelves, and set a few roots of each into growth to produce a succession of flowers.

GREENHOUSE AND CONSERVATORY.

The conservatory should present a gay appearance now if the forcing-pit has been well supplied. Examine daily every flowering plant, remove every decaying flower as it appears, and see that the foliage of *Camellias*, *Rhododendrons*, *Oranges*, and similar plants is perfectly clean. The contrast produced by the fine, clean, large leaves with the numerous blossoms at this season especially gives increased interest to the houses, and renders them doubly capable of yielding enjoyment. Keep the *Pelargoniums* in the greenhouse in a quiescent state, give as little water as possible—in fact, none, unless the plants show a disposition to flag in the leaf. Abundance of air is requisite, avoiding, however, cold currents, which are very liable to spot the leaf when in a tender state through close confinement. Keep *Cinerarias*, *Heliotropes*, *Calceolarias*, and all softwooded plants in the lightest part of the house and as near the glass as possible; *Correas*, *Epacrises*, *Heaths* to be placed on a bench by themselves in the most airy part. This is a good time for collecting the droppings of deer, sheep, and stall-fed oxen; these and such like manures as can be procured should always be had in store.

FORCING-PIT.

The principal point to attend to here is to keep the temperature, with a moderate supply of moisture at 60° at night. Let the maximum be 65°; and to keep up the supply of such plants as can be forced successfully, and be made available in the conservatory either for decoration or perfume, bring in Persian and common Lilacs, Azaleas, both the hardy and Chinese sorts, Lily of the Valley, Hyacinths and other bulbs, *Acacia armata*, *Epacris*, hardy and Nepal *Rhododendrons*, *Daphnes*, *Deutzias* and the early sorts of *Pelargoniums*, *Roses*, &c.

PITS AND FRAMES.

Examine your stock, and such plants as you are short of should now be placed in a gentle heat for the purpose of exciting their growth for cuttings—*Verbenas*, *Petunias*, *Salvias*, *Heliotropes*, *Ageratums*, *Pelargoniums* of sorts, and all other such plants for filling beds and borders in summer. Prepare soil for potting-off store pots. Auriculas require great attention just now. Care must be taken to remove decayed leaves, the surface-soil to be kept stirred, and the plants allowed all the air possible, bearing in mind that drip or too much moisture at this season is their destruction. Polyanthus to have all trusses of flowers removed, if good blooms are to be expected at the proper season. Tulips are peeping up, and will require to be covered on frosty nights with mats or hoops placed across the bed. Carnations to have all the air possible; if they are well established and of a fine glaucous hue they require but little attention in comparison with those that have been potted late; bricks to be put at each corner of the frame, raising the woodwork at least 4 inches from the ground to secure good ventilation. Ranunculus-beds to have a dressing of old cowdung and old leaves slightly forked-in preparatory to planting in February. Examine Pink-beds, and where the pipings have been raised by worms they must be carefully fastened. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

ATTENDED to vegetables as mentioned last week. Took up more Sea-kale and Rhubarb. Gave all the air possible to Radishes, Lettuces, and Asparagus under glass, the two-light frame of the latter still furnishing excellent cutting. See the mode of packing in a previous Number. "HECTOR" says he has very little from a two-light box; but, no wonder—he had placed his old lump of roots as thinly as he would put Cauliflower plants in a quarter. According to his own account a quarter of a light would have held all his roots and not been much crowded. There is nothing gained by thinness in such a case, as the roots are of no more use after being forced, and, therefore, the less room they occupy, provided the buds have free opportunity to lengthen, the better. It is this fact of the uselessness of the old roots after forcing that makes Asparagus so costly in winter. The great advantage is, that the soil from whence the Asparagus is taken is fit to grow anything else afterwards. To obtain Asparagus in November and on to the 1st of January, all things considered, I question if there is any mode more economical than taking up part of an old bed and packing the roots closely over a bed of dung and leaves. But circumstances must alter treatment. For instance: here is a "LOVER OF ASPARAGUS," who writes to say, "I have little ground for kitchen-garden purposes. I am anxious to have Asparagus after Christmas—say about the 10th of January, but if I succeed I must have the plants to bear continuously, and though I have sufficient litter to give enough of heat, I must have that litter concealed. I could use at that time five sashes 5 feet long and 4 feet wide, and I have wooden covers to match the sashes. What had I better do?" The best plan for you would be to have Asparagus-pits, either raised above the ground or mostly sunk beneath it, if there is no danger of water lodging. Suppose the last to be the case, I would fix on a suitable place and mark out two pits 21 feet in length and 8 feet in breadth, with a six-foot space between them. These eight-foot widths I would excavate to the depth of $2\frac{1}{2}$ feet. The outsides I would slope a little from top to bottom, and keep all tight with brick on bed, leaving a little more than 18 inches for lining. The centre space would be a brick pit, the wall pigeon-holed until you came near the level of the ground. The front wall might be a couple of courses above that level, and the back wall four courses or five, which would give a slope when the sashes were put on. Now, inside of that pit I would fill-in 15 inches of any rough boulders or clinkers, to secure effective drainage, and also admit the heat freely from the linings. On the top of this I would have 15 inches of good loamy soil two parts, and the other parts of equal proportions of drift sand and sweet leaf mould. On that I would plant two-year or three-year-old plants rather thickly, and as soon in the spring, and not before, as the plants had grown a couple of inches in length. These should be watered and shaded a little at first, and top-dressed with rich manure surfacings and manure waterings several times during the summer. A little hot dung in the linings until midsummer will cause them to come strong the first year and ripen early, and will thus produce a gathering the next season, though it would be as well to wait until the following year. I am supposing that both pits are treated exactly alike. I am also supposing that fillets are placed on each side of the lining, or that $1\frac{1}{2}$ inch of brick has been left out all the way along to receive wooden covers, about 6 feet long, which will thus conceal all the dung.

Well, the first season it is designed to force the Asparagus the heads should be cut down as soon as the foliage becomes yellow, the bed be cleaned, forked-over a little, some fresh mulching with a little salt added, and then covered-up with either the sashes or wooden covers to keep drenching rains from the bed. About the middle of November fill the linings half up with hot dung and leaves, and cover with the boards, and in a few days water the beds with manure water at about 100° . In a fortnight fill up the linings. As soon as the Asparagus is a couple of inches in length endeavour to use the glass sashes to secure greenness. By this time the second bed may be slowly excited, and the wooden covers would do for that until the glass could be spared from the first bed. By using these beds as the first alternately, and giving rich manuring during the summer, these beds would continue bearing a great number of years, and, if anything, be yearly becoming better. Much would depend on the free growth in summer and the early ripening of the shoots in autumn. I have often resorted to a medium mode between

such established pits and taking up the plants, by having some beds well raised in the open garden, with alleys 18 inches deep between them, filling these alleys with fermenting dung and then covering that with straw, and either laying loose sashes across the beds or setting hand-glasses on them. I have also obtained a gathering a fortnight before the usual time, by setting four-inch flower-pots thickly over the beds as soon as the shoots began to peep above the surface, with a tile over the hole of the pot. In sunny weather the heat inside the pit caused rapid growth. In a frosty night some litter sprinkled all over kept the shoots all right.

For some years I found blanched Swedish Turnip-tops rather liked in the winter months, but my man says they seem not to be much cooked now. In severe winters, however, they would be very useful in many circumstances. We can have as many as we like by merely sticking the tubers in a little moist earth or litter in the Mushroom-house. Any place averaging from 50° to 60° of temperature would produce them in great quantity. No doubt they would be good green, grown in light; but I think they are richer when yellow from having been grown in the dark. The head should not be above 6 or 7 inches in length before it is cut; and if not longer, the Turnip is not much injured for cattle.

Potatoes, started in small 60-pots, have been transferred, three plants to a 12 or 15-inch pot, and two to a nine-inch pot. The pots were drained, half filled with light loamy soil containing a good portion of leaf mould, and the plants, each with one stem, placed close to the sides and the pots filled-up to within 1 inch of the top, pressing the rather dry soil firmly about the plants. If left loose these will grow as well if not more freely, but they will not tuber so well.

FRUIT GARDEN.

Proceeded with nailing and pruning as the weather would permit. Looked after insects which have not quite left the Peach trees in pots. Removed all traces of decay or shrivel from branches of late Grapes, keeping the house empty and dry, and a fire every damp day. Rather more than half of the house being cleared, contemplate pruning and clearing that portion, keeping a cloth between it and where the fruit is, and then cram it as well as every other place with plants. Placed some Strawberries in vinery from a frame where they stood for several weeks, on a hotbed, not plunged in it. Put a few more leaves in the frame to bring the bed nearer the glass, and filled that again with Strawberry plants, standing on the surface so as to be coming on for the Peach-house, which now, with the exception of 1 foot of path, is crammed above and below with bedding plants, but these will be removed as soon as the buds swell. All the air possible is given, unless on frosty nights, as we do not want the crop so early this season. No black fly or beetle have appeared since the smoking, washing, and painting of the shoots. When painting the shoots is resorted to, be it Gishurst, some combination of sulphur and clay, or even clay and soot alone, I think it important that this should be done as long as possible before the buds break. Washing just as they are swelling fast, can be of little use for keeping insects and their eggs shut up from the air.

Put in a fortnight ago a number of Vine-cuttings in a mild hotbed, and moved them to a warmer bed to encourage quicker growth. There are many ways of treating these cuttings or buds. Perhaps the oldest is as good as any. Take a shoot, or shoots, of the Vine to be thus propagated; cut it into as many pieces as there are good buds, leaving about a space of 1 inch on each side of the bud, thus making the cuttings 2 inches long. The two ends may as well be cut clean across. This is all that is really necessary in making the cutting of well-ripened wood; but, in addition to this, I generally slip off a thin shaving on the side of the cutting opposite to the bud, so that more liber and albumen are exposed. Then, taking a number of six-inch pots well drained, and filled to within 1 inch of the top with sandy loam neither wet nor dry and pressed pretty firm, the cuttings are placed somewhat thickly with the shaved part next the soil, pressed rather firmly, and, with the buds thus uppermost, I cover them with half an inch of sandy soil. If the pot is plunged in a hotbed and covered over with a saucer, there will be no necessity for watering until the buds are appearing. When great nicety is necessary, as when it is required to fruit the Vines from these cuttings the following year, the cuttings should be separately put into small pots, and then the roots receive little or no check in potting. Removed the Vines in pots that

were placed in a frame with a bed of leaves and horse-droppings, into a pit where a little fire heat could be used, because the frame being in a rather shady place and the weather so dull, no moderate amount of air would enable one to dry the Vines, but the moisture and damp hang to them—a matter of no moment for the first few weeks, but which might have injured the buds as they were swelling.

ORNAMENTAL DEPARTMENT.

Here, too, pruning, planting, digging, and clearing have been generally practised, along with leaves-gathering. Conservatory plants were looked over. In stove, small plants of Ferns and other things repotted into aired heated soil. Pelargoniums were smoked with tobacco and capsicums—Scarlet Geraniums especially; Variegated were potted separately; and Verbenas, being very thick in 60 and 48-pots, were repotted into 32-sized pots, or several plants put into a 16-pot. Before doing this, as there were a few whitish marks, respecting which it was doubtful whether they were white smears or might be mildew, and as, though I did not see any, I was rather suspicious that there might still be some vestiges of thrips left, a bucket was filled with sulphur laurel water, and, turning each pot with the fingers across the soil, pulled the heads of the plants several times through the solution, and then, to prevent the latter finding its way into the soil, laid the pots down on clean litter on their broadsides. After remaining there half-a-day, each potful was syringed round and round with clear water at about 130°, and the pot watered so as to make sure of every fibre being moistened, and thus to be ready for shifting the following day. The soil used was light and rich; and though the small pots had been nearly half-filled with crocks, all were left in, and the roots not disturbed. After potting, the pots were plunged in a leaf-bed with a kind gentle bottom heat; but in all such mild weather the tops will have plenty of air. From what I have seen take place with Verbenas I have a reason for every one of these minutiae. One friend says, "Why not pot-off the Verbenas singly?" Well, this I never like to do until the middle of the month and in favourable circumstances; but as to finding room for a tithe of such potted-off plants I might as well attempt to fly. The little bottom heat at first after shifting will cause vigorous root-action. The plants can be shaken-out afterwards for earth-pits if we think proper; but our chief object is to have plenty of stubby short-jointed cuttings a month or six weeks hence. I have several times stated how to make sulphur lime-water: a gallon bottle of it will last ever so long.—R. F.

TRADE CATALOGUES RECEIVED.

W. Cutbush & Son, Highgate, London.—*Catalogue of Select Vegetable, Flower, and Farm Seeds for 1863.*

Plymouth Seed Company, Plymouth.—*General Price Current of Kitchen-Garden, Flower, and Farm Seeds.* 1863.

J. Illman, Wellington Place, Strood, Kent.—*Catalogue of Stove, Greenhouse, Hardy Exotic and British Ferns.* 1862.

TO CORRESPONDENTS.

LOBELIA SEDLING (J.O.).—The two plants are now in most beautiful health in Mr. Beaton's omnibus-pit. They seem much easier to keep than speciosa, and would make a gardenful of plants by next May were they propagated to order. One of the plants flowered in September, and was not then nearly so good as the same style of seedlings was at the Crystal Palace; but it was too late in the season to judge properly. They will not be propagated, but will have a fair start in a clergyman's garden, and Mr. Beaton will report on them in August.

BUDDING FORCED ROSES (P. Brentwood).—Your plan is founded on scientific principle, and your plan and theory are both correct, and must succeed; but, after all that, the practice of the whole trade is against you. We shall enlarge on this question next week.

GOURDS ON POLES (Adolphus).—One of our regular correspondents has grown them on poles for the last two years, forming a series of arches across a central walk in the kitchen garden; but he thinks, from the short time the plant and its fruit remain ornamental, they hardly deserve the trouble they give. A pear-shaped and a fig-striped one were about the most ornamental in a dozen or twenty varieties; but they sport very much. The best eatable varieties are the old Vegetable Marrow and the Custard. We have heard of others being wholesome, but not so agreeable as these. We cannot undertake to recommend nurserymen; and such a sporting plant as the Balsam is always prone to furnish single-flowering plants from seed of the best double.

FARFUGIUM-LIKE CYCLAMEN (T.).—We are requested by Mr. Beaton to say that a customer comes forward, who will give a fair price for the Cyclamen with the leaves blotched like the leaves of Farfugium grande, providing Mr. Beaton can assure him that the leaves are really so marked. If "T.'s" friend will, therefore, send a leaf to Mr. Beaton, it will be sent back by return of post if "T.'s" friend wishes it.

HIPPEASTRUM EQUESTRE CULTURE (H. M. K.).—There were two kinds of it from the West Indies, one with larger flowers than those of the other. It is the most difficult of them all to manage, owing to its "singular constitution." Naturally, it is not prone to expend itself in making offset bulbs like your plant. You cultivate it like *alicum* and that race, otherwise your tale would be different. *Hippeastrum equestre* should lie dormant, in a dry place in the stove, from the end of October to the beginning of April, and then be watered until the plant flowers, or until the leaves are at their full length—say by midsummer. From that moment, from the flowering, or from the leaves attaining their full length, it is a hardy greenhouse plant, and in July and August would do better out of doors than in any house; but by the end of August it ought to be on a high back-shelf in a greenhouse, be watered till the end of October, and then turned into a stove and water withheld, soon after which the leaves die down.

SPAN-ROOFED GREENHOUSE (J. Buckley).—It is purely a matter of taste and economy as to whether you have a house made with rafters and moveable sashes, or a fixed roof. Where much heat is not required, you may give air by the moving of the front upright sashes; where much fire heat is wanted, as in early vineries, it is a great advantage to admit air close to the warming medium. With sashes, you could have the upper ones to slide. With a fixed roof, with three-inch rafter-sash-bars, you had better have a double ridge, with a foot ventilator between and a cowl outside, as Mr. Cox airs his houses at Kilmington; or, as you seem to contemplate a stage in the middle of the house, that ventilator could be drawn along from the ends, as is done by Mr. O'Brien, at Mr. Bewley's, near Dublin, or by Mr. Niven, for front air, at Drumcondra, which we presume you have noticed. In a fixed roof, the supports will do well. Of course there is a bar on each side the whole length of the roof, against which these posts abut. In a sliding roof with rafters, no posts would be necessary. For a greenhouse alone, the height of 12 to 14 feet would be ample in your exposed place. The higher you go the more room for the Vines, but the more exposed it will be. We would have the two ends pointing north and south.

CENTAUREA CANDIDISSIMA (J. C.).—We have just seen ten plants of *Centaurea candidissima* in No. 16-pots in a nursery, and the way followed there would suit you and all other nurserymen. A dozen were bought last year for stock; they were planted-out, and were too late for autumn propagation; they were lifted, and put into the big pots at once, and in the beginning of December they were put into a gentle forcing-house—say into 50° of heat at night, and on the second day of the new year we saw them just on the move; and we advised an old practical hand to have all the centres of the heads of the plants to be stopped, by twisting a piece of wire down the centre of each division of the heads, and that stopping will increase the suckers and side shoots tenfold for cuttings. Our friend had done the Pine Apple suckers long since on that plan, stopped them, and put more strength into the fruit—a better plan, he said, than teasing a good fruiter by tearing-off so many suckers.

CATERPILLAR (T. F. R. C.).—It is a caterpillar of the Noctuidæ, and most probably of *Noctua uncinulosa*, the Angle Shades Moth. This caterpillar had been very destructive of our correspondent's Begonias and Cinerarias.

EVERGREEN-BED (B. B.).—As you have Rhododendrons already, and wish a graduated rise in the evergreen-bed from the edging of Roses, the best plan would be to plant the first row of *Andromeda floribunda*, about 10 inches or a foot high, and a foot from the Roses, and make the bed of different sizes of *Berberis aquifolium*. After a bed of one high colour of Rhododendrons, a bed of this *Berberis* is the most telling evergreen-bed that has yet been made. Mind, the Roses must be Chinias and kept very dwarf, otherwise the effect of the bed is soon ruined.

BEETROOT EDGING (A Constant Reader).—Our correspondent asks "Will Beetroot make a good edging to *Calceolaria floribunda*, or can you give me a better?" Beetroot would make a good edging to any of the bedding plants; but the question is, who would like it save a farmer, and he would find a much better use for it.

BEDDED GERANIUMS (Idem).—Christine, edged with Mangles', would be more telling than Bijou or Mountain of Light, or any of the other variegated Geraniums, or all of them put into one bed could be with an edging of Mangles', and for this reason—that there is no contrast and no combining of tints, when a bed of variegated plants is edged with a variegated plant of the same kind as that in the bed.

LIST OF BEDDING GERANIUMS (Idem).—There are two kinds of Alma Geraniums as bedders—Mr. Dennis's large purple perpetual of the greenhouse class, and the variegated Alma. Both these are the very best in their respective sections, and both of them are less miffy, to a certainty, than any other kinds of equal merit in their strains. The best dwarf Nosegay Geranium is Baron Ricassoli, and "D. Deal" puts it first in the lists of last year. But to decide which is "the best" of anything in "gardening" is a futile attempt, for tastes differ. However, we shall enumerate the good, the better, and the best, according to our liking after a while.

COCOA-NUT FIBRE DUST (W. H. T.).—A hundred times we have said that this refuse is *dust*, more like brown snuff or mahogany sawdust than anything else, and you send us a bunch of hair-like fibres and ask us if that is it! Such fibres will do to cover pot-drainage, but for nothing else. (T. B. M.).—This is the right material, though not so fine as it is usually.

PAINTING WITH GISHURST COMPOUND (W. P.).—The painting of the walls, &c., of a Grape-house and orchard-house with Gishurst compound could do no harm if done now, so that the strong scent would be gone before the buds swelled; but, unless there is some particular reason, we do not see much to improve in the plan. If the walls were full of holes and insects, then it would be desirable.

MULCHING AND WATERING VINES (Idem).—When to do so is too indeterminate, and depends, especially watering, on the time you wish them to grow, and if dry or moist at the roots. Mulching can do no harm at any time. Night soil, either liquid or otherwise, should be used in small doses. Last year we knew some fine young Vines ruined, because their owner imagined nothing could be too rich or too gross for them.

CAMELLIA FLOWERS DEFORMED (An Inquisitive Under-Gardener).—When plants are very healthy, the appearance you complain of—the flowers defective, or twisted on one side—is often the result of the centre of the ball being left dry, or too much water remaining from defective drainage; in either case the root-action being deficient. If neither of these is the source of the disappointment, it would be advisable to tie a woollen thread round the buds when swelling freely, to keep them from splitting.

SEEDLING CINERARIAS (*W. H. M.*).—They are good border varieties, but there are many better.

NAMES OF FRUITS (*Wm. Godsal*).—Fondante de Noël. (*J. B. E.*).—1, Cockle Pippin; 2, Dumelow's Seedling; 3, Keswick Codlin; 4, unknown; 5, Lewis' Incomparable; 6, Grange.

NAMES OF PLANTS (*C. G., Stafford*).—*Pilea muscosa*. It belongs to the natural order Urticaceae, and the Linnaean class and order Monocia Tetrandria. (*B. J. S.*).—The plant is known as *Celosia pyramidalis aurea*, really a feathered variety of yellow Cockscomb—that is to say, a sport which has taken the opposite direction from that of the great flattened "combs" more usually grown. (*Katey Did*).—The specimen of the plant which grows so abundantly on Clee Hill, Shropshire, is *Lycopodium clavatum*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE KENDAL POULTRY SHOW.

THE eighth annual Show of this Society has just concluded, quite eclipsing all the preceding ones; and it may now be deemed fairly established as belonging to the best of our local meetings. This gratifying result has, however, not been attained without a hard struggle on the part of its projectors. In the first place the Kendal Show has from time to time been subjected to many difficulties, simply from the trouble of obtaining a room at once sufficiently large, and at the same time properly lighted, wherein the Exhibition could be held. Various were the successes on this score; and at one time so much difficulty arose in this respect as to cause the meetings to be discontinued altogether for two consecutive years. At length, however, the affair has assumed a far more exhilarating aspect; in short, this year the necessity of the case has worked its own cure. To the astonishment of the Secretaries, they found the accumulated entries made at the time specified for closing them were about twice as many as those of former years; and the question that stood supreme to all others was, first to determine in what way so extraordinarily increased an assemblage could by any possibility be accommodated. The happy thought occurred to them, that if they could obtain the use of the new wool warehouse, now scarcely completed, belonging to Messrs. Whitwell & Busher, every obstacle would be remedied. Its loan was at once kindly conceded, and the Show was consequently held there. This warehouse of two storeys is one of the most capacious structures in the northern counties, well and thoroughly lighted from the roof, and possessing fireplaces, and every other needful accommodation for such a meeting. It is most substantially erected, the timbers being of prodigious strength; and the computation of the builder is, that it would sustain in perfect safety on the upper floor a human being to every square foot. In a comparatively very small portion of this compartment the Show took place; and, were it requisite, certainly fifteen hundred pens could be exhibited in single tiers, and every one in a good light. The arrangements were decidedly good, and the only improvement that suggested itself to our minds was, another season (as space allows it), to show every pen side by side, and especially to place the Pigeon pens somewhat nearer the level of the eye by dropping them at the least 2 feet. But to the birds the selves.

Spanish were the first classes on entering, and so good a show we have rarely inspected. The old birds shown were the most numerous; but the silver cup to the best pen in either adults or chickens fell to the latter. For this premium the competition was remarkably close, so much so that the arbitrator remarked, "that to give it to either was an injustice to its opponent, for both were equally good; and, consequently, each was as equally deserving." A considerable time was wasted in the final determination, for it eventually proved both pens were the property of the same breeder, although the Judge was then unconscious of its being so; and the chickens gained the supremacy, simply as from their youth these birds were of the most pecuniary value, and without any disparagement to the older birds. A closer run was never seen; and if Mr. Teebay has others such in reserve, no doubt 1863 will add much to his present high reputation as a Spanish-breeder. The birds shown by Messrs. Fowler, Heath, Robson, and Dixon, were also very good. The Grey *Dorkings* were one of the gems of the Kendal Show, particularly the whole class of old birds. In *Cochins* the Partridge-coloured were the most perfect; and, although the old birds were a capital class, it strangely occurred the chickens were decidedly the least worthy assemblage in the Exhibition. The White *Cochins* were very good indeed; the birds so much

admired at the recent Birmingham Show still maintained their position. Progressing, we come to the heaviest classes of the Show, the *Game* fowls; the display was universally good. To this portion a silver cup was given for the best pen of Any variety; and Red Piles proved the successful ones, the winner being Mr. Harry Adams, of Beverley. We cannot call to mind a single case heretofore in which Piles stood pre-eminent in a general competition; they were a truly wonderful pen, and we believe have been recently shown by another exhibitor. The *Game* chickens, as a whole, greatly lacked condition, attributable in their case, no doubt, to the late damp season. The Golden *Hamburghs*, Pencilled or Spangled, quite outdistanced their lighter-coloured companions. The Golden-spangled were decidedly one of the best collections seen during the past year. In the class for *Single Game Cocks*, the Brown Red shown by Mr. George Whitwell is worthy of our highest praise. This bird secured the plate premium, the whole class being first-rate; but the cockerel class was comparatively indifferent. Among the adults, pen 237 was "disqualified" on account of the breast being painted to hide a deficiency of colour. It is really time some prompt measures were adopted as a reproof for such unfair practices besides "disqualification;" and we shall be glad to hear that committees take the matter in hand where so mean artifices are detected, as they are evidently either very greatly on the increase, or have been more successfully detected of late than formerly. In the cockerel class a remarkably good old bird was shown; but as this might as probably be the result of accident as design—an excuse not available in the "painted" case—we forbear to state the number of this pen, as the loss of a good position in its own proper class, from disqualification in the young birds, entails a sufficient punishment. The *Game Bantams* were very good indeed, the best birds being found in the pens of three. Singularly enough not a Sebright Bantam was exhibited. Some excellent *Silkie*s were shown in this division.

The *Rouen Duck* class was best of any, though the *Aylesburys* were meritorious. Some capital Grey Call Ducks and tamely-reared wild Ducks were entered in the Variety class.

The *Pigeons* were superior, particularly the Carriers, Barbs, Owls, Trumpeters, Turbits, Jacobins, and Powders. In the "Extra class" were many beautiful varieties, and, consequently, the competition was severe. Some Icelanders and splendid Silver Dun Runts were shown. We also noticed a pair of very large White Runts, shown recently at Newport we believe, and would strongly advise their owner to take special care of them, as, if we are correct in recognising them, they are fearfully gone out of condition, sadly damaged in health, and quite spiritless since shown there, even though so recently. It is a pity to lose such birds from neglect.

We were informed by the Hon. Secretaries, Messrs. Whitwell and Wilson, that for future years the obtaining the same accommodation for the poultry then shown had been made a fixed promise, and we congratulate them on so great a boon. It must give increased hopes for future meetings.

SPANISH.—A Silver Cup, the gift of G. Carr Glyn, Esq., M.P., for the best pen. First and Third, R. Teebay, Fulwood. Second, J. K. Fowler, Aylesbury. Highly Commended, A. Heath, Calne, Wilts. Commended, J. Dixon, Bradford; G. Robinson, Kendal. *Chickens*.—Cup and First, R. Teebay. Second, W. H. Hayward, Birmingham. Third, S. Robson, Burton Salmon, Yorkshire. Commended, J. K. Fowler.

DORKINGS (Coloured or White).—A Silver Cup, the gift of Major-Gen. Hon. G. F. Upton, M.P., C.B., for the best pen. Cup and First, J. Robinson, Garstang. Second, J. Dixon, Bradford. Third, R. Sergenceson, Huyt n. Prescot. Highly Commended, J. Moore, Windermere; Major-Gen. Hon. G. F. Upton, Milnthorpe; Miss M. A. Hill, Woodlands, Heywood; T. Burgess, Whitechurch, Salop. Commended, Mrs. M. Seamons, Aylesbury; H. W. B. Berwick, Helmsley, Yorkshire; G. C. Whitwell, Kendal; T. Whittaker, Lancaster. *Chickens*.—First, W. W. Rutledge, Storth End, near Kendal. Second, R. Sergenceson. Third, J. Robinson. Highly Commended, J. Moore; W. W. Rutledge. Commended, D. Steel, Windermere.

COCHIN-CHINA (Cinnamon and Buff, or Brown and Partridge-feathered).—A Silver Cup, the gift of the Managing Committee, for the best pen. Cup and First, J. Shorthose, Newcastle-on-Tyne. Second, R. White, Sheffield. Third, H. and G. Newton, Leeds. Highly Commended, H. Chavasse, King's Heath, Birmingham. Commended, W. Copple, Eccleston. *Chickens*.—First, R. White. Second, T. Stretch, Ormskirk. Third, C. Bower, Bolton-le-Sands, Lancaster.

COCHIN-CHINA (White).—First, G. C. Whitwell, Kendal. Second, J. Dodd, Middlewich, Chester. Commended, G. C. Whitwell. *Chickens*.—First, G. C. Whitwell. Second, R. H. Nicholas, Newport, Monmouthshire.

GAME (White and Piles).—A Silver Cup, the gift of R. L. Watson, Esq., for the best pen. Cup and First, H. Adams, Beverley. Second, F. C. Ellison, Milnthorpe. Third, J. Fletcher, Stoneclough. Highly Commended, G. C. Whitwell, Kendal; W. Wilkinson, Milnthorpe. *Chickens*.—First, J. Fletcher. Second, F. C. Ellison. Third, W. Wilkinson.

GAME (Black-breasted and other Reds).—First and Third, J. Fletcher,

Stoneclough. Second, W. R. Lane, Birmingham. Highly Commended, H. M. Julian, Beverley; Hon. Mrs. Howard, Milnthorpe; D. Parsons, Cuerden, near Preston; T. Robinson, Ulverstone; H. Adams, Beverley. Commended, W. J. Cope, Barnley; R. Parkinson, Poulton-le-Fylde; W. Rogers, Woodbridge; G. C. Whitwell, Kendal. *Chickens*.—First, R. Parkinson. Second, W. Boyes, Beverley. Third, T. Moss, Poulton-le-Fylde. Highly Commended, Hon. Mrs. Howard; A. Sugden, Kendal. Commended, J. Fletcher; T. Burgess, Whitechurch, Salop; Miss J. Taylor, Kendal.

GAME (Any other variety).—First, J. Fletcher, Stoneclough. Second, H. Adams, Beverley. Third, T. Robinson, Ulverstone. *Chickens*.—First, J. Fletcher. Second, J. Hodgson, Bradford. Third, W. J. Cope, Barnley. *HAMBURGERS* (Golden-pencilled).—A Silver Cup, the gift of the Managing Committee, for the best pen. Cup and First, T. Robinson, Ulverstone. Second, J. Robinson, Garstang. Highly Commended, J. Dixon, Bradford; W. Cannan, Bradford.

HAMBURGERS (Golden-spangled).—First, N. Marton, Manchester. Second, J. Dixon, Bradford. Highly Commended, J. Robinson, Garstang; S. Wales, Kendal. Commended, H. W. B. Berwick, Yorkshire; W. Cannan, Bradford; J. Robinson.

HAMBURGERS (Silver-pencilled).—First, J. Robinson, Garstang. Second, W. Cannan, Bradford. Highly Commended, C. Moore, Poulton-le-Fylde; J. Sunderland, jun., Hipperholme, near Halifax. Commended, J. Dixon, Bradford.

HAMBURGERS (Silver-spangled).—First, W. Cannan, Bradford. Second, R. Teebay, Fulwood. Highly Commended, J. Robinson, Garstang.

HAMBURGERS (Any variety).—First, W. Cannan, Bradford. Second, R. H. Nicholas, Newport. Third, H. W. B. Berwick, Yorkshire. Highly Commended, M. Whittam, Settle.

SINGLE COCKS.

SPANISH.—First, R. Teebay, Fulwood. Second, J. Simm, Kendal. Highly Commended, G. Robinson, Kendal.

DORRING.—First, G. C. Whitwell, Kendal. Second, J. Rowlandson, Hawkhead. Highly Commended, W. F. Erithwaite, Eastbourne, Darlington; R. Sergenson, Prescott. Commended, E. R. Whitwell, Darlington; R. Farrer, Bolton; G. C. Whitwell.

COCHIN-CHINA.—First, F. M. Hindle, Haslingden. Second, Rev. F. Wilson, Haslingden. Highly Commended, Rev. F. Wilson. Commended, F. M. Hindle; A. Worthington, Bolton-le-Sands.

GAME.—A Silver Cup, the gift of the Managing Committee. Cup and First, G. C. Whitwell, Kendal. Second, W. Boyes, Beverley. Third, J. Firth, Halifax. Fourth, J. Fletcher, Stoneclough. Highly Commended, J. Fletcher; M. Whittam, Settle; W. Thompson, Moresdale Hall, Kendal; A. Heath, Calne, Wilts; T. Moss, Poulton-le-Fylde; A. Winkill, Kendal; H. Adams, Beverley; G. Lingard, jun., Birmingham. Commended, J. Sunderland, jun., Hipperholme, Halifax. *Cockerels*.—First, R. Parkinson, Poulton-le-Fylde. Second, J. Boulton, Ulverstone. Third, J. Fletcher. Highly Commended, W. J. Cope, Barnley; J. Hodgson, Whittington.

GAME BANTAM.—First, T. Wilson, Kendal. Second, R. Moon, Liverpool. Third, T. Moss, Poulton-le-Fylde. Highly Commended, C. Bower, Lancaster. Commended, W. Laurencson, Poulton-le-Fylde.

BANTAMS (Game).—First, R. Farrer, Bolton. Second, J. Mashiter, Ulverstone. Third, C. W. Brierley, Rochdale. Highly Commended, J. Cragg, Kendal; E. G. Hornby, Westmorland; J. Wilson, Kendal; R. H. Nicholas, Newport; T. Shaw, Kirkham; W. Laurencson, Poulton-le-Fylde; E. Brown, Sheffield. Commended, T. Wilson, Kendal; R. B. Parkinson, Kendal; E. Holdsworth, Leeds.

BANTAMS (Any other variety).—First, Capt. Wetherall, Toddington, near Kettering. Second, R. H. Nicholas, Newport. Commended, G. A. Gelderd, Aikrigg End, Kendal.

DORRINGS (White).—First and Second, J. Robinson, Garstang. Third, E. R. Whitwell, Darlington.

DUCKS (Aylesbury).—A Silver Cup, the gift of John Whitwell, Esq., Mayor of Kendal, for the best pen. First, Rev. F. Wilson, Haslingden, Lancashire. Second, Mrs. M. Seamons, Aylesbury. Third, J. Robinson, Garstang. Highly Commended, Mrs. M. Seamons.

DUCKS (Rouen).—Cup and First, T. Robinson, Ulverstone. Second, J. Sergenson, Kirby Lonsdale. Third, J. Redhead, Kendal. Highly Commended, Mrs. J. A. Alston, Fleetwood; F. M. Hingle, Haslingden.

DUCKS (Any other variety).—First, D. Parsons, Cuerden, Prescott. Second, F. W. Barle, Prescott. Third, R. Sergenson, Huyton, Prescott. Highly Commended, Miss M. A. Hill, Woodlands, Heywood.

PIGEONS.

CARRIERS.—First, W. Cannan, Bradford. Second, S. Robson, Brotherton, Yorkshire. Highly Commended, J. Lewthwaite, Kendal; W. B. Van Haansbergen, Newcastle-on-Tyne. Commended, T. Bateson, Kendal.

ALMOND TUMBLERS.—First, T. Kew, Westmorland. Second, H. Yardley, Birmingham.

TUMBLERS (Any other breed).—First, H. B. Pring, Newport, Monmouthshire. Second, F. Else, Bayswater, London. Highly Commended, J. Monkhouse, Kendal; W. Cannan.

OWLS.—First, W. Cannan. Second, J. & W. Towerson, Egremont, Cumberland.

POWTERS OR CROPPERS.—First, E. Brown, Sheffield. Second, S. Robson, Brotherton. Highly Commended, T. Kew. Commended, W. Cannan; H. Yardley, Birmingham.

BARBS.—First, A. L. Silvester, Birmingham. Second, M. Irvine, Whitehaven.

FANTAILS.—First, J. W. Edge, Birmingham. Second, F. Brown, Sheffield. Commended, F. Else, Bayswater, London; F. Key, Beverley; J. R. Jessop, Hull.

TURBOTS.—First, R. Thompson, Kendal. Second, J. Barrow, jun., Kendal. Highly Commended, F. Else, Bayswater, London; A. L. Silvester, Birmingham; J. W. Edge, Birmingham.

TRUMPETERS.—First, J. Wilson, Darlington. Second, F. Key, Beverley. Highly Commended, F. Key; W. B. Van Haansbergen; H. Yardley, Birmingham; S. Robson, Brotherton. Commended, T. Kew, Westmorland.

JACOBS.—First, A. L. Silvester, Birmingham. Second, H. Yardley, Birmingham. Highly Commended, R. Thompson. Commended, F. Else, Bayswater, London.

ANY OTHER VARIETY.—First, A. L. Silvester, Birmingham. Second, M. Irvine, Whitehaven (Runts). Highly Commended, J. W. Wooler

(Spangled Swabians); H. B. Pring, Newport (Runts, Spanish imported); R. Thompson, Kendal (Nuns). Commended, A. Heath, Calne, Wiltshire (Isabels).

Mr. Edward Hewitt, of Sparkbrook, near Birmingham, officiated as the Judge.

GAME FOWLS.

"E. A. S." seems to wish that the Game classes should be judged by plumage only, and not for their game qualities. If so, instead of being, as they now are, one of the gems of the exhibition, their character would be totally changed, and a great portion of the interest now taken in them would cease. As "E. A. S." seems to take such interest in them, perhaps he will tell us the whole of the qualities necessary for perfection in a pen of Black Red Game.—AN EXHIBITOR.

DISQUALIFIED BLACK BANTAMS AT DARLINGTON.

I HAVE just returned home, having been absent since the middle of November, and during that time I have not seen a copy of your Journal. I now find that the Black Bantams lately exhibited by me at Birmingham and Darlington have been the subject of some discussion, and I take the earliest opportunity of explaining the matter.

Your correspondent "JUSTITIA" is quite correct in saying I claimed the pen (for £3) at the Crystal Palace Summer Show. They were exhibited by Mr. Hutton, and were "highly commended." He (Mr. Hutton), as he says, took first prize with another pen on which he had £2. I preferred the highly-commended pen at £3 to the first-prize pen at £2, and claimed them. As soon as the birds arrived at home I sent them out to a walk, and did not see them again till a few days before I left home in the middle of November, when my man brought them up, and I discovered that the cock's legs had changed to white. As I was leaving home immediately, my man was anxious to know what was to be done. I told him to write off to Mr. Hutton at once, and inquire if he had any good cocks to dispose of. He wrote back saying that he had, and asked £2 each for them. My man requested him to send two on approval. They arrived (I being from home), and my man assures me that they were perfectly valueless for exhibition, one having legs as bad as the bird I already possessed and being worse in other points, and the other having red earlobes. He (my man) was quite at a loss what to do. He did not know where to apply to for another bird, and he had not time to write to, and receive an answer from, me before sending to the Birmingham Show; so he concluded the only plan was, as he thought, to follow the example of the former owner of the birds and colour the cock's legs. He did so, and they were sent to Birmingham and Darlington in that condition. I suppose his success at the former Exhibition encouraged him to send again to the latter. When they were sent to Birmingham I was in the south of England, and when to Darlington in Scotland, and knew nothing at all of the affair. If I had been at home, they certainly would not have been sent.

In your Journal of December 16th you say "This pen at the recent Birmingham Meeting took first prize among a heavy class." You would have been much nearer the truth if you had said "among a weak class," as by reference to the Birmingham catalogue you will find that only four pens were exhibited. When I claimed the pen at the Crystal Palace the cock's legs were, to all appearance, perfect. Mr. Hutton says "that not the least particle of colouring matter, or stain of any other kind whatever, was laid on, or came in contact with, the legs of the birds referred to, by either myself or any other person, previous to their being dispatched to the Show." I suppose we are in courtesy bound to believe him; but it certainly is the most peculiar case that ever came under my notice, that a bird's legs should change from black to white in three short months. When my man wrote to Mr. Hutton he explained why I wanted another cock; but, in his reply, that gentleman offered no explanation, or even mentioned the bird's legs, confining himself to the mere fact that he had birds to dispose of.—THE EXHIBITOR OF THE DISQUALIFIED PEN OF BLACK BANTAMS AT DARLINGTON.

[We consider the above explanation exculpates Mr. Munn, and his sincerity is sustained by the fact that he has returned to

the Exhibition Committee the prize awarded to the Bantams at Birmingham. The culprit now would appear to be Mr. Hutton, for it is quite certain that the natural colour of the legs of the Bantam would not change.—EDS. J. OF H.]

SCOTTISH ORNITHOLOGICAL ASSOCIATION.

THE fourth annual Exhibition and competition of fancy Pigeons and Canary birds, under the auspices of this Association, took place on the 1st and 2nd inst. in the Trades' Hall, Glassford Street.

In the *Pigeon* department the Show was excellent; and although the entries were not so numerous as at last year's exhibition, still the birds shown were superior, if not unequalled.

In the *Power* and *Carrier* classes the birds were exceedingly good, as were, indeed, all kinds of Pigeons exhibited.

The entries in the *Canary* department were not so large as last year, but this is to be accounted for in a great measure by the number of local exhibitions taking place on the same day; but in consequence of the prizes at this Exhibition being the most valuable, the show of birds was superior. A circumstance almost unprecedented we believe, occurred at this Show—viz., the pair of Canaries which took the first prize last year were again successful on this occasion. There was a fine display of Canaries, and some of the finest Mules we have seen were shown. The following are the awards:—

PIGEON DEPARTMENT.

EXTRA PRIZES.

A Silver Cup, presented by the Association, for the best three pens (Carriers, Powters, and Short-faced Almond Tumblers), G. Ure, Dundee. Very Highly Commended, P. Eden, Manchester.

A Silver Medal, presented by W. Smith, Esq., Halifax, for Powter cocks (Black, Blue, and Yellow), P. Eden, Manchester.

A Silver Medal, presented by P. Eden, Esq., for Powter hens (Black, Blue, and Yellow), J. Huie, Glasgow.

A Silver Medal, presented by J. Miller, Esq., Camlachie, for Blue Powters bred in 1862, G. Ure, Dundee. Very Highly Commended, A. Muir, Coatbridge.

A Silver Medal, presented by J. Huie, Esq., Glasgow, for Yellow Powters bred in 1862, M. Stuart, Glasgow.

A Subscription Silver Medal for Powters, any colour (Blue and Yellow excepted), bred in 1862, P. Eden, Manchester (White). Very Highly Commended, G. Ure, Dundee (White). Highly Commended, J. Millar, Glasgow.

POWTERS (Black cocks).—First, H. Hawkins, Belfast. Second, M. Stuart, Glasgow. Very Highly Commended, M. Stuart. Highly Commended, J. Millar, Glasgow. Commended, J. Huie, Glasgow.

POWTERS (White cocks).—First, P. Eden, Manchester. Second, G. Ure, Dundee.

POWTERS (Blue cocks).—First, M. Sanderson, Edinburgh. Second, H. Hawkins, Belfast. Very Highly Commended, J. Millar, Glasgow. Highly Commended, M. Sanderson.

POWTERS (Red cocks).—First, H. Hawkins, Belfast. Second, G. Ure, Dundee. Very Highly Commended, H. Brown, Sheffield.

POWTERS (Yellow cocks).—First, G. Ure, Dundee. Second, P. Eden, Manchester.

POWTERS (Any other colour).—First, J. Huie (Mealy). Second, W. Taylor, Sheffield. Very Highly Commended, W. Lightbody.

POWTERS (Black hens).—First, J. H. Frame, Carlisle. Second, P. Eden, Manchester. Commended, G. Ure, Dundee. Highly Commended, J. Millar, Glasgow. Very Highly Commended, J. Huie, Glasgow.

POWTERS (White hens).—First, H. Hawkins, Belfast. Second, G. Ure, Dundee. Highly Commended, J. Huie, Glasgow.

POWTERS (Blue hens).—First, G. Ure, Dundee. Second, J. Ruthven, Glasgow. Very Highly Commended, J. Huie, Glasgow.

POWTERS (Red hens).—First and Second, G. Ure, Dundee.

POWTERS (Yellow hens).—First, G. Ure, Dundee. Second, J. Huie, Glasgow.

POWTERS (Any other colour).—First, J. Muir, Glasgow (Chequer). Second, M. Stuart, Glasgow (Mealy).

A Silver Medal, presented by J. Wallace, Esq., for Carriers (any colour) bred in 1862, J. Huie, Glasgow (Black). Very Highly Commended, J. Wallace, Glasgow. Highly Commended, J. Huie, Glasgow.

CARRIERS (Black cocks).—First, H. Martin, Glasgow. Second, G. Ure, Dundee. Very Highly Commended, J. H. Frame, Carlisle.

CARRIERS (Dun cocks).—First, T. Colley, Sheffield. Second, J. Wallace, Glasgow.

CARRIERS (Black hens).—First, J. R. Rennards, Helensburgh. Second, P. Eden, Manchester. Very Highly Commended, W. B. Van Haansbergen, Newcastle.

CARRIERS (Dun hens).—First, T. Colley, Sheffield. Second, J. R. Rennards, Helensburgh. Very Highly Commended, T. Colley.

A Silver Medal, presented by G. Ure, Esq., Dundee, for Almond Tumblers bred in 1862, P. Eden, Manchester.

SHORT-FACED TUMBLERS (Almonds).—First and Second, M. Stuart, Glasgow.

SHORT-FACED TUMBLERS (Mottles, any colour).—First, P. Eden, Manchester (Mottles). Second, G. Ure, Dundee (Black Mottles). Very Highly Commended, W. H. C. Oates, Newark (Red Mottles).

SHORT-FACED TUMBLERS (Any other colour or variety).—First, R. Fulton, London. Second, M. Stuart, Glasgow (Red Agates). Cock Very Highly Commended, H. Martin, Glasgow. Highly Commended, R. Pickering, Carlisle (Red). Commended, M. Stuart, Glasgow (Kites).

A Silver Medal, presented by E. Gilroy, Esq., Lanark, for Barbs (any colour) bred in 1862, P. Eden, Manchester (Black).

BARBS (Cocks).—First, J. H. Frame, Carlisle (Black). Second, P. Eden, Manchester. Very Highly Commended, J. H. Frame (Red).

BARBS (Hens).—First, P. Eden, Manchester. Second, J. Green, Overton (Black).

A Silver Medal, presented by Lord Binning, for Fantails (any colour) bred in 1862, J. Wallace, Glasgow. Very Highly Commended, J. H. Frame, Carlisle (White). Highly Commended, D. Stewart, Perth (White). Commended, F. Else, Dundee.

FANTAILS.—First, J. Huie, Glasgow. Second, G. Ure, Dundee. Very Highly Commended, G. Ure (White). Highly Commended, F. C. Parker, Dundee.

JACOBS.—First, A. L. Silvester, Birmingham. Second, J. Ruthven, Glasgow (Yellow). Very Highly Commended, N. Morton, Ballymena, Ireland (Red). Highly Commended, J. R. Rennards, Helensburgh.

TRUMPETERS.—First, J. Bell, Newcastle. Second, H. Yardley, Birmingham. Very Highly Commended and Highly Commended, G. Ure, Dundee (Black Mottled). Commended, N. Morton, Ballymena, Ireland (Mottled).

TURBITS.—First, A. L. Silvester, Birmingham. Second, F. Else, London. Very Highly Commended, J. W. Edge, Birmingham. Highly Commended, J. R. Rennards, Helensburgh.

OWLS.—First, F. Else, London. Second, J. R. Rennards, Helensburgh. NUNS.—First, J. R. Rennards, Helensburgh. Second, F. Else, London. Very Highly Commended, J. W. Edge, Birmingham.

MAGPIES.—First, W. M. Gilmour, Hamilton. Second, N. Morton, Ballymena, Ireland.

COMMON TUMBLERS.—First, J. Sephton, Prescot. Second, J. W. Edge, Birmingham. Very Highly Commended, J. Sephton. Highly Commended, A. Morrison, Glasgow (Red Mottles).

OTHER BREEDS.—First, F. C. Parker, Dundee (Lace Fantails). Second, A. L. Silvester, Birmingham. Third, W. H. C. Oates, Newark (Isabels). Very Highly Commended, H. Yardley, Birmingham (Swallows). Highly Commended, W. M. Gilmour, Hamilton (Blue Priests).

CANARY BIRD DEPARTMENT.

EXTRA PRIZES.

A handsome piece of Silver Plate, and £1 1s. as a second prize, presented by the Association, for Scotch fancy, the produce of 1861, or prior thereto (Yellow Cock and Buff Hen, or Buff Cock and Yellow Hen). First, G. Buchanan, Glasgow. Second, W. Hunter, Kilbirnie.

SCOTCH FANCY.—A special prize, presented by G. Buchanan, Esq., for Yellow or Buff Cock. *Yellow Cocks*.—First and special, G. Buchanan, Glasgow. Second, W. McLeod, Glasgow. Third, J. Fulton, Beith. Fourth, T. McMurtrie, Kilmarnock. *Buff Cocks*.—First and special, D. Stewart, Perth. Second, A. Ferguson, Kilmarnock. Third and Fourth, D. Gunn, Glasgow.

A special prize, presented by the "Thistle Ornithological Society," Glasgow, for Yellow or Buff Hen. *Yellow Hens*.—First and special, G. Masterton, Glasgow. Second, D. Duncan, Carron. Third, G. Buchanan, Glasgow. Fourth, D. Gunn, Glasgow. *Buff Hens*.—First, G. Masterton, Glasgow. Second, S. Brown, Glasgow. Third, G. Buchanan. Fourth, J. Johnston, Kilmarnock.

BELGIAN FANCY.—A special prize, presented by Messrs. Paterson and Buchanan, for Yellow or Buff Cock. *Yellow Cocks*.—First, J. Goddard, Kendal. Second, D. Talbert, Dundee. Third, J. Ruthven, Glasgow. *Buff Cocks*.—First and special, J. Huie, Glasgow. Second, J. Toward, Glasgow. Third, Mrs. Clark, Glasgow. *Yellow Hens*.—First and special, J. Harding, Dumfries. Second, Mrs. Clark. Third, J. Simpson, Edinburgh.

A special prize, presented by M. Stuart, Esq., for Yellow or Buff Hen. *Buff Hens*.—First, J. Ruthven, Glasgow. Second, J. Simpson, Edinburgh. Third, Mrs. Clark, Glasgow.

PIEBALDS.—A special prize, presented by the Association, for Yellow or Buff Cock or Hen. *Yellow Cocks*.—First, W. M. Murray, Edinburgh. Second, R. Borland, Glasgow. Third, N. M. Leod, Glasgow. *Buff Cocks*.—First and special, N. M. Leod, Glasgow. Second, W. Clason, Glasgow. Third, J. M. Kimmin, Govan. *Yellow Hens*.—First, A. Riddell, Carron. Second, M. Henderson, Ardrossan. Third, J. Fulton, Beith. *Buff Hens*.—First, J. Armstrong, Glasgow. Second, N. M. Leod. Third, R. Lawrie, Glasgow.

GOLDFINCH MULES.—*Yellow Cocks*.—First, W. Wilson, Manchine. Second, G. J. Barnaby, Derby. *Buff Cocks*.—First, W. Bainbridge, Ayr. Second, R. Foster, Carlisle.

The following were the Judges:—Of Pigeons:—E. L. Corker, Esq., Croydon, Surrey; and D. Wolstenholme, Esq., Gray's-Inn Road, London. Canaries:—Messrs. W. White, Renfrew; J. K. Johnstone; J. Graham, Kilmarnock; G. Ayton, N. M'Lean, and D. Johnstone, Glasgow.—(*Glasgow Herald*.)

LEGS OF GAME BANTAMS.

FOR the information of your correspondent in last week's paper on the subject of "Yellow-legged Game Bantams," I write to say that for the last two years I have had a Yellow-legged cock of that breed, a bird that I am very proud of. At the commencement of last breeding season I shut him up with a Blue or Slate-legged hen, trusting that the mixture of blue and yellow would make green as the paint does, but I was disappointed—my birds were principally Slate-legged, a few White-legged, and one cockerel Yellow-legged like his father. I showed him at Birmingham, he was highly commended and sold at the price I put upon him—viz., £3. A cockerel and two pullets, Slate-legs of the same hatch took a prize at the Sparkenhoe Show at Leicester last September, which clearly proves that the prizes are not solely for Willow-legged birds. Last year I had also a Yellow-legged Black-breasted Red Game cock, which I mated with some Blue and Willow-legged hens. The result invariably

was Blue-legged chickens from Blue-legged hens, and Willow from Willow-legged mothers, with a very few exceptions where the yellow peeped out, in which cases I destroyed the chickens, well knowing the prejudice against the yellow legs in Game fowl, though I do not believe that hitherto it has extended to the Game Bantam class.

Would it not be much better if there were some fixed standard to go by? so as to make it impossible that an exhibitor should say, "Oh, Mr. So-and-So is Judge. Well, it is no use sending my fowls, he won't give a prize to any but Willow-legged ones." What a drawback to a show! Why should not each show publish in the catalogue of prizes the particular points of the fowls in each class requisite to enable them to take a prize? It would save a world of trouble, and a great deal of disappointment and dispute.—W. P.

CORK POULTRY SHOW.

THE third annual Exhibition of the South of Ireland Poultry Association was held on the 7th and 8th of January, in the large rooms of the Athenæum at Cork. The rapid and steady progress made by this Society must be most gratifying to its promoters; for it has now attained a position that would reflect credit on any town in the United Kingdom.

The following is the prize list:—

SPANISH.—First, Miss De Courcy Drevar. Second, F. Hodder. *Chickens*.—First, F. Hodder. Second, Mrs. Dring.
DORKINGS (Coloured).—First, Mrs. Webb. Second, Mrs. Dring.
DORKINGS (Silver-Grey).—First, A. E. Usher. Second, T. O'Mahony. *Chickens*.—First and Second, A. E. Usher.
DORKINGS (White).—Prize, T. O'Mahony.

WILD DUCKS REARED WITH TAME.

I WILLINGLY concede to the request of your correspondent "J. R." for further information respecting my former pets, the wild Ducks. Permit me to add, we invariably pinioned all the offspring as well as the primitive generation produced from the eggs of birds still in a state of nature, as they all proved themselves not to be certainly depended upon in case of any sudden alarm or stress of weather, of which they were peculiarly susceptible. The approach, for instance, of any strange dog or cat caused them to rush headlong into the water, dive about, and make their best repeated efforts to take wing until they became really exhausted. To show their power of discrimination on the other hand, our own dogs and cat were always running about quite unregarded, and all three of them frequently lay down and stretched themselves listlessly about in the sunshine, in the closest proximity to the Ducks—"a happy family." So much did this difference to them and strangers manifest itself, that I have seen the Ducks walk softly to the dogs and snap at their hair when they wished to drive them away from a spot they themselves coveted. Any positive change of apparel in my sister to that she customarily wore when among them, caused them at once to move away, as they always did from an absolute stranger. It was evident they depended at once entirely on the eye when thus withdrawing to a distance, for a kind word or two from my sister instantly recalled them, though for a few minutes or so they might still regard her very suspiciously. Usually they fed without hesitation from the hand. I never tried to breed between the true Mallard and the tame Duck. In justice to their constancy, I never knew any tendency of disposition on their parts to bigamy, or wanderings after other female specimens of waterfowls that might be with them of a different variety. On the contrary, I have seen a Mallard fight desperately with a strange odd male of his own species on his venturing too near the mate of his particular selection. They always paired for the years we kept them, as we never to the best of my recollection bred them beyond five or six generations, as they then proved so much less beautiful. The white collar round the neck of the Mallard then became much broader and far more irregular; and another great token of domestication carried beyond due limit was, the appearance of white in the few longest flight-feathers of the ducklings' wings. In all such cases we immediately resorted to wild-laid eggs again, and put away those previously reared altogether.

Having given my experience of the Mallards of the true wild Ducks, however ungallant it may appear, I must say a word or two on the Ducks only. They seemed inclined to stray from

allegiance to their mated partners. One wild Duck particularly, after breeding a couple of seasons with her own Mallard, at once shook him off on my placing a drake Pintail on the water. It was evidently a case of love at first sight, for she swam about the new comer caressingly, though he appeared evidently alarmed and averse to her overtures of affections. From that hour she fought her old partner. Winter passed by, and the next spring the Pintail seemed to have become a convert to her blandishments, for they nested and produced seven or eight young ones. Six were ultimately reared, and, strangely, proved all drakes. They were most curiously-marked "hybrids," having much of the outline of the father—viz., the Pintail's bill, length of body, dark legs, &c.; but when moulted they all assumed the chestnut crop of a true Mallard, and still more singularly, a triple row of curled feathers in the tail; the proper tail-feathers being also much longer than a wild Mallard's. They were considerably larger than either of their parents, but proved altogether hybrids, never associating with their companions. At length, although exceedingly beautiful, we parted with them.—EDWD. HEWITT, *Spartbrook, Birmingham.*

ASCERTAINING THE SEX OF GOSLINGS.

At the late Birmingham Show I claimed from Mr. Manfield the first-prize pen of young white Geese. I exhibited them for the first time at Manchester, when they were disqualified, two if not all of them being ganders. Mr. Manfield also exhibited a pen there, and it is rather a singular fact that they were disqualified for the same reason.—J. MUNN.

[We know of no mode of ascertaining the sex of live young Geese: therefore there is no delinquency in the above cases; but we think Mr. Manfield ought to let Mr. Munn have Geese in exchange for the superfluous ganders.—EDS.]

HYBRID BETWEEN THE COMMON PHEASANT AND THE SILVER PHEASANT.

HAVING noticed a query on this subject in your last Number, I write to inform you that a gentleman in this town has a stuffed specimen of this hybrid, a male bird. It was shot some years ago near Raby Castle, the seat of the Duke of Cleveland, where some Silver Pheasants had been a short time before turned loose. The plumage is certainly very beautiful, and (if it is possible to judge from a stuffed bird), the size and shape are good.—C. P., *Darlington.*

You are mistaken in saying that there has never been a cross between the common and Silver Pheasant. There are several places here, in Yorkshire, where they breed in the preserves every year. The cross is generally a Pied variety; but it is not desired or highly prized by gamekeepers; they consider the birds weak and tender, and not easily reared. In the "Zoological Proceedings" of 1836, is mentioned a cross between the common Pheasant and the Silver Pheasant, and between the common Pheasant and the Golden Pheasant.—S.

THE WARBLERS.

I COME now to the migratory insect-feeding warblers, many of which are our finest songsters. They arrive in spring, about the 10th of April, when the first broods of caterpillars are being hatched by the return of warm weather, and on them and the larvæ of other insects they raise their own broods; and, as summer advances, insects of various kinds are added to their bill of fare. They arrive in this country when insect life is first awakening from the sleep of winter, stay with us while these pests are active, and depart in autumn when the colder nights warn them their food will soon be less easy to procure. Thus by an allwise decree they are sent to assist in checking that rapid increase of insect life; silently and almost unnoticed they spread over the whole country doing their mission of good, to assist in the protection of every crop. Yet I have said birds are not an unmixed good, and truth compels me to say that many, perhaps nearly all, of these migratory insect-feeding birds do take tithe

of the fruit which they have assisted in saving from utter destruction by insects.

In enumerating the warblers, the Nightingale—the most delightful of all songsters—must head the list; second in the choir comes the Blackcap, then the Garden Warbler, followed by the Wood Wren, Willow Wren, Chiffchaff, Whitethroat, Lesser Whitethroat, Wheatear, Redstart, Furze Chat, Grass-hopper Warbler, Reed Warbler, and Sedge Warbler. Each of these birds has its favourite haunts and insect-food. Thus it will be seen that they all contribute to the destruction of insect pests; nevertheless, it must not be forgotten that those that are most active in the gardens and orchards, eating and keeping in check the insects that would destroy the buds, blossom, leaves, and fruit of the bushes and trees—as, for instance, the Blackcap, Whitethroat, Garden Warbler, and Willow Wrens—are just those that take most tithe of fruit for their pains.

Gardeners, generally, are not well acquainted with the habits of birds, nor do they often know all the species that visit their gardens and plantations; most of these are plain-coloured birds, and by the unobservant may be passed by as Sparrows, or certainly under that all-including title—*small birds*. The object of these papers is to awaken in gardeners a spirit of observation, that they may learn how best to save their fruit. I do not deny that small birds eat fruit. I am well aware that many are very annoying in their attacks on various crops; but then, if we are to kill-off every bird that is in the least injurious, how shall we save our crops from utter destruction from the increase of insects? That birds do an immense amount of good is an established fact, and without them few crops can be depended on; that which I have always advocated is to save the birds as our best friends and allies against the armies of insects that would otherwise devastate our crops. At the same time, I would endeavour, as far as possible, to protect the sown seeds and rising crops, as well as the ripening seeds and fruit, from their taking too heavy a tithe, or too high wages for their labour. The case will stand thus: The closer you kill-down the birds the more troublesome will be the insects, and consequently the smaller and smaller becomes the crop. But where the birds are in full force so as to enable them, each sort, to keep in check their favourite insect-food, then (weather permitting, for the birds cannot alter the season) will the trees be enabled to produce fruit, though the birds may claim a share if they are not kept off at the proper time. Or, it amounts to this: Will you kill-off the birds and preserve the insects that you may have no fruit to be bothered about? or will you save the birds to destroy the insects, and so, taking the chance of the season, have a good crop and some trouble to protect it? The question is, Is a large crop worth that trouble?—B. P. BRENT.

BEE SEASONS IN SURREY.

HAVING taken great interest in, and derived much instruction from, the communications on bee-keeping furnished by various of your contributors, I feel pleasure in sending you an account of my experience in bee-keeping during the seasons of 1861-2, in this part of the country (southern part of West Surrey). Both seasons have been bad, particularly the latter year.

I keep my hives in houses, made to hold six in two tiers. I began the season of 1861 with six stocks, of which two gave out three swarms each, three others gave one swarm each, and one stock did not swarm—nine swarms altogether.

Wishing to increase the number of my stocks, I hived them all separately. The first swarm came off on the 4th June; the next swarm from another hive came out June 13th. Up to this time not a drone was seen to come from any of my hives. The next day I saw two or three drones come from the hive that swarmed June 4th, ten days after the swarm; and again drones did not issue from the hive that swarmed June 13th until ten days after the swarm. I think that very late for drones to make their appearance. Both these hives gave three swarms each; after which I placed a small glass on one of them, and took about 3 lbs. of honey. From the two first swarms of these stocks I also took small glass supers of honey. Of the two second swarms or casts one did very well, the other not so well and it died last winter, but not for want of food. Of the two third swarms (or colts, or smart, as some people call them), which are said by some not to be worth keeping by themselves, both did very well, one of them becoming in the autumn the strongest of all my hives. Indeed, the bees were clustered outside so

strong on the 1st of October that I determined to put on a small glass super, with a little empty comb in it, to see if they would deposit any honey, which they were then collecting in great quantities from the ivy. I took a small quantity from the super on the 7th October; but it tasted so strong of the ivy that a very small bit nearly made me sick, and I did not dare to touch it again. Have any of your correspondents noticed a similar nauseous taste in honey taken so late?

The doings of this third swarm the next season (1862) will be particularly noticed hereafter, because it shows that in some localities second and third swarms, although small, as the one referred to was, can be hived by themselves and expected to do well that and the following season, notwithstanding the statements to the contrary contained in most books on bees. Of the other stocks and swarms I have nothing particular to note. The autumn of 1861 found me with fifteen hives—the six stocks I commenced that season with, and the nine swarms. I improperly deprived two of the stocks of most of their stores in August. They were not able to replace their store, did not prosper after, and died the following winter—a caution to me for the future. These two deaths, together with that of the second swarm previously referred to, left me with twelve stocks to commence the season of 1862. The results of the year 1862 shall be given in another communication.—A SURREY BEE-KEEPER.

IN-DOOR APIARIES, AND RUNAWAY SWARMS.

IN reply to the queries of "A NORTH-STAFFORDSHIRE BEE-KEEPER" in No. 92, of the 30th of December, 1862, I have the pleasure of sending the following remarks:—

From what experience I have had of keeping bees within doors, I have no hesitation in recommending this mode to any apiarian not possessing a regular bee-house. Its formation may thereby be saved (and they are in too many instances anything but ornamental structures), should he have a spare room or closet in his dwelling or office-houses; or a staircase window may be turned to good account for a like purpose, always providing that the situation be dry, quiet, cool, and airy, and the hive brought to within an inch or two at farthest of the external atmosphere, otherwise dysentery would in all probability set in. Even the village cottager, who has but his garret, may there place his bees beyond the reach of depredators, independent alike of either milk-pans or straw-hackle; if unlatched so much the better, as then there is no obstacle to his fitting at once his box-front to the bevel of the roof, an entrance-slit being cut in the boards, to which the slates are attached to tally with a corresponding one in the box, over which a slate can be raised by a couple of wedges three-quarters of an inch thick at outer end. This admits of space enough for the bees crowding in at the approach of a shower. Should the box be placed half-way up the roof, and top and bottom furnished with bar and slides, or like convenience, he may super, nadir, or work collaterally to his heart's content, only taking care that the skylight be so far moveable as to admit of the exit of any bees escaping during such operations, as they fly to the light. The cottager may thus very simply establish an apiary; and I have seen that apartment converted into an extensive aviary for breeding canaries or other birds; and should the two be combined he could in his leisure hours survey the operation of his bees through the window of his hives, solaced by their pleasant busy hum and the merry song of his birds.

I have found bees thrive as well, if not better, 20 to 30 feet, or even 40 feet, from the ground with a north aspect, than in my Gordon-hives at as many inches when due S. or S.E. However, our situation is not an exposed one; and, in addition, the force of the northerly blast is broken by old trees beyond the garden wall. At such an altitude the bee-keeper is of course necessitated to work exclusively on the depriving or other plan to prevent swarming. Were they to issue they would generally be lost, either from flying a long distance before settling, or alighting on a tree-top.

"A NORTH-STAFFORDSHIRE BEE-KEEPER" wishes to learn the history of an observatory-hive to which I some time ago made allusion, to detail which in a measure involves a description of its predecessor from whence it sprung, and which will equally serve his purpose. In close proximity to a little press containing the boxes of a vagabond stock, located for many years in our

roof (a description of the working of this and other roof-hives your correspondent will find in *THE COTTAGE GARDENER*, No. 589, 10th of January, 1860), was a little half staircase window facing the north, there serving the purpose of a press, and into which I resolved to place a stock. In order to bring the inmates nearer the outside, I removed some 3 inches of mastic plaster, then a pair of thick shutters, the fruits of the window-tax blockade, and cutting an entrance through the centre of the bottom of the frame placed on a shelf flush with the sill. On the 7th of June, 1859, I had a small first swarm (2 lbs. 14 ozs.), in a Stewarton-box, and on the 30th of the same month I hived another a large swarm (5 lbs. 11 ozs.) in another Stewarton, and placed it underneath the preceding. The united colony wrought well—quite equal to any of my other strong stocks, the beginning of September finding them with three boxes full, the nett contents of which weighed 43 lbs. 13 ozs., having previously yielded a handsome two-guinea super. I removed the lower box-comb so soon as the inmates had ascended for the winter, and instead introduced an eke: this box was returned the following season as soon as they required room. Beginning of March, 1860, I again weighed the hive, and found the nett contents 33 lbs., or a deficiency of 10 lbs. 13 ozs. against the six months' keep of this strong colony. That season was inferior to its predecessor, but, doubtless, partly owing to its immense population, the hive yielded a super rather heavier than in the preceding seasons, and now, having fairly outgrown my space in height, I resolved to appropriate its contents; but, fearing a large part of the population would return to the window and be troublesome, although united to another stock at a different stance, I put a young queen and a small body of workers in the empty observatory in its stead, and, after a hunt through the remaining five compartments of the Stewarton, at last secured and destroyed the old monarch, and united her subjects with those of the observatory. The nett contents of the three upper boxes containing the honey weighed, after the bees were removed, 49 lbs. 7 ozs.

I fed the large population of the observatory liberally with the inferior part of the contents of their old hive, and an abundant supply of sugar syrup. Comb-building went on briskly in the full light, and as the season advanced I had a good opportunity of observing the effect of the lowering temperature on the inmates till it reached the extreme point of 25° of frost on the memorable morning of the 24th December. Contrary to my expectation they came through in fine order, and were kept regularly supplied with food till the spring was far advanced, when a long tack of northerly wind caused me to cease feeding during its continuance, fearing to disturb them unnecessarily, and trusting to their surplus store. In this I quite miscalculated, for to my no small chagrin I one day found all still, the bees packed-up between the combs, and after sweeping them off the comb saw that not a cell contained food. Had I then the experience I accidentally became possessed of last spring, that the majority of the population of a hive when in that benumbed, starved, and seemingly dead condition for a short time, may be resuscitated by being brought in contact with a gradually increasing temperature, this observatory-hive might still be in full operation.

Your Staffordshire correspondent's remaining query as to how vagrant swarms prefer a high situation, such as a roof church-tower, &c., can only be accounted for by their known instinct in dispatching scouts so soon as swarming becomes imminent, to select some suitable situation to which the young colony may migrate, and that the above or some hollow tree is the only place with a sufficiently contracted entrance to exclude marauders to which they can gain undisturbed admission, besides, as your correspondent suggested, possessing an equable temperature, to which may be added the suitable considerable bevel of the roof, removing all dampness and débris. It is singular the predilection bees have for such a situation; more particularly when once a swarm has established itself, others are sure to follow. I have often watched with interest the daily increasing surveying-roof party of scouts, the invariable precursors of a swarm. If they suddenly cease their visits it may be concluded they have come off and been captured; but should the space contain in addition the empty comb of a defunct colony, they will even abandon their new hive after working therein. That bees in such situation thrive and prosper is undoubted; aided doubtless by generally selecting a north aspect, their dormancy is more complete, and the drain on their store at a minimum, so that they rarely perish from starvation. I have myself measured stretches of comb in one roof extending to 6 feet in length; in another a few miles distant

the proprietor, on plundering several of the roof-hives, required to employ washing-tubs to contain the mass of combs of various hues. The roof of the Lord of the Manor, as recorded in No. 9, possesses quite a talismanic influence, and is a standing terror to all the surrounding cottage bee-keepers. I related in that Number the chase of one after a swarm. It is, however, fair that I should mention it has since come to my knowledge, that although the details of that story were as related, still my informant was not aware that the stock from which the swarm proceeded was placed at a farm standing nearer the manor-house a good deal than his own dwelling.

The last laird had a great liking to the bees, but failed to induce them to work-out into boxes fitted-up for their reception—very likely from not having sufficiently contracted the space where they were located—but consoled himself by having always the lath and plaster removed from the divisions where the bees established themselves, boards kept in their place with small buttons being substituted; so that, with the aid of a little smoke, the butler could promptly procure, when ordered, a piece of beautiful honeycomb fresh from the hive to sweeten the repast of his friends. His successor being no apiarian, and fearing the bees might penetrate to the very nursery, had them removed and the seams papered-up with stout paper; but notwithstanding, the following season brought as usual a large prime swarm, which, nothing daunted, occupied the favoured site, having cut a suitable entrance through the paper. They survived last winter, and were very strong in spring, when they were mercilessly banished—not, however, without inflicting signal vengeance on their destroyers. The whole slates were removed from the north end, which was covered with roofing felt before they were replaced; and it now remains to be seen if this prove a sufficient preventive against the inroads of our indefatigable little favourites.

—A RENFREWSHIRE BEE-KEEPER.

BOTTLE-FEEDERS FOR BEES.

One Who Has Bees would like to know what kind of bottle is used for feeding, and how it is applied to straw skeps having a four-inch opening on the top, with the combs built across it.

[Any kind of bottle will answer the purpose, but those with short necks and of a squat shape are the most convenient. For occasional feeding in spring, nothing answers better than a common four-ounce or six-ounce medicine-phial; whilst for copious feeding in autumn, an ordinary pickle-bottle leaves nothing to be desired. The best arrangement for straw skeps with a four-inch opening, is that recommended by "A DEVONSHIRE BEE-KEEPER" for wooden hives, and delineated in Vol. XXV., page 42. The opening in the top of the hive is covered with a piece of perforated zinc, on which is placed a block of wood 5 inches in diameter, with a central hole to receive the bottle-neck. The bottle filled with liquid food, and having its mouth covered with a piece of coarse cap-net, the meshes of which are not less than a sixteenth of an inch in diameter, should be quickly inverted over the opening in the wooden block, so that any food that escapes may run into the hive, and its neck being inserted therein, it will stand steadily in an inverted position, whilst the food remains perfectly suspended by atmospheric pressure without a drop falling, until the whole is appropriated by the bees. If very rapid feeding be desired, the net may be drawn out after the bottle is inverted, thus bringing the food more completely in contact with the perforated zinc, and enabling the bees to remove it in a wonderfully short time. The points to be attended to in adapting the perforated block to a bottle are, first to make the hole sufficiently large to admit of the neck passing freely in and out when enveloped in the neck; whilst the block itself should be of such a thickness that, whilst the bottle-mouth rests on the perforated zinc underneath, the upper side of the block fits close to the surface of the bottle. This is very important; because, if strange bees or wasps are able surreptitiously to obtain a taste of the forbidden sweets from the outside, serious injury, or even the total destruction of the colony, may very probably result from a combined attack, which few stocks are able successfully to resist. In conclusion, we may add that a long and very extensive experience warrants us in fully endorsing the conclusion of our able and esteemed correspondent "B. & W." that the inverted bottle is indeed the *ne plus ultra* of bee-feeders.]

EVENING THOUGHTS IN JANUARY.

(From the German of ADALBERT BRAUN.)
BY "A DEVONSHIRE BEE-KEEPER."

WITHIN my little garden
Stands also a bee-house,
And bees therein protected
From fly tomtit or mouse.
How quietly they're sitting!
And little trouble give,
Beyond the needful watching
That undisturb'd they live—
That all, indeed, are living
In strong unbroken health,
And, in the brood-nest hanging,
Consume their hoarded wealth—
That in the dwindling store-room
Sufficient stores remain,
Until the rape-platt donnett
Its blossom dress again!
Thus daily do I visit
My garden and my bees,
Neglecting thereby often
My dinner and my ease.
Thank God! they all were humming
Within their hives to-day;
Nor could I find a symptom
Of hunger or decay.
And yet what ardent longing
I feel, O Spring, for thee!
My darlings' gleesome frolics
Are happiness to me!
How would this anxious longing
Consume my very breast,
But for a little being
So full of love and jest,
In heat or cold that prattles
Around me ev'ry day,
And stills the throes of longing
By commune blithe and gay.
Ye bee-keepers can value
A joy that is complete;
It is my wife—the darling
Whose lips are honey-sweet.
With e'en the richest bee-stand
Were joy and pleasure gone,
If my heart's queen were wanting
And I left here alone.
Thus her I love and honour,
No difference have we,
But oft-times go together
Our little pets to see,
Her kisses sweet removing
All sorrow from my breast,
And honied joys surrounding
Proclaim us highly blest.

—T. W. WOODBURY, Mount Radford, Essex.

OUR LETTER BOX.

POULTRY DIARY (A. Barker).—Its publication has ceased. We are an interested copy of "Johnson's Farmer's Almanac," which may be had in a cloth binding for 2s., and we rule the blank leaves according to our own requirements for eggs, &c.

SPANISH COCKEREY LOST AT THE CRYSTAL PALACE.—"Not having received back the single Spanish cockerel which I sent to the Crystal Palace Show; and Mr. Houghton, although he has taken great trouble, having been unable to ascertain what has become of him, I am induced to inquire whether this sort of loss has ever happened to any other of your readers. It is true that a bird was returned to me, but it was totally unlike the one I sent. Mine was bred by me from birds highly commended at Manchester, was the pick of about fifty chickens, and was itself commended at the Crystal Palace Show. The bird returned to me was worth about 2s. 6d.—R. B. FOSTERS, Brentwood."

THE MANCHESTER SHOW PRIZE LIST.—The first prize for old Spanish and Duckwing Game chickens, we are informed, should be "John Martin, Claines, Worcester," and not "John Martin, Bingley," as stated in this Journal.

BOYS' SCHOOL (Pater).—We advise you to send your sons to Dr. Behr's, Winton House, Manchester. We know several youths who have passed excellent public examinations after being under his charge; and they all speak most highly of the kind household treatment of Mrs. Behr.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 43.9° and 32.3° respectively. The greatest heat, 58°, occurred on the 23rd, in 1834; and the lowest cold, 7°, on the 26th, in 1835. During the period 141 days were fine, and on 111 rai fell.

HINTS FOR RAISING A HARDY RACE OF CROSS-BRED HEATHS.

OST surprising is it in this age of botanical enterprise, with the high estimation in which gardeners hold Cape Heaths for decorating the conservatory and greenhouse all the year round, to find that no attempt has hitherto been made to cross them and their numerous garden varieties with the hardy European

kinds, so as to produce a perfectly hardy race suited to the open border. If the art were difficult, and the chances hopelessly rare, this might readily be accounted for; but as there are ample materials, and great facility, no fear need be entertained that a person with moderate skill, ordinary perseverance, and a slight botanical acquaintance with plants would fail. Individuals who follow such pursuits generally obtain more or less reward for their trouble, and abundance of that blessing to mankind, "the pleasures of hope," besides, the great gratification arising out of the unexpected accession of new and beautiful objects, the pleasures from which occur almost daily. When the prospects of obtaining such objects fail to be realised, anticipation yields the same balm to the mind, and thus, whilst it stimulates the operator to fresh action, also invigorates the animal powers, and increases the capabilities of enjoyment, for each succeeding set of seedlings always brings some interesting novelty which has been little expected. Mrs. Grant, of Laggan, sings, "What lovely prospects wait each waking hour, when each new day some novelty displays;" and as such novelties are almost sure to be realised by hybridisation, if patiently and attentively carried out, and as no one can be an enthusiastic cultivator of flowers without feeling desirous of seeing improvements effected, how better can such a desire be gratified, than by raising seedling varieties? Nothing can give greater pleasure to the lover of his garden than watching, through the various stages of their growth, his productions until they arrive at maturity, and burst forth to gratify the eye with their hitherto-hidden beauties.

It will, however, only be after a course of years, coupled with much care and perseverance, that the gardener will be able to bend the stubborn wild beauty to his will, and that the cross-bred plants will arrive at a state of perfection which never could have been anticipated when first the attempt was made to improve them, even by the most judicious use of the materials at

the hybridiser's command. And who can tell after all but that such efforts only help to do that which Nature herself has done oftentimes before without the aid of man? Still, care and cultivation uniformly develop certain qualities differing in each variety, which are only dimly perceived, or, perhaps, not at all seen in the wild or natural state, or only in such species as are capable of great diversity in their varieties. In Nature there are a system of development and a definite point of perfection, the approach to which constitutes improvement in each variety; and this is effected by crossing those varieties that have shown respectively the greatest advance in the direction desired, for the whole system abounds in varieties whose offspring is mongrel in race, uncertain in progeny, and variable in aspect, and from which circumstances alone fresh varieties are constantly produced, more and more developing qualities in some direction, and pointing to a standard which when reached would be perfection in that particular variety. Notwithstanding that less is due to chance than skill and judgment in the first instance, still the work of the hybridiser is simply to follow whither Nature leads him, selecting always that track in which there is the greatest promise of his securing the accomplishment of his desires.

The botanist considers hybridising plants as a sort of presumption to mend Nature, for he loves her for herself. A rustic beauty to him is "loveliest when least adorned," while the gardener loves Nature too, but not in her *deshabille*—for him she must be "clad in all her charms." The scientific man also considers hybrids as departures from Nature and interferences with the habits of plants, and calls them "Nature's bastards." Still "Nature is made better by Art, for that which adds to Nature is an art that Nature makes;" and the study of Nature does not lead to irreconcilable differences, but unity of purpose, for there is no difficulty in following the successive advances, or in discovering that there is no capriciousness in flowers, because those advances lead to correct results, and have real natural connections.

It, therefore, only requires skill and a moderate amount of perseverance to succeed in giving the hardness of the European Heath to the more tender ones from the Cape, and so produce an assortment of shrubs of great beauty for ornamenting the open border at all seasons of the year, similar to those which now decorate the greenhouse and conservatory. And there is no reason to suppose, from what has already been done with hardy Rhododendrons, but that success would crown the endeavours of all those who tried their skill in raising cross-bred Heaths, which would flourish in the open border, and withstand the rigours of our severest winters, like the beautiful little hardy moor Heath, *Erica carnea*.

The first and most essential point, therefore, to be attended to, in raising a race of cross-bred, hardy Heaths suited to the open border, will be to give a hardy constitution to the plants, by blending the hardness of the little moor Heath with some of the spring-flowering Cape kinds, and those hardy species, such as *E. tetralix*

ciliaris, cinerea, multiflora, vagans, and Mackayana, with the summer and autumn-flowering Cape ones, making the hardy kinds at first the male parent, for in so doing you not only have a large assortment of Cape sorts to experiment upon, but also the advantage of having them out-doors. It will, however, be very requisite for those persons who take up the subject in earnest, to obtain a full set of the hardy kinds and their varieties, and keep them in pots, so that the plants may be at all times ready in a portable form.

The process of hybridising plants being now so generally understood, it appears unnecessary to allude to it further than to remind the operator that self-fertilisation must be carefully guarded against, by removing the pollen-bearing parts of the flower before any pollen be dispersed, and that he must labour even more diligently than the industrious bee among his flowers, or his hives will produce no sweets. It may also happen that some of the first attempts at crossing the hardy European Heaths with the beautiful and more aristocratic varieties from the Cape, may prove failures, or that but little advance may be gained from the first crosses; still, by recrossing the hybridised seedling productions with a hardy kind, and more experience in the selection of sorts for trial, such difficulties will soon be overcome, and the result after the second generation prove a hardy race, for many of the Cape kinds may already be considered as half-hardy, bearing, as they do, several degrees of frost without injury.

In sowing the seeds and raising the young plants, the treatment should be in all respects like that of the hardy Rhododendron, and at no time should artificial heat be used to obtain or stimulate growth. Afterwards select, when the proper time shall arrive, the most promising kinds as regards hardihood for recrossing, until a thoroughly hardy race is established, when, as is the case with all mongrel productions, selection and cultivation will do much towards attaining perfection.

The cross-breeder, however, should at all times be guided by a comparison of results obtained from experience, and from such draw conclusions upon which to act, for mistakes are made, and will still be made, in the endeavour after advancement; and much will depend as to the value of what may be raised afterwards by attending to particular objects. In the present case, everything must be sacrificed for hardiness, and the varieties will afterwards be improved by selection and cultivation, like the offspring of all mixed breeds.—GEORGE GORDON, A.L.S.

BUDDING AND GRAFTING WITH A SELECTION OF NEW AND OLD ROSES.

THERE was a proper answer, and a very queer answer in the last Number about budding forced Roses. A gentleman down at Brentwood, where the eastern counties' farming begins to tell after leaving London, wrote to say he had a lot of Manetti Roses, and he wanted to bud on them from some of his forced Roses for two reasons—the first, to gain so much time, or say one season, if he did them now or up to the end of February. The second was a more valid reason—he was a good hand at budding, and could bud them himself; but as to grafting Roses, he had so little practice in it that he felt he was not quite well enough up to the mark of doing it; and the next best plan, of course, was to apply to the fountain head of practical knowledge in such matters. The answer he had was what tickled my fancy, and made me write about Roses to-day. Oh, yes! "Your plan is founded on scientific principle, and your plan and theory are both correct, and must succeed; but, after all that, the practice of the whole trade is against you." Now, that answer must have sprung from one of two very different causes. The gentleman from Brentwood must have begun his letter on the second page, and so put the Editors into their best mood, because they would have no trouble with it; or else they, the Editors, intended to show cause why there should not be more than two modes of proceeding. The common saying is, that there can be but two ways of doing or saying a thing—the right way and the wrong way. But here we have a different version of it. A plan and theory founded on scientific principle must, indeed, succeed unless very badly managed; but "the practice of the whole trade is against it." I always said that the practice of several in the Rose trade was not altogether good; but to say the whole practice of a trade is against a plan and principle on a plain scientific foundation, is just as much as to say there are two good ways of doing a thing against

one bad way of doing the same. And, as is always the case when the Editors have two strings to their bow, they make us writers draw one of them with no more to say than "mind the mark," and on this occasion it so happens that it is my turn to pull; otherwise the Editors, would keep Manetti and Morven as far apart as the poles of the earth so early in the season.

The first turn is, that there are two ways of budding Roses and ten ways of grafting them. The gentleman at Brentwood has hold of the second way, which is the surer of the two. He is about putting, or has already put, his lot of Manetti stocks into the forcing-house, forwarding them to the growth they would have naturally in the middle of May. The bark will soon "run," and so will the gentleman, and never stop until the whole are budded with the best new Roses—such as John Hopper, Beauty of Waltham, Madame de Chabillant, Madame Furtado, and Madame Crapelet, Louis XIV., Senateur Vaisse, General Washington, General Simpson, and Admiral Nelson, Victor Verdier, and Madame Vidot, and such like popular and much-prized kinds out of the newer Roses, together with a very select few of the older kinds, beginning with Madame Laffay, Géant des Batailles, Baronne Prevost, Duchess of Sutherland, Duchess of Norfolk, and down to Général Jacqueminot, which was an oldish Rose the moment Senateur Vaisse hoisted the standard; also a very few sweet-scented Roses, which no one likes to mention in these days on account of Manetti, which such Roses never want to be budded upon. I mean the old Cabbage Rose (the very best of them yet after all), the Crimson and Crested Moss, Boule de Nanteuil, Kean, Paul Ricaut and Paul Perras, Coupe d'Hébé (Her Majesty's favourite Rose), Chénédele, and "Lee's Perpetual," all sweet, sweeter, and sweetest.

Of course, he, the gentleman aforesaid, will bud all these, and some others, as near to the surface of the soil in the pot as he can manage to turn the worsted thread in tying on the buds; worsted being the best tie in the forcing-house, as it will keep moist of itself the whole time, from the moisture or vapour needed in the air in all such forcing. Having full command, now, over his handiwork, he will not allow one joint more to grow on the Manetti parts, but force the whole action of the roots into the one outlet of the new buds; then it is one sees the effect of forcing with 10° or 15° more of heat than out of doors in summer—there would seem to be more huckstering between the Rose stock and the bud, to see which could go first, as it were.

Now, and for two more months, the stock, even the excitable Manetti, will yield to the run of the new bud, on a pressure of from 55° to 60° of night heat, with that degree of moisture. Then, if March be a fine month, by the middle of April every one of the buds will have made shoots from 10 to 20 inches long, according to the sorts, and by that time, no doubt, the pots will be taken to the greenhouse, or at least to a cold pit, and if any bloom-buds come they will be instantly picked off. All this time not a leaf of the Manetti stock must be touched, all, as yet, consisting in merely stopping every effort to make more growth to Manetti; for, recollect, what the Editors say about scientific principle, all this work is based on that, and going at railway speed, to make up one whole season in advance.

Well, cold-frame work till all the bedding plants are out, and, last of all, give the spring-budded Roses their free liberty in the richest-made bed of loam and rotten dung that ever was made in the eastern counties. But, yet, that scientific principle has kept on the head of Manetti, and at the planting-out time the shoots from the budding are to be cut back just one-half their length, the balls entirely shaken off, and some shading will be necessary for the first ten days. The first effort of new growth will be at the top of the pruned shoots, and when the new growth there is three or four joints long will be the time to begin to reduce the head of the Manetti. Up to that moment poor Manetti has been doing the necessary work of that member of the Rose peerage for whom his head is to be cut off, and we shall see no more of him, for in these eastern counties they found the safety of giving burial to all Manettis on the occasion of cutting off the heads; and so it is, and if there is an inch of Manetti not buried, that inch will dispute for pre-eminence with all that are worked on it, and both would be crippled. So there is no need to follow further the fortunes of this batch.

But, how comes it that the trade never bud their forced Roses, or force the new Roses to have buds from? They do both, but they do it very differently, and make every bud produce a plant after all. If the trade were to wait till the bark of the stocks would "run" in order to bud, their customers would

bark ten times louder for the delay than they now do, and every one knows the barking is loud enough as it is. This I can tell to my cost, for I am obliged to buy every inch of Rose I grow, on account of my relation to Manetti, and though I went in for John Hopper as early as the middle of December, I could not obtain it for love or money; but I was lucky enough to procure Beauty of Waltham on its own roots.

All the nurserymen graft the new Roses as fast as they can make them grow the first year, and many, if not most of them, grow all their best Roses from cuttings both the first year and until they have a full stock of them; but the real new Roses are difficult to be had on their own roots the first season, and so I lost my chance of John Hopper for another year.

It happens sometimes that when one is cutting-up a new Rose for grafts there are some very small side shoots which are too slender for grafts; but being as good as so much gold they are struck as cuttings, and are soon as good as the grafted plants, and that was the luck by which I was enabled to procure Beauty of Waltham and some others of the same feather. Well, budding Roses is one of the easiest operations to learn; but grafting them is an easier process and a much safer way to make every bud tell for a plant; so there are two best ways of doing this part of the business.

The best way to bud a Rose in summer or winter is not to extract the bark and bud from the shield of soft sappy wood as some do, but to take the thinnest slice of the sapwood along with the bark and bud; then if the edge of the bark does not take at once, the soft woody slice behind the bud is sure to stick to the soft body of the stock and amalgamate with it for the flow of sap into the new bud, and it is on that same principle that a grafted Rose is more safe than a bud put in on the ordinary plan of budding. Grafting Roses is not like grafting Apples and Pears, it is more of an intermediate process between budding and common grafting; the Rose-grafters, merely take a thicker slice of wood behind the bud than is done in budding—say a thicker and a little longer slice, and one bud only; then the stock needs only a like slice to be cut out of it, and the new bud and slice to be nicely fitted to the part without tongueing or wedging: nothing but to tie on the slice. Supposing you took a slice of bark and wood off a branch, and cut across the bottom to take it out fair, would it not be easy to stick on the same slice again, and tie it round with some soft binding? Of course it would; nothing was ever yet easier to learn in this world.

Rose-grafting is quite as easy, only you take the slice from a different branch, which is all the difference. But clever practitioners do it still easier. They cut off the head of the Rose stock, and leave only a little stump out of the pot; from the top of this stump they slice off about $1\frac{1}{2}$ inch down, and make a cut across the bottom of the slice which leaves a notch there, and on that notch they rest or fit the bottom end of the graft slice, then cut the top end of the slice square with the top of the stock, tie, and clay; sometimes they do not clay at all, but it is more safe for ordinary people to put on a little clay for all kinds of grafts.

The best way to clay a Rose graft and all pot grafts is, to put a lump of clay in a pot saucer and as much water as will make it into a soft paste, like very thick paint, and with a little brush paint the stock and graft all round, then dust it over with sand, which will keep it from cracking, and all is finished. Gardeners make their own brushes for this work, a bit of soft matting tied on the end of a stick like a pen-holder is all they require. When you hear of people grafting Roses in-doors, the plan is still more easy. There is no pot or mould, only so many Rose stocks lifted out of the ground on purpose, and any of the ways of grafting will do. I am going to graft a great many Roses this next month merely for amusement, and to try two or three ways, the one against the other to find out which is the easiest and most sure. Most of my stocks will be six-inch lengths of any Rose roots that I can lay hold of, for, ultimately, I shall induce the grafts to root on their own account. D. BEATON.

PEAS—GREENHOUSES.

I MUST this week ask to be a seeker of information instead of being, as usual, in my small way, a giver of such; although, probably, the result of my questionings may be useful to other folks besides myself. In one of the reviews of the Great Exhibition just closed the reviewer remarked—there must be surely

some great mist over our eyes about diamonds, that fabulous as was their value it was not warranted by their appearance, that to his mind the imitations of the Koh-i-noor in cut glass were quite as brilliant, and that he questioned very much whether if one of them had been placed in lieu of the veritable gem half the crowd that pressed in to see it would have found it out. Of course this was a most heretical declaration, but I only mention it just to shelter behind while I make one as bad—namely, that there is, to my mind, as great an illusion on the subject of Peas. We have a wonderful variety—Peas as large as bullets, and as sweet as if they were sugared; Peas that grow 6 and 7 feet high, and others that only grow one and a half. But I must—turn me out of your company, oh! ye gourmets—express my entire abhorrence of the whole race of Marrows. I do not think there are any Peas that equal those we have in the first part of the season. Daniel O'Rourke, Sangster's No. 1, &c., I can eat and enjoy them; but when they are over, and these great hulking grenadiers come in, my Pea-eating diminishes in an inverse ratio, and I look forward to the coming-in of the French Bean as a positive relief. Now, what I want to know is, and will some one who does not blush for my want of taste inform me, whether it is not possible to have such Peas through the season, and, if so, what would be the conditions under which one might expect to have them? All through the summer at Paris you have the *petit pois*; and, I suppose, our Victorias, Ne Plus Ultras, &c., would be considered as only fit for the strong stomach of John Bull. As one must be now looking out for seeds for the year, I should be really glad of any information on this subject.

Then, again, I want a little advice on the subject of a greenhouse. My present one is all coming to pieces, and I want to put-up a new one in its place. It is a lean-to, and heated by a flue. Of course I want to put it up as cheaply as I can, and for this reason purpose having the top a fixture, no sashes, but simply bars glazed. I have in my mind the size I want, and most of the details; but I should be glad if some friend to small gardeners would say what is the best plan of ventilating. The house will be about 16 feet long and 10 wide, in a corner, so that the wall forms one end of it. It faces about south-west, so that it receives a good proportion of sun. It needs good ventilation, and that is one point I want information on. Then, with regard to glazing, I remember seeing, some two or three years ago, at the nursery of Mr. Wm. Paul a new system, which seemed to me much more economical than the ordinary one. The glass was laid on putty, and screwed into its place with screws on indiarubber bands. Will he kindly give his experience of the matter, and say how it answers, and whether frost affects it or not, and how it is to be done? I dare say such information is to be had, and has been given before; but then every year makes such changes and introduces so many improvements, that it is just possible one might reap the benefit of some more recent experience.—D., Deal.

CROSSING STRAWBERRIES.

I HAD intended, on seeing in my November part of your Journal the question put by Mr. Darwin about crossing Strawberries, to have replied, mentioning an experiment I had made in that way, but having occasion to go to the country for a time, I postponed doing so. It had gone out of my head till after my return, when I was again reminded of it by seeing two answers to Mr. Darwin's letter in the December part of your Journal. These answers do not exactly meet the question, neither does mine precisely, as I am now to give it. But, as the subject is one of high interest and referring to a tribe of plants among which I have been experimenting for many years, any item of information, however small, may not be without its use to some of your other readers, if it should be valueless, as I fear it may, to Mr. Darwin.

Having many years ago received from my friend Dr. Jameson, of Ecuador, seeds of a large-fruited Strawberry, cultivated at Quito as an importation from Chili, I sowed them and raised a very large-berried brood, but with fruit so insipid that I regarded them as utterly worthless. Having at the same time a very fine but intractable kind of Strawberry in my garden, called "Myatt's Pine," which after a time ceased to bear fruit, I be-thought myself of trying to infuse its delicious aroma into its robust congener from Chili; and I was induced to this the more from observing one valuable property in this latter species

—namely, its stout fruitstalk—so I made the cross and have now cultivated the progeny for two or three years. The insipidity of the Chilian parent is removed, and a considerable share of the Pine flavour communicated. The fruit-stems, too, are stronger than in the Pine. Plants are at Mr. Darwin's service if he wish for them. They are a good deal alike, yet there is one of a peculiar habit, very dwarf, and throwing off few or no runners, the fruit of which is globose, not angular, as is the case with most others of the batch.

It may not be uninteresting to Mr. Darwin and your general readers, to mention a result in crossing which I have not heard of being before detected.

In the spring of last year I made several crosses among Rhododendrons with the pollen of *R. Nuttalli*, the largest-flowered and noblest of its race. Observing the unusual size of the seed-pods of this cross, I took measurements to-day of their dimensions, and beg now to note the respective measurements of these pods as borne by *R. Dalhousiae*. The largest pod I can find of *R. Dalhousiae*, not crossed, is $1\frac{1}{2}$ inch long by $1\frac{1}{2}$ in girth.

Of three pods of *R. Dalhousiae* crossed with *R. Nuttalli*, each is $1\frac{1}{2}$ inch long by 2 inches in girth.

One pod of *R. Dalhousiae* crossed with *R. longifolium* (rather a robust species, but not nearly so robust as *R. Nuttalli*), measures $1\frac{1}{2}$ inch long by $1\frac{1}{8}$ in girth.

The seeds of the above crossed with *R. Nuttalli*, one of the pods of which, pulled some days ago and opened to-day, appear to be as abundant as they are large, those of one pod nearly half filling an ordinary-sized teaspoon.

Has this result of enlarged fruit or seed-vessels ensuing from crosses effected by larger species than the seed-bearer, been before observed? With me it is too marked to be a matter of chance. —ISAAC ANDERSON-HENRY, *Hay Lodge, Trinity, Edinburgh.*

[Mr. Anderson-Henry enclosed a leaf of the cross-bred Strawberry. It is very peculiar in form, the leaflets being compressedly-circular, or, as botanists term it, oblate-orbicular. —EDS. J. OF H.]

CELERY CULTURE.

AS I have been more successful than "HUDDERSFIELD," I will detail my mode of growing Celery.

I sow in pans about the middle of March, and place them in a little heat, close to the glass. When ready for pricking-off, I transfer the plants to a frame in which Asparagus has been forced, and in which the heat is almost exhausted. When there for three or four days, I give the bed a slight watering, if required, and then prick-out the plants and water, keep them close for two or three days, and shade if requisite. When they take hold and commence growing I give plenty of air, hardening them by degrees, and ultimately removing the sashes altogether.

Watch for a favourable opportunity to plant out. If the sun should break out shade with some spruce branches. I never allow the plants to receive a check. That I consider is the most essential point in Celery-growing.

For my principal crop I grow from twelve to fourteen hundred, and the man that takes them up for the kitchen tells me that he has not met with half a dozen bolted plants up to this time, and

I an answer for the Celery being as crisp and solid as any one could wish for. It was not so large as it should have been, but that I attribute to the maggot or blotch on the leaf, which was very bad, and equally bad on the five sorts that I grew. I had some quicklime and soot dusted on the leaves, but I was too late in doing it, as the mischief had been done; but it prevented it from becoming any worse.

I plant single rows in a trench, the after-treatment is similar to that of "HUDDERSFIELD'S."

The sorts that I have grown this year are—Cole's Superb Red Solid, Cole's Crystal White, Seymour's Superb White Solid, Bossam's Pink, and Incomparable Dwarf White. The last is, indeed, incomparable, for none of the other sorts can compare with it for crispness and solidness. It is small, but we do not want great clumsy stalks for a gentleman's table. Bossam's Pink comes next to it for quality.—A. S., *Staffordshire.*

I NOTICE in your Journal of this last season many complaints about a failure in the Celery crop. Now, I do not know how it is, except that Ireland possesses a better climate, &c., for growing that favourite vegetable; but this I know, that I never had a better crop, and my man makes no fuss about growing it. The

way he does is as follows:—During the season all the droppings of the cow-house which pass through the grating or gripe are wheeled into the garden, and accumulated there ready to be put in the trenches, when the Celery is about to be planted, in a layer of about 6 inches thick, and mixed a little with the soil.

The seed is sown on a slight hotbed amongst late Cauliflowers about the 1st of March, and after the young plants are well up the lights are taken off, and the plants allowed to spindle-up to about 6 inches. I do not think pricking-out is of much service, as the taller the plants are the sooner they may have their first moulding; and the earlier they are planted and moulded the better Celery is obtained. I make about three mouldings or earthings do. I do not dribble, dribble-up a little now and then, but give a regular good moulding—say of 4 or 5 inches at once. I pull the plants out of the seed-bed without any ball, just keeping what soil remains to the roots, and in this way the man by a glance can see whether any grub or canker worm is on the roots.

I always sow the old kinds, Cole's Crystal White, and Cole's Superb Red, and have no cause to be dissatisfied with them. I have 14 inches of good, clear, solid stalk, 2 inches in circumference, and entirely devoid of stringiness or soft heart. I always choose the stiffest part of the garden for growing Celery in. I do not use either liquid manure or soap-suds, as we here have always plenty of Nature's liquid falling upon the plants.—HIBERNICUS.

DISEASE IN CUCUMBERS.

THE Cucumbers were planted out in pits, heated by hot water, last year, before I came here, and the trellises were nicely covered, the plants looking healthy, moderately strong, and showing abundance of fruit. My predecessor told me how they would go, and well I know it. I could scarcely find one out of fifty from which I could manage to take a piece out that was fit to eat. I have tried a great many sorts, but they all go the same here. They swell till they are about 5 inches long, then they curl up like a ram's horn, and a sort of gum issues from all parts of the fruit. If we let them hang long, they will drop a bit at a time, and smell like a rotten egg. The soil we have used is good fibrous loam, a little decomposed dung, and leaf mould, &c. I keep them neither too wet nor too dry at the roots, and I use the syringe very sparingly overhead, but sprinkle water over the floor and pipes when shutting-up, if open. I generally have the house at 70° by fire heat in the day, and from 60° to 65° by night. I find the Cucumbers just the same in spring and summer on dung-beds. If you know of any preventive I should feel obliged.—A CONSTANT READER.

[Yours is one of those inveterate cases of Cucumber disease which seem to have hitherto baffled all attempts to effect a cure, or suggest a preventive. We have, however, submitted the matter to one of our regular correspondents, who writes us as follows:—

"I am sorry to hear of the Cucumber disease appearing in your correspondent's winter fruit, and I only wish I could with certainty suggest a cure. This, unfortunately, I cannot undertake to do, as I have had no experience of the disease since 1850, when I had it amongst some winter fruit exactly as 'A CONSTANT READER' complains of, and, subsequently, crop after crop of frame fruit became likewise affected, and even those on ridges were similarly attacked, though not so severely, perhaps, as those under glass; but the Cucumber crop of that year might be safely pronounced a failure.

"Of course, the season did not pass over without my trying several experiments, with a view to arrest the evil, but they were so far unsatisfactory that I believe no single plant produced fruit entirely free from disease. Nevertheless, some were more diseased than others, and I was led to the conclusion, that although the disease is a malappropriation of the juices of the plant, which instead of producing fruit, furnished a disgusting-looking glutinous tumour almost at every spine, yet I could not but believe that the disease was also in many respects contagious or infectious; for although I tried plants on soils as widely different from each other as sand from clay, the disease still existed, differing, however, in degree. This and other reasons led me not to attempt Cucumbers in winter the ensuing season, but to try growing them the following spring and summer in a compost the same as that in which they seemed least affected with disease the preceding season. Accordingly

some extreme mixtures were made, in which charcoal dust, mortar rubbish, and other materials entered freely—not all alike by any means, but there were several which at other times I should have considered odd and unsuitable; still the exceptional nature of the case warranted this at the time.

"The result was crops of fruit, not so fine certainly as have been grown on more favourable mixtures, but the fruit was healthy and clean, and my object was attained. This, I may observe, was in 1851, and I do not think we had a diseased fruit until very late in the summer, and am not sure there was any then, and since that time we have been free from the disease.

"I have heard of its visiting other places in a like manner, and I believe it to be more prevalent in winter-grown fruit than in those grown in summer. This is easily to be accounted for: the plant at the latter time is more robust, and capable of so preparing its juices as to feed its legitimate objects; whereas, the energies of the other go to feed an incurable abscess, and whether you grossly feed or half starve the patient, he cannot long survive when the stomach remains so long out of order. Plants like human beings, however, benefit much by inhaling a more suitable atmosphere, and it is possible 'A. CONSTANT READER'S' plants may partially recover when more sunny weather sets in; but my experience leads me to think they will be too far gone then, and the fact of their being affected on dung-beds in summer, both in his case and in my own, leaves little hope of a cure until the growing of Cucumber plants has ceased for a time, so as to allow all traces of that contagion or infection, which I believe has a something to do with the matter, to die away; and a fresh beginning made at a proper time when there is a good chance of success, will most likely result in healthy plants, and clean and wholesome fruit.—J. ROBSON."

COCOA-NUT FIBRE DUST FOR PROPAGATING PLANTS.

THE tide threatens to overflow the tanks already in the matter and manner of applying the cocoa-nut fibre dust over open tanks for propagation. They told me at Kew, last September, ten times more in favour of the stuff that way than I put on record, because I missed the head propagator, and, also, because I intended to go to Kew on purpose for this one object, some time at the height of the propagating season. Meantime, and to stem the tide of inquiries about how the refuse is to be kept out of the tank, let me come, or become, a correspondent, and put a few simple questions to ladies like "A. H.," in a shade of mauve pink paper, and to gentlemen like his reverence down about Salop.

How is it that the coffee "grounds" are kept back, and that tea leaves do not get into breakfast-cups? The way those feats are achieved, or a way like it, ought certainly to keep back this refuse from a tank of water under it, and yet let up the vapour to keep the refuse constantly moist.

Or, how do the brewers down in the country manage to keep the "grains" from going down from the mash-tubs into the cooler? Surely the ingenuity which has accomplished such difficult engineering processes could suggest some simple mode of effecting this; for to tell the truth, I quite forgot to ask the gardeners at Kew how they managed to surmount the difficulty, but I must take a note of it and make a diligent inquiry.

But I can tell how our clergyman, the Rev. Edward Phillips, managed this winter to prevent this refuse from going down in his propagating-pit, and in another hot pit, which may be 30 feet long, and 5 or 6 feet wide, all heated by Mr. Jones's cannon boiler.

The reverend gentleman sent for a load of the cocoa-nut fibre bristles, not the dust of the refuse, paid 10s. for the load on the spot, so it must be worth over three times more money than "our dust," and so it is, for it is found to be better than hair in all stuffing where hair is used, and in all kinds of plaster and mortar, and such-like. Well, 3 inches of this bristly stuff, put over open rubble, is pressed into 1 inch in thickness, which keeps back sand and mould, and lets up hot vapour in abundance.—D. BEATON.

SEA-KALE.

FOR Sea-kale to be in the same bed for ten years as "P. M.'s," and prove profitable in the year 1863, is taking us young men by surprise, who have for their motto "Upwards and Onwards."

Sea-kale, like all other strong-growing vegetables, is very fond of liquid manure at midsummer; but I never before understood that it cared for it at Christmas, nor any other plant wanting foliage. What would Grape-growers say if Mr. Thomson, in his admirable treatise on the Vine, advocated giving liquid manure to the Grape before a leaf was to be seen on the rods? Though the one is a fruit and the other a vegetable, both should have leaves, at least, before a stimulant in the shape of a liquid is brought into use.—H. KNIGHT.

NEW GRAPES ON NEW-YEAR'S DAY.

YOUR correspondent, James Fowler, Harewood Gardens, seems to question my statement doubting Mr. Thomson's being the first to raise new Grapes on New-Year's day, because I did not send any to be inspected before the 10th of February, 1862. Now, for the "why." I might have sent sooner; but, if he will remember, that was the time the question first became discussed in your columns, or in that of your contemporary. "Next," because I never show Grapes or any other fruit in London.

I herewith send you a small bunch of new and old Hamburghs for your opinion, and may state I cut some of both on the 1st of January this year.

I have at the present time hanging—Barbarossa, Lady Downe's, West's St. Peter's, Muscat of Alexandria, and Charlesworth Tokay. I have no word at the present time to say which are the best, but will leave that to abler hands to judge. To show that the idea is not new of having Grapes so early, I may mention that I saw at this place, some few years since, Grapes ripe on the 1st of January, and they had had them some years before then, which statement, should my predecessor see, he can vouch for.—J. E. F., *January 12th.*

[The bunch of new Grapes sent by "J. E. F." was a very fine one, short, and well set; the berries large and as black as sloes. They were not, however, quite ripe, having rather a too-marked acidity about them; still they evidenced on the part of "J. E. F." very high gardening skill. Accompanying the fruit was a leaf which measured 17 inches broad, and 17½ inches from the point to the margin of one of the lower lobes! It was like a rhubarb leaf for size. The bunch of old Hamburghs had decidedly the advantage in flavour; they were considerably shrivelled and had begun to assume the raisin form.—EDS. J. OF H.]

I WAS rather surprised a few weeks back at seeing in your Journal a communication from Mr. Anderson, setting up the case of Mr. Thomson's having new Grapes on the 1st of January as unprecedented. I would have taken no further notice of the matter, only from seeing that there is some doubt still of others having done the same.

I have little doubt there are many cases of the kind in the country, if they were made known. I myself cut some good new ripe Grapes at Christmas, some sixteen or seventeen years ago. I can see no reason why any one who is allowed the means should not have done so for years back. In fact, I consider it much easier to have new Grapes in December than in March. Of course, the Vines require a season or two of preparation.

Your correspondent, Mr. Fowler, need have no doubts about "J. E. F.," of Knowsley Hall, having ripe Grapes on the 1st of January, for it is well known in this neighbourhood that the late gardener at Knowsley, Mr. Jennings, who is well known as one of the best gardeners in the country, had regularly for many years back a large house of new Grapes ready by Christmas, and Grapes of such a quality as would not have disgraced our great London exhibitions in May: therefore, with the means already provided, the present gardener would, with ordinary care, have but little trouble, so far, in following the footsteps of his predecessor.—J. SKENE, *Garswood, near Warrington.*

ESTABLISHING A ROOKERY.

IF "GATLEY" will take the top of an old bee-hive and fix it firmly as high up as it can be placed in one of his Elm trees, I think he may succeed. I did so some years ago and the rooks had young ones in it for two seasons, but they were stolen each time, so that I did not succeed after all. The trees were nearly in the centre of this city.—D., *Lincoln.*

GARDENIA AND POMEGRANATE CULTURE.

THE following hints are in answer to the inquiries of an Irish subscriber, and refer to the two hardier kinds—radicans and florida—the first growing compact as a dwarf bush, and the second rising more upright as a larger shrub; both producing large, double, white, sweet-scented flowers; and both coming to us originally from the flowery land of China.

1. *Propagation*.—Any time during the summer will do; but from the 1st of March to the middle of April I consider the best, as the plants will then be well established before winter. Small shoots, about 2 inches in radicans, and 3 inches in florida, of nearly a season's growth answer well placed in well-drained pots, in sand and covered with a bell-glass. These pots may stand on the surface of a mild hotbed for a fortnight or three weeks, and then be plunged in a bottom heat of 80°. If the bottom heat is from sweet tan, or dung and leaves, no bell-glass will be required, as the vapour from the dung, &c., with a thin shading in bright sunshine, will be quite sufficient to prevent wasting-perspiration from the cuttings. In such a place the cuttings will root quickly, and then should be potted-off and placed back again in the same place, kept close at first, and air given as the roots work freely into the new soil. Then nip out the point of the plant to make it bushy; and if a small 60-pot was first used another shift may be given into a 54 or a 48; keep growing with heat and moisture, and give more air in autumn that the plant may stand cooler in winter. After a second summer's growth the plants will be large enough to bloom in the following spring.

2. *Soil*.—This should be heath mould and loam, and a little sweet leaf mould and silver sand. The heath mould should preponderate in the first shifting, until for middle-sized plants there should be equal portions of each. For large well-established plants fibry loam should take the preponderance; and as soon as the plants are intended to bloom, not only should the drainage be ample, but the potting should be done tight.

3. *Time of Potting*.—For great success this is a matter of importance. Good-sized established plants will do well several years without repotting; but still when convenient it is as well to give the plants fresh soil, if no larger pots are used. The best time to do this is after fresh growth is taking place after pruning. Then pick or shake away a good portion of the old soil, use fresh soil well aired, plunge the plant if possible in a mild hotbed, water with water at 80°, and keep rather close and shaded until roots and tops are growing freely.

4. *Pruning*.—This should be done as soon as the plants are done flowering. The radicans will generally need but little pruning. Frequently young shoots will be growing before the flowers quite fade, and then the cutting-out of old pieces to give these room will be the chief pruning. Florida will need more of the knife to keep it in shape. The object in pruning is to obtain as many shoots all over the plant, as equal in strength as possible, as there is room for, and which will not only be strong enough, but ripe enough before the end of autumn to produce flowers at their points next season.

5. *General Treatment and Position*.—I will suppose that the plants have done flowering in June, and that they are standing in a warm greenhouse. After dressing or pruning, and syringing overhead, the plants may stand a few days, and are then taken to a hotbed. Here they remain on the surface for a few days, and are then, if possible, plunged in a bottom heat of 80°, the place kept rather close, and the plants syringed evening and

morning, and a little shade given in the middle of the day. After pruning some plants may have enough of young shoots, and in their case top-dressing or repotting may shortly be done. In the others, as soon as fresh growth is proceeding repot and encourage this growth, giving more air by degrees as the shoots become pretty equal in strength. The next object is to harden them so as to cause the flower-buds to set. About September air should be given liberally and plenty of sun, and by the middle of the month the pots should be kept free of the plunging materials—in fact, a cold pit would then do as well as a hotbed, and in such a bed with a hot-water pipe, or in a greenhouse, they may stand pretty close all the winter in a temperature averaging 45° at night; and during that time the soil should just be moist not wet. When it is desired to start them into bloom in spring select those first with the plumpest buds, and set them in a hotbed on the surface, where the temperature will range from 50° to 55°. In a fortnight the pots may be plunged in a temperature of 80°; and the top heat may average 60°, with a rise from sunshine. As soon as the flower-buds are nearly expanded raise the pot out of the bed. In a few days move to a drier atmosphere, and then in a few days more the plants may be moved to the greenhouse, in a rather close place, and where the temperature will be from 45° to 50°. Here the bloom will continue

much longer than in a hot pit or stove. After flowering the pruning, potting, &c., must be proceeded with as already detailed. These plants, provided they obtain a growing, a ripening, and a resting period, will do pretty well without a hotbed; but the hotbed treatment is not only the most successful, but does much to keep the plants in a clean and healthy state.

6. *Watering*.—When in bloom the colder the place the less water will be required, and that should be warmer than the house. When resting little water will be required, but the soil must not be dry. When growing freely water will be needed rather plentifully, and manure water then will help much. After sunny days the syringing of the foliage will be relished. In autumn no more water should be given than will do to keep the leaves from suffering.

7. *Insects*.—Green fly is apt to appear on the flower-buds when swelling, and also on the very young shoots, and a little tobacco smoke is the best remedy. Thrips and scale are also apt to assail them, but the hot vapour from fermenting material is the greatest enemy to such depredators as these.

Such a fine variety as *Fortuni* may have exactly the same treatment, but the temperature in winter should not be below 50°; and for such tropical kinds as *Devoniana* and the long-tubed *Stanleyana* it should not be lower in winter than from 55° to 60°. These latter could not be managed well without a stove; the former, to which I have chiefly referred, can be grown in fine order with the assistance of a greenhouse and a hotbed.

PUNICA (Pomegranate).

We are glad you have succeeded so well with this in a pot, though you failed with it against a wall, especially as respects its blooming. Perhaps the plant when against the wall was scarcely old enough to bloom freely. From all I have seen of it, single and double, I consider the Pomegranate to be rather hardier than the Myrtle, and when once established the treatment of both is very much alike. When against a wall the Pomegranate delights in soil light rather than stiff. When in a pot, and especially the double-flowering variety, it delights in soil more stiff and rich. To secure free-flowering, the training and prun-

Specimen *Gardenia Stanleyana*.

ing should be regulated to obtain a great number of slender shoots, as it is from them, and at their points chiefly, that the little bunches of flowers come. All rank shoots should either be removed or shortened. Against walls, therefore, the shoots should be spurred. In fine specimens in pots grown to a single stem, the head must be managed in a similar way to secure abundance of these spray-like shoots. Such specimens in pots, if the pots were mulched, would be safe enough in a shed in winter where little frost could enter, and when from 6 to 9 or more feet in height, they make pretty objects out of doors in summer. The single kinds are easily increased by seeds sown as soon as the fruit is ripe; also, by cuttings and layers, and the double and dwarf kinds by grafting on the single kinds.

R. FISH.

The highest reading of the thermometer in the shade occurred on the 29th of May, 72° 0; lowest ditto on the 4th of March, 19° 0. The greatest quantity of rain that fell on any one day in the year was on the 4th September, when 2.43 inches fell in the seven hours preceding 11 P.M. of that date; barometer at 29.301 inches; wind, W. The aggregate rainfall of 1862 is below the average of the last five years, and 9.45 inches less than 1861. It fell in small quantities at a time, and extended over a greater number of days than in the year last named. The temperature, especially of the summer months, was likewise considerably below the average. It was this low temperature, and the continued showery weather, that rendered the summer of 1862 so disastrous to gardening.

Kitchen-garden crops of all sorts have either been entire failures or most indifferent in quality. Spring-sown Onions were, in a majority of instances, complete failures. Carrots little else. Peas and Beans ran terribly to straw, the pods (legumes) filling indifferently or not at all. Kidney Beans never grow above 5 or 6 inches high, and never yielded a single dish

Celery I am almost afraid to speak of. It certainly is the worst crop I ever grew. Out of some 900 plants I believe there are 850 of them bolted. The White sorts are worst in this respect; the Red are a little better. I cannot account for it in any other way than by supposing it to be the result of the untoward season, as it was treated the same as in previous years.—
J. DUNN.

ORCHARD-HOUSE FRUIT.

WE received some time ago specimens of the Newtown Pippin Apple and Winter Nelis Pear grown by George Wilson, Esq., of Gishurst Cottage, Weybridge Heath. On former occasions we have had frequent opportunities of speaking of the success of Mr. Wilson as a cultivator of fruits under glass, and now we are enabled to lay before our readers additional proofs of his skill in this branch of horticulture. The specimen of Newtown Pippin measured $13\frac{1}{2}$ inches in diameter, and was of a fine uniform pale yellow colour. Unfortunately it was seized with an attack of that mischievous fungus, so prevalent this season, before we had an opportunity of judging of its flavour; still, from what we saw of the Melon Apple and Northern Spy grown by Mr. Wilson in former years, there is no doubt that the Newtown Pippin would also have been fine. The Winter Nelis Pears were among the finest we have seen, the largest weighing $5\frac{1}{2}$ ozs. They were very handsome, and the flavour was exquisite.

POTTED PEACH AND NECTARINE TREES IN AN ORCHARD-HOUSE.

SUPPOSING Peaches and Nectarines in pots to be three or four years old, to what extent should they be pruned in March? The trees in question have been pinched-back in the last summer three times, according to Mr. Rivers' plan, and the shoots made since August 1st are from 12 to 18 inches long. The writer is aware that a small portion of last year's shoots must be shortened to three or four eyes. His question refers to fruit-bearing branches of the present season.—SUBSCRIBER.

[If the trees have made shoots since they were pinched-in, "from 12 to 18 inches long," these shoots should be shortened to about 9 inches, taking care to prune down to a triple bud, or a single leaf-bud. If there are too many of these shoots, so that the tree is likely to be wounded when the leaves are on them, some of them should be thinned-out with a sharp knife, leaving no spur, but cutting them out close to the branch.]

EFFECT ARISING FROM DRAINAGE.

HAVING lately visited a friend on the edge of the fen country, I heard a most singular and to me unaccountable statement of a supposed fact, unchallenged and evidently believed by all present. It was to this effect.

Many persons living could remember fields in which the peat soil when they were young was 15 or 16 feet in depth, and in which a crowbar planted perpendicularly would soon bury itself; that in ploughing these same lands now, the clay was often brought to the surface, the peat, or bog soil rather, having all disappeared except a few inches, and yet that the surface of these fields was as high relatively to surrounding objects—for instance, canal-banks, lock-gates, roads, and highlands as they are called, upon which the towns and villages were built—as before the disappearance of this large amount of soil.

On my asking how they accounted for this phenomenon, they all agreed the clay subsoil had risen in the same degree that the surface had disappeared, and attributed it to the same cause—drainage. Being equally unable to controvert or explain this statement, I agreed to refer the matter to you for your opinion. Does wet clay increase in bulk when deprived of moisture? I had always thought the contrary, but we wait your decision.—
J. R. PEARSON, *Chilwell.*

[There is a well-known story of Charles II. enjoying the joke of puzzling the Royal Society by asking, "Why a vessel of water weighed no more when a fish was put into it than it did before, though no water escaped from the vessel?" The joke was ended when one of the members said, "Who has proved that it is so?" We, following that member's example, must ask, In any place known to have lost 15 feet of peat, is the surface

of the clay beneath raised 15 feet, so that the soil's surface retains the old level with surrounding objects?

It is quite possible for small depths of bog-earth to disappear in consequence of drainage, and yet the soil beneath to appear as high as before such disappearance, because the banks around the enclosure, if resting on the bog-soil, would sink in proportion as that bog-soil sunk.—EDS. J. OF H.]

PITS, AND THEIR FAILURES.

It is very unpleasant for people of hopeful or sanguine temperament to hear of crosses or failures in matters where they experience or anticipate success. I am not, therefore, surprised to find that my former remarks about small pits should call forth words of disapproval on account of the doleful and discouraging character they bore. Still the facts are as stated, although the deductions might not be the best. It is easy to imagine how the most inappropriate and badly-designed structures might not only be turned to good account, but that results of a more than ordinary character might be produced from them in the masterly hands of Mr. Fish, in the same way that an eminent chemist, in his early days as an experimentalist, produced wonderful results from the use of tobacco-pipes and other crude appliances, that few ordinary men could or would use. I can also understand how a clever amateur may work a small pit to advantage, where another would be unable to make anything of it. And it is to this same cleverness that some little merit should be awarded; for if every one who undertook the management of a pit or greenhouse could manage it to perfection at first starting, where would be the great merit, or where the superiority of one gardener over another? It is just to allow that readers are to a certain extent acquainted with the subject treated on, and, doubtless, most of the readers of THE JOURNAL OF HORTICULTURE are well informed in gardening matters; but then it is possible to allow too much, and as a proof that I have not recounted all the mishaps that have occurred with regard to small pits, and that there are people in the world who do take such matters in hand without proper thought and care, I will relate one or two more instances of failure. One man built a turf-pit of 20 feet by 6 feet, and 4 feet high at back, furnished it with a brick stove and flue, part brick and part pipes. The first winter, having spent 12s. for coke, he did not keep a single plant of 500 Scarlet Geraniums—the stock put into the pit during the autumn. Another built a good, sound brick-pit of eight lights; and finding that it did not answer his expectations, and that he could not perform wonders with it at first starting—like a person buying a fiddle under the impression that with it he is buying an ear for music and a talent for playing—he gave up in disgust all care about it. Another built a pit of wood 6 feet high at back, 18 feet long by 6 feet wide, as near as I could judge from sight. This also was furnished with a brick stove and flue. The man was both ingenious and persevering. He tried many methods of making it profitable and useful, but with only partial success, for of all garden structures these small places require the most constant and watchful care. A change in the weather will sometimes unexpectedly make a fire burn up clear and strong, endangering the lives and health of the plants, and where a man cannot always be on the spot, as is mostly the case where such places are built for recreation, he can scarcely give them the attention required.

I could give other instances, but it would be only a waste of space to do so; I will therefore merely observe that I have myself had the care of a small pit heated with flue-pipes, and made it answer all the purposes for which it was intended, and in a way that would to many be perfectly satisfactory; but not so to me, since, being in the habit of weighing the cost and labour with the results, the latter would lose considerably in comparison with those of a pit properly furnished with hot-water pipes, &c. Nor would the hot-water pit want half the care and watchfulness required by one heated with a flue.

I should never for a moment object to a good-sized greenhouse being furnished with flues, for some of the best plants and best fruit have been grown in houses so heated. Nor would I attempt to discourage any one from trying to do his best in the way of cultivating plants. It is rather for encouragement that I would caution the inexperienced against being misled by the notion, that because a clever and experienced gardener can produce good results from barely adequate means, they have only to become possessed of like appliances to be able to do as

much. If a person's means enable him only to build a pit, why not be content at first with plants that are easily grown? or if he have only a frame, is there less merit in filling it with healthy-looking Intermediate Stocks, or choice Picotees or Pansies, than in giving himself no end of labour in trying to keep tender plants, which at best do him little credit?

In this neighbourhood there has been of late years too much attention given to plants of warmer climates—that is, by the poorer horticulturists; while the equally pretty and useful plants that will, in a great measure, stand the rigour of our climate, and are far more easy to cultivate, are scarcely thought of. This has been the reason why many whose means did not allow of building a greenhouse have substituted a pit, and not finding the result up to their expectations, discourage the attempts of others.

In referring to my former remarks (which probably bear a more melancholy character than I intended), "R. F." says that the mishaps there enumerated were more the result of simple mistakes than of necessity. He was right. When a man builds a pit without any thought or care of what he will be able to do with it, he makes a great mistake. If he burns his plants by over-heating, he makes a mistake. If he builds the flue so that the smoke and gas come through, he makes a mistake. In fact, all failures are the result of mistakes; and it is when a man is able to avoid mistakes that he can successfully cultivate plants. Again, "R. F." says there is no necessity for poking your fingers into the parlour fire on a cold, frosty morning. I for one should be very careful not to approach the fire with my hands, were they very cold, for I have experienced that sensation caused by the sudden reaction in so doing, and do not wish to experience it again; although it is a common occurrence to see people rush to the fire, and almost, if not quite, poke their fingers into it, and many of them have to smart for it afterwards. This is not unlike those who rush too thoughtlessly into pit-building.

Why I mentioned charcoal as a good fuel for heating—a small, pit, is because a very small fire may be kept going with it, and in some places it is comparatively cheap, although here it is very dear; still I may be wrong. But this I do know, that I have kept the frost out of small greenhouses by means of a small cylindrical iron stove in which charcoal was burnt; the stove being placed inside the greenhouse, and so arranged as to burn slowly.

Some years ago the wet got into the roof of a brick-built shed; the rafters rotted, and the roof had to be taken off. At my desire a glass roof was placed on instead. There was no stage put in, but the place was soon filled with Oranges, Camellias, Azaleas, Neriums, and such plants. They have always done well, and grown as if the place suited them exactly, and I have used no means of keeping out frost but a charcoal stove, and this has answered the purpose. Makeshifts are very well where a gardener is always near to look after them; but makeshifts are not exactly suited to those who pursue gardening as a recreation, for they often involve such an amount of labour as destroys every semblance of pleasure, unless labour be regarded as a pleasure.—F. C.

WALKS.

(Continued from page 785.)

WALKS MADE OF BROKEN STONE OR BRICK.—With the exception of walks formed of gravel, and, perhaps, ashes, the above-form the most important materials of which walks, public or private, are made; and the comfort which walks of this kind present is visible in most country turnpike roads, where the pedestrian often prefers the middle of the road in clear weather to the prepared footpath, even when the latter is good. But turnpike metal, as the stones are called, will not easily of themselves form a good footpath without the aid of wheel carriages; therefore, however good they may be in forming the foundation, something else must be used at top less hurtful to tender feet. The same kind of stones may, however, be broken smaller, and in that condition they form a very good surface by rolling, &c. It not unfrequently happens that the inmates of workhouses are employed in breaking stones to the size required, and in such cases they are to be had at a much more reasonable price, than when broken by those earning proper wages. The best stones I ever saw used for this purpose, and which formed about the best walk I ever saw, came from a lead mine, the hard, white-coloured stone containing the ore being crushed by machinery until the particles were not larger than boys' marbles, but, of course,

angular. This refuse stone, being all about one size, formed an excellent surfacing to a walk, the white clean colour adding to its general appearance. I believe similar broken or crushed stone is to be had where mining of other kinds is going on; and where machinery exists for the purpose of crushing such stones it could easily be made to perform the same office to some kind that was well adapted to walk-making. The chippings of a stonemason's yard are also often worked-in; and I have more than once made a tolerably good walk of what might be regarded as little else than rubbish, some of the stones being as large as a man's head, intermingled with mortar siftings, chippings of brick, stone, and fragments of anything else, with a fair proportion of dirt, shavings, and straw. The two last-named articles, however, were, in a great measure, taken out. This heterogeneous mass was wheeled into a walk, the foundation of which was deep enough to receive and bury the largest stones; and, beginning at one end, every time a couple of barrow-loads were tipped against the preceding mass, the large stones were raked to the front, so that nothing was left in the depth of the rakes' teeth but such fine matter as would pass through the teeth. A good rolling, traffic, and heavy rain, consolidated the mass into a very good walk—certainly not equal to the best-made gravel walk, but good and firm. The same mode of proceeding may be applied to other substances as well, nothing making a more compact walk than plenty of mortar rubbish mixed with the other material. The walk alluded to above had a little of this admixture, as well as the other things mentioned. A very good and pretty walk may be formed sometimes of waste soft bricks crushed-up. Such as are unfit for building purposes, and break easily, may be used in this way, as likewise may all old or waste bricks, and, in fact, almost anything of sufficient hardness to hold together; slaty substances, however, not being good. Stone-shatter, and stone of all kinds, may be used for the bottom. Some kinds, however, are better than others, as will be shown hereafter.

WALKS OF GRAVEL.—This is unquestionably the most legitimate and best of all materials, and, being tolerably widely spread, is available in most places. It differs, however, much in quality; and notwithstanding all that has been said in its favour, the best kinds have their faults. The great secret in a good gravel walk is plenty of traffic upon it: certainly not the continual wheeling of barrows all in one place, but a well-spread company of pedestrians—such, for instance, as those who use and consolidate the park walks in London and elsewhere. It is not fair to attribute the smoothness of these thoroughfares entirely to the gravel they are made of, for it is the multitudes which daily pass over them that make them so firm; and it is hopeless to expect the same appearance in a walk which, perhaps, does not number more than twenty pedestrians along it per day; frequent rolling may do much to consolidate it, but it can hardly be expected to compete with the other. There are also different kinds of gravel; the best for ordinary purposes in private places being somewhat porous, and consequently liable to loosen a little in dry weather. This must not be complained of too much, as the opposite kind, which sets almost as hard as cement in summer, is also impervious to rain, and consequently objectionable. A medium kind is of course best. The difference in the two kinds named, consists in the fine substance which intermixes with the stony particles; if this is a sharp sand the gravel is of course porous, and becomes firmest in wet weather. If it is a loamy clay, which very often prevails when the gravel is rounded like eggs and marbles, then it sets very hard in dry weather; but when small portions are broken-up it sets badly again, until the mass is also broken. The loamy substance also sticks to the feet after rain, until, by continued rains, it becomes consolidated between the stones, and the latter stick up like a miniature pavement, the sole of the pedestrian only bearing on the top of the stones, much the same as in the pebble-paved walks previously alluded to. It, however, seldom happens that there is any choice in gravel, circumstances determining beyond a question the kind to be used. The best, therefore, must be made of the kind at hand; if it is too stony, part of the stones may be taken out; if too fine, some of the sand or fine loam may be sifted and removed. The quantity of really good gravel required in making a walk is not so large as might be expected; the bottom and even part of the top may be of an inferior kind, the surface only being good. Every one knows the colour in general estimation, but there are other colours as well. Local circumstances, however, always determine this. A kind of spar gravel I have seen in North

Staffordshire and also in Derbyshire is very good; and perhaps the kind that is the least of all agreeable, especially to the feet, is that found on the seashore. Where this kind is used it ought not to be larger than beans or peas; and the large kind sets badly for carriage roads and similar purposes, although often used for such, there being so little adhesion in the round marble and egg-shaped pebbles which constitute the bulk of seashore stones or gravels.

ASHES OF VARIOUS KINDS FOR WALKS.—There is great diversity in these. A sort of red furnace ash or cinder makes perhaps a better walk than any kind of gravel, worms and weeds both disliking it. Unfortunately, it is not to be had excepting in a few places; but the refuse ash and clinkers of many factory works may be advantageously used for walks, the great advantage being their porosity, and at the same time they often set well, and wear as smooth as the best substance that can be had. The colour may be too sombre for some places, but for secondary walks they are invaluable; and, as before stated, worms seldom meddle with this description of walk. Sometimes the pernicious substances with which such ashes are mixed are distasteful to weeds: thus the ash from soda, copperas, different alkalies, and other chemical substances manufactured in certain places are more or less poisonous to vegetation, though rarely hurtful to the roots of trees or shrubs that may be underneath.

SUBSTANCES USED FOR SURFACING WALKS.—Where the material a walk is mostly composed of is not of an agreeable colour or quality, it is not unusual to give it a top-dressing with something better. In some districts, a fine white spar gravel is to be had by washing and sifting, and in others white shells from the seacoast are used for this purpose; the latter, when resting on a foundation of brown gravel or sand, presenting a sort of creamy grey colour, clean and agreeable-looking after rain, and easy to walk upon. The spar gravel is also equally pretty, and many other substances are likewise used at times, more especially to give colour, in some gardens, to the polychrome features recently become so fashionable, as brickdust or chippings, both buff and red, small coals, and broken-up glass or chinaware. The many substances which may be worked into a walk are so numerous, that it can hardly be expected of any one individual to mention them; but they will readily present themselves to those who notice what is going on around them.—J. ROBSON.

(To be continued.)

THE GOOD-GRACIOUS PANSY.

I BEG space for a short, but not unimportant, remonstrance. In page 26, describing Mr. Beaton's Double Pansy, which seems likely to have a great demand, you give its name as "Good-Gracious," by which you "trust it will become generally known." Indeed, I trust it will not. To some, nay, I hope to very many, of your readers, such an appellation jars painfully upon the moral sense, as something excessively near a transgression of the third commandment of God's holy law. Is not this the appellation of the blessed God? What is the essential difference between saying, "Good gracious!" and "Good God!"? Are not both equally the common invocations heard from the lips of the profane? Let us not be repelled from the love of flowers by profanity.

It does not appear that Mr. Beaton himself has invented this unseemly name; and from what I judge of his character from his writings, I hope he will repudiate it, and protest against it.

Expressing what I am sure will be the thought of hundreds, I will not conceal my responsibility under a pseudonym, but subscribe myself—P. H. GOSSE, *Torquay*.

[We coincide with our correspondent's dislike of the name, and have to explain that when the words "by which appellation we trust it will become generally known" were written, we had received the Pansy under the name of "Princess Alexandra;" and that just as the Journal of last Tuesday was going to press, and after the sheets had passed from our hands, Messrs. Carter and Co. sent requesting that the name might be changed. Messrs. Carter are responsible for the change. Neither the Editors nor Mr. Beaton knew of the alteration until subsequently.—EDS. J. OF H.]

TORTOISES BREEDING IN ENGLAND.

A FEMALE land tortoise was brought from the West Indies and was given to the mother of Mrs. Williams upwards of fifty years ago, it was then about the size of a watch.

It has been in the garden at Tregulow near Scorrier, Cornwall, about thirty-two years.

Four years ago, another was obtained, which turned out to be a male. They were allowed to roam in the garden at their will.

In 1860 some eggs were found, but from insufficient heat they were not hatched.

About the 25th July last, the gardener on passing a south border observed the female tortoise making a pit with her hind legs in a very peculiar manner. On watching her he found she had made a hole some 4 inches deep, quite flat at the bottom. On returning in about five minutes, he found she had deposited six eggs, and was in the act of covering them with earth. He immediately removed them in a flower-pot stand, about 2 inches deep, filled with white sand, to a pine-pit, and placed them on

a tan bed. On the 16th of October following, he observed two of the eggs had been hatched, and on looking around, he found, much to his astonishment, two young live tortoises.

The eggs are about the size and appearance of those of a pigeon.

The young ones are kept in a pine-pit in a wooden box, with some earth and moss, under which they nestle, they are fond of lettuces and strawberries, but do not eat much; they appear quite well and lively, moving about briskly, and are now (January 10th) a little larger than a half-crown.

The eggs were not disturbed while in the pine-pit, the temperature of which, during the time they were there, was from 85° to 90° by day, and from 65° to 70° at night.

The female measures 12 inches long, by 12½ inches wide; the male 8 inches long, by 8½ inches wide, each over the back.

ORNAMENTAL PLANTS.

1. *ROUPELLIA GRATA* (Agreeable Roupellia).—This beautiful stove climber is an evergreen. It belongs to the natural order Apocynaceæ, and to Pentandria Monogynia of the Linnean

system. It is a native of Sierra Leone, and produces in May its white fragrant flowers in cymes at the ends of the side shoots. It is known as the Cream Fruit of tropical Africa.

2. *ESCALLONIA MACRANTHA* (Large-flowered Escallonia).—This handsome hardy evergreen shrub is of a genus which gives a name to the natural order Escalloniaceæ, and it also belongs to Pentandria Monogynia of Linnæus. It is a native of the cold districts of Chili. Its terminal corymbs of purplish-crimson tubular flowers open in June.

3. *DIPLADENIA UROPHYLLA* (Tail-leaved Dipladenia).—A

stove evergreen shrub of the natural order Apocynaceæ, and Pentandria Monogynia of Linnæus. It is a native of the Organ Mountains in Brazil. Its leaves terminate in a long point, whence it obtained its specific name. In June its racemes of flowers open; they are long, funnel-shaped, creamy outside, yellow within, spreading into a five-lobed salmon-coloured limb.

PROTECTION FOR HOTBED FRAMES.

A FEW months ago I saw advertised, "machines for making straw matting," to protect frames, &c. As much has lately been said in *THE JOURNAL OF HORTICULTURE* on this subject, I should be glad to know whether any of your subscribers have tried it. I should say it would answer. My own plan is this—Two Russian mats covered on one side with waterproof calico, and stitched round the edges with twine; these are made the size of the glasses, and a light wooden shutter covers the whole. The shutter keeps all dry—the great point. I find this answers perfectly on a cold pit.—A. R., *Bromley*.

[We have not tried the patent mode. About a year ago Mr. Fish described a homely machine for making strong straw matting; but in wet weather the mats were very heavy to move. We prefer them fastened to frames the size of the sashes. The mode of making them was also described. If the expense of covering them with a waterproofed material was gone to, these straw covers would be very good. We do not see the use of waterproofed calico on the mats, and light wooden covers too. That would be like eating bread, butter, and cheese in slices, all of equal thickness, at the same time. We do not think there is anything equal to wooden shutters, with straw or Russian mats, or any warm material below. A thin, flexible, waterproof covering to keep all dry, would be valuable, especially when hands are scarce, as it takes two to move most kinds of frame-covers.]

ORNAMENTAL FLOWER-STANDS.

So much attention has been devoted to decorative art, that it is by no means surprising to find it prominent in those departments of social economy with which the culture or enjoyment of flowers is more especially connected. Flowers, too, and those of the choicest kinds, of all hues, and of the most delicate perfumes, are in these days brought so far within reach of all who find any enjoyment in the refinements and luxuries of civilised life, that not only in the garden and greenhouse, but in the parlour and boudoir, they become almost necessary ornaments.

The accompanying figures show some of the ways in which art and nature, under the form of vases and flowers may be brought into intimate association in the sphere just alluded to. They are from designs by A. Aglio, Esq., jun., and are intended to be constructed in terra cotta, or zinc, on a large scale, for terrace gardens, halls, and similar situations, where they are to be filled with ornamental plants in the growing state; or they may be made in porcelain, or any fine material, as stands for cut flowers, or smaller plants suitable for in-door-decoration.

The sketch above is of a vase intended chiefly for the table or boudoir, and to be constructed of coloured glass, porcelain, or the finer earthenwares, either plain or with the ornamentation coloured. When filled with cut flowers, these should be arranged amongst fine green moss, kept continually damp, and may or may not be covered by a bell-glass. In addition to the central stand, this vase has the three supporters continued upwards into a kind of cornucopia to hold smaller flowers, and they may be appropriated each to hold a small plant of some elegant Fern. For these purposes, the size may range from 18 inches to 2 feet in diameter. This design may be made of larger size, 3 to 4 feet in diameter, and of zinc or terra cotta, for out-door use, where it may be employed with much appropriateness in detached

terrace gardens, or in situations where vases of summer-flowering plants are required.

The larger design is intended for the double purpose of cultivating a few very choice Ferns in the upright vase, covered by the bell-glass, whilst the stand in which it is placed is to be kept

filled with cut flowers. The supporting figures hold cornucopias which are intended to take some very choice flower, such as a fine Moss Rose, a Camellia, a fine sprig of Fuchsia, &c. The lower stand may, if preferred, be planted with Lycopodiums—*L. denticulatum* being preferable for this purpose. The diameter of the stand may be conveniently from 2½ to 3 feet, and the diameter of the vase 1 foot; the height about 3 feet. It may be made of glass, porcelain, terra cotta, or metal; or the figures alone may be of metal. Colour may be appropriated for the figures and ornamentation.

When vases of this kind are employed for the growth of living plants, the first consideration is proper drainage; there must be no stagnant water. This being the case it would be preferable to use the centre vase for growing plants, and allow this to drain into the lower one, which could be employed for cut flowers. The next point is soil: this should be turfy peat, with plenty of sand intermixed, the mass resting on a thick layer of broken crocks for drainage. Then the plants, if in a living-room, must be constantly covered with a bell-glass; and enough water must be given to keep the soil and atmosphere moist, but not saturated.—(*Gardeners' Magazine of Botany*.)

DISTRESSED WORKINGMEN BOTANISTS OF LANCASHIRE.

THE many kind donations I have received from time to time from your readers has enabled me to cheer many hearts here, and some who were accustomed in times past to take a three or four days trip into Derbyshire, or other parts favourable to Mosses, when the weather permitted, at a Christmas time, have not been denied a part of their usual hunt after Mosses this year, thanks to the liberality of the readers of *THE JOURNAL OF HORTICULTURE*.

There is a slight improvement in trade. Roger Schofield has had from one to two and a half days per week of work for the past four weeks, and John Whitehead has gone on five days per week last Monday; but will have hard work and little pay until a better quality of cotton can be had. Two others have a little more work, but the rest are as they have been for a long time.

I have had to neglect several correspondents this last week or ten days through indisposition, but hope to answer all in a few days. I have received from Miss Baling, 10s. for wet Mosses; from Mrs. Lewis D. Wigan, Rock House, Maidstone, £1 11s. 6d., for Ferns, green and dried; from a Working Gardener, 2s. 6d. (monthly); from William Moulton, Esq., £1, for dried plants; from Lady D. Nevill, £1.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

P.S.—A Mother, from Ipswich, has sent every week since I last noticed it, 2s. 6d. each to Whitehead and R. Schofield.—J. H.

WORK FOR THE WEEK.

KITCHEN GARDEN.

PROCEED with digging, trenching, &c., whenever spare ground occurs and time permits. If some of this ground should require digging a second time previous to cropping, so much the better; it will amply repay the labour. *Broccoli*, a little *Early Cape* sown in a box and placed in heat, will be serviceable for early summer use if there be a deficiency of *Cauliflower*. *Cabbage*, sow a little in a box to be excited by heat, if there is a scarcity of autumn-sown plants. *Atkins' Matchless* is a good sort for the purpose. *Celery*, sow also for early summer use, for soups, &c. It cannot be depended upon as a permanent crop, as it will generally soon run to seed. *Lettuce*, sow in boxes. Give air to those in frames when the weather will permit. *Onions*, sow seed of the Spanish in boxes for planting-out in the spring. *Potatoes*, the *Early Frame* or *Ashleaved Kidney* may be planted in the beds on which *Asparagus* has been forced, or new beds may be made with a large portion of leaves mixed with the dung. Sow *Early Frame Radish* in the same bed, to come off before the *Potatoes* are far advanced in growth. *Tomatoes*, sow some seed immediately, to obtain strong plants fit for turning-out in May.

FLOWER GARDEN.

Where any of the beds in the flower garden require the soil to be renewed, frosty mornings offer an opportunity of doing the work cleanly and expeditiously. Prepare for planting hardy shrubs. If the soil is not suitable for the kinds intended to be planted, replace it with better soil, as much is gained by preparing well at first. Prune hardy climbers during this favourable weather, nailing and tying as you proceed. Relay Box-edgings. Level turf on lawns, adding fresh where it is wanted. Clean walks, turning the gravel where necessary. In March, a thin coat of fresh gravel might be laid on, which would look well during the summer and may be kept clean without much labour.

FRUIT GARDEN.

The late heavy rains have been favourable for newly-planted trees, by washing down the finer particles of soil from the surface among the fibres. In some cases, however, openings may have been formed by the same means, which would prove injurious if not closed-in by working the surface with the spade or hoe; for although the soil may be pressed close to the roots, as it ought to be in planting, yet, in the case of trees with large roots, a settling from heavy rains will cause vacuities near the stem, whilst round the latter an opening is frequently occasioned by the motion of the tree by winds. If water lodge in this it is bad for the tree. Some recommend postponing the pruning of *Peaches* and *Apricots* till late in the spring, or, rather, till the period when severe frosts are not likely to occur; but by late-pruning the force of vegetation is very much diminished. The French only recommend it for trees which are over-luxuriant. When pruning *Gooseberries* and *Currants*, let the centre of the bushes be kept free and open, and cut-out all branches that cross one another, leaving the leading shoots about 9 inches apart, and topping at a bud inclining to the open space. All lateral twigs not required to form branches to be spurred-in to a few eyes. The fruit is borne on short natural spurs, or on clusters of buds formed on the old wood, and also on young shoots, which should be shortened to one-third of their length. Old worn-out branches to be cut-back to a well-placed shoot.

STOVE.

Examine the various tubers and bulbs that are dormant, and see that they are in a proper condition, and not suffering from mouldiness. Do not excite the plants here at present, wait for longer days and more light.

GREENHOUSE AND CONSERVATORY.

The continued damp atmosphere which has prevailed for some time, especially about London, has caused great destruction amongst many softwooded plants. They should be carefully examined individually, and every infected leaf or branch removed. Slight fires to be occasionally applied; but this should be done carefully and judiciously. The injury greenhouse plants may frequently suffer from too much heat, is more than they would suffer from a few degrees of frost when in a dormant state. When regulating the plants, it will be well to wash the foliage of *Oranges*, *Camellias*, and other smooth-leaved plants with a sponge and clean water, and the dust may be removed from *Pelargoniums*, and other woolly-leaved plants, by brushing them lightly with a soft brush. After the plants are cleaned the pots should be washed, and the surface in each replaced with fresh soil, and if the plants require it they should be neatly tied to fresh stakes.

PITS AND FRAMES.

Where there is the advantage of a little fire heat, a sowing of *Ten-week* and *Intermediate Stocks* may be made. If unfavourable weather for out-door work should set in, the most forward of the *Verbenas*, &c., in stock-pots may be potted-off, to be then supplied with a little heat until they make fresh roots.

W. KEANE.

DOINGS OF THE LAST WEEK.

RIGHT or wrong, we are beginning to think that we shall drift behind with all out-door work, from so much and continuous wet with scarcely a ray of sun to cheer us. When fair abovehead there never could be a better winter for turfing lawns and planting fruit, forest, and ornamental trees. In stiff soils digging and trenching have often been out of the question. It is often sound economy to let such ground stand until drier weather, as when turned up so wet it scarcely ever pulverises kindly. On Monday morning, the 12th inst., we had the sharpest frost of the season—and unexpectedly, too, as at eleven the previous night it was quite cloudy and inclined to drizzle, with the wind, however, veering to north and east. Some plants in pits were just slightly touched, as air had been left on some of them; but syringing them with cold water, shutting-up close, and keeping shaded all day, there being sunshine in the forenoon, has now made the plants all right, with no marks of the frost on them. On that morning until mid-day all strength was directed to wheeling dung and rotten leaves on borders and flower-beds at liberty. For the latter purpose at this season, we prefer the beds to be rough-ridged at first, and then the slight manuring spread roughly over them. The exposure to the air and frost sweetens it without abstracting in cold weather much of its nourishing properties, these being washed-in by the rains; and from its sweet and pulverised condition it mixes better with the soil in future turnings as the days lengthen.

On Monday afternoon it commenced raining, and it continued to rain heavily without intermission for about twenty-four hours. It is these sudden changes that make it so important for us to be constantly on the watch, and to regulate our work and doings accordingly. From the force of the wind much wet was driven into our late vinery, and did no good to the late *Grapes*. From what cause we know not, a good deal of putty this winter has got as crumbly as bread-crumbs, and of course can offer no resistance to wet; and the puzzle is that one sash-bar will be thus affected from top to bottom, and the next one to it be as firm and smooth as possible. Sometimes a whole sash will be thus affected, and the sash next to it as sound as need be, and, so far as we know, all were glazed with the same putty, and used in every respect exactly alike. Can any reader throw any light on the subject? Several painters and glaziers confess themselves to be nonplussed.

KITCHEN GARDEN.

Examined vegetables as last week. Prepared materials for hotbeds, for *Carrots*, *Potatoes*, &c. Gave plenty of air to *Potatoes* in pots, *Peas* in pots, &c.; took-up more *Sea-kale* and *Rhubarb*; beat and trampled-down a fresh piece of *Mushroom-bed*; potted *Cucumbers* into small pots in a dung-and-leaf frame; and prepared ground for *Shallots* and *Garlic*, as it is as well to plant before growth commences much. We prefer autumn-planting of the whole; but in stiff soils they do as well in spring, fastening the little bits in drills half an inch deep, and then covering-up with light soil and lime which keep the birds and worms from unsettling them.

FRUIT GARDEN.

Much the same as last week. Put Strawberries on an empty shelf in the Peach-house and back of narrow Vine-pit. Syringed Vines in a sunny day as the 14th.

Looked over *fruit-room* in wet afternoons, and put some Vine-pots into a leaf-bed to bring them on gradually; watered the Vine cuttings in pots. Put a few warm leaves close to the wall of Peach-house to keep the roots there comfortable; and laid a layer of straw neatly along the back of a narrow pit, used for Vines and other early things. This wall is from 4 to 5 feet in height at back above the ground. The straw is placed on neatly about an inch thick, and three strings along fasten it securely. In cold weather the straw covering makes a great difference in the heat. When the outside of the straw was all covered with hoar frost the wall inside of it was as comfortable as a warming-pan. The wall is 9 inches thick, and rather old and worn out. In a hollow wall or near a coalpit such keeping-in of heat need not be resorted to. The last straw covering of the walls lasted three years, and half a load of straw would do more than 200 feet in length of such a wall. For cold pits made of brick it is the neatest and best mode for making them secure in winter. We recollect a pit of nice plants being securely protected as respects the glass, but the frost went through the brick walls and did all the mischief.

Talking of heat brings me in mind of a chance expression we used some time ago as to a return being made in large places to the saddleback boilers, which I see has brought out two correspondents in praise of Mr. Clarke's tubular boiler. Though we have done little with the working of such boilers, yet in describing Mr. Weeks' system of heating we then professed so far our adherence to it. The whole of the rest of these tubular boilers are borrowed or adapted from Mr. Weeks' plan; but if other boilers are well set they will also do their work well, and if not convinced they would do so, they would not adopt them at Trentham, and in such splendid new gardens as those at Welbeck. Give only a dash of zeal and enthusiasm, and a gardener will make a common boiler do wonders. For ourselves, however, on various accounts, we have a hankering after the upright tubular boilers, though we have heard of considerable bracking and flying among them.

ORNAMENTAL DEPARTMENT.

Looked over the plants in conservatory, and gave more water to Camellias swelling their buds, to Cinerarias, &c. All forced plants should go at first to the closest and warmest end. Chinese Azaleas, after the middle of January, need but little heat to start them into bloom. All plants from bottom heat, as Hyacinths, Lily of the Valley, Musk, &c., should be raised out of the plunging material a few days before being moved. All such plants should be as carefully guarded against sudden changes as any pet in the animal world on which we set a high value. Give plenty of air to Heaths and Epacris, and other hardwooded plants; but when the temperature outside is near freezing, give little or no front air to beat on the plants. A few Gardenias may be put in a sweet hotbed, and air given at first. Succession bulbs may also be started. Little is gained by forcing Violets; but a little bottom heat, and plenty of air in suitable weather, will cause them to come finer and stronger. All runners should be removed from the Neapolitans, which are as sweet as any still. For cool houses and entrance halls, the *Aspidistra nudiflorum* would be very showy at this season, especially if grown with a stout stem and a drooping head. The wet and the frost injure the flowers outside, but kept from wet, the plant might look like an umbrella of green and gold. It has no scent, however.

PITS AND FRAMES.

Found that the mice had penetrated into a frame of bedding *Calceolarias*, and nipped-off the tops of one kind entirely—Victory, a small dark sort. Poison and traps must be laid for them. These cuttings were put-in in November after the first frost, and have just rooted too well; not one, we believe, has nipped, and all are quite healthy. We shall not know where to find room for them. But for the frost coming, it would be quite time enough to put-in these cuttings in December, as the sooner they are put-in and the sooner they root, when planted so thickly the sooner do they demand thinning and moving in spring. A few plants were covered all day on the 12th, as they were not protected the previous night. Having made a little room, we have commenced taking-off some hundreds of cuttings of variegated *Alyssum*, variegated *Geraniums*, *Crystal Palace* *Nastur-*

tiums, &c., as at this season, with a little bottom heat, they strike quickly and need no shading. Whilst the sun is so low, we prefer, in a sunny forenoon, giving a slight syringe overhead in preference to shading or watering. Who is to let out the pretty new *Lobelia*?—R. F.

TRADE CATALOGUES RECEIVED.

Sutton & Sons, Reading.—*Spring Catalogue and Amateur's Guide for 1863, Containing Selections of Kitchen-Garden Seeds and Roots, Flower Seeds and Plants, and Agricultural Seeds, together with Cultural Instructions.*

W. Steward & Co., 18, Drake Street, Plymouth.—*Price Current of Garden, Farm, and Flower Seeds.* 1863.

James Lothian, Campbeltown.—*List of Dutch Flower Roots.* Autumn, 1862.

B. S. Williams, Paradise Nursery, Holloway, London.—*Catalogue of Flower, Vegetable, and Agricultural Seeds, Bulbs, and Roots.* 1863.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

CELERY (*County of Durham*).—We do not think that the variety grown had any connection with the "bolting" last autumn. The same occurred very generally, and to every variety. The cause we believe to have been a check to the growth of the young plants, caused by ungenial weather at pricking-out time.

SIZE OF FLOWER-POT (*Country Secretary*).—We know of no rule requiring the diameter of a pot to be measured an inch below the rim. We think it ought to be measured close to the rim. All such measurements are taken inside. An eight-inch pot ought to be 8 inches diameter next to and within the rim, and 8 inches deep perpendicularly from a stick laid across the rim to the bottom of the pot inside. A small fraction of an inch, provided not exceeding an eighth of an inch more, in any such measurements ought not to disqualify.

GARDENER'S RESIDENCE (*W. A. B.*).—There is no doubt that it would be more fitting for the gardener, if married, rather than the married groom, to live in the garden-cottage; but we are quite sure that public journalists have no right to interfere with such arrangements. The gardener must plead his own cause with his mistresses.

WHITE BRAMBLE (*Rubus Biflorus*).—Any of the large London nurserymen who advertise in our columns could supply you with it.

SCARLET GERANIUMS IN POTS (*L. C.*).—There is no particular treatment required now, nor until next May, for Scarlet Geraniums, nothing more than to keep the frost from them and to see they do not want for water, and that they have no more water than will just keep them alive. The pots ought to be more or less dry all the spring, but not so dry as to cause a leaf to flag.

FERNS IN CRINOLINE POTS (*H. B.*).—As far as we can judge, in the absence of actual experience, we should say decidedly that the cocoa-nut refuse dust would be more suitable for Ferns grown in crinoline pots than for those in common pots. Let us say a crinoline pot is another name for a sieve-like pot, or pot-basket of wirework, with meshes of greater or less diameter all over it. Then say, use such pots of double or three times the size of clay pots for Ferns; line them with thin flakes of the surface of peat soil, and cram them as tightly as you can press it with the dust from the cocoa-nut fibre mills, and if the Ferns do not flourish in crinoline pots in that way much better, and at half the expense, of attendance, than they ever did before, we should be very much surprised. We have only just learned that the Ferns at the great International Exhibition, which Ferns were only bought for the purpose at the Kingston Nursery the week before the opening of the Exhibition, were then shaken out of the peat and planted in the pure cocoa-nut fibre dust; and the plants were only watered four times the whole time they were on exhibition, and then only by men who never before watered Ferns and only a very few common plants.

GOLD AND SILVER FERNS (*A Subscriber*).—The chances are against your Gold and Silver Ferns doing any good after having lost their fronds, from bad packing and too much cold, no doubt. 50° is the lowest temperature for them in winter, and 55° to 60° should now be the warmth for your leafless ones, and keep them a little moist at the roots; do not give them up before the middle of May. *Gymnogramma* is their botanical first name, and the different kinds have various second names. This is the worst time to give lists of *Fuchsias* and *Pelargoniums*, as better sorts will be out immediately in the spring catalogues.

HARDY AQUATICS (W. Beard).—We cannot say where you can purchase these; but nurserymen who have not a piece of water generally procure them from some place where they are plentiful. There are usually plenty to be had from most ornamental waters, and we have seen the most of them growing in small rivers and marshy grounds round London. We have no doubt this notice or an advertisement will bring you news of them. To your *Galla palustris*, *Hottonia palustris*, *Butomus umbellatus*, and *Nymphaea alba* we would add the large-flowering gorgeous *Nuphar lutea*, *Stratiotes aloides*, *Menyanthes trifoliata*, and *Aponogeton distachyon*. This last-named had better be planted in pots, sunk near the margin, and in severe winters the pots could be raised and set in a tub of water in a close shed or greenhouse.

CENTAUREA CANDIDISSIMA (A Subscriber).—*Centaurea candidissima* is not better than *Cerastium tomentosum* for some edgings, and it is much better for some others than any other plant in cultivation. All depends upon the plants in the bed to be edged.

LIQUID MANURE FOR VINES (An Amateur).—If your Vines are in-doors, and the roots dry, you may use your water-closet sewage, much diluted and heated to from 80° to 100°, before starting the Vines. If the roots are out of doors, the roots most likely will be wet enough, and water is not likely to be required until the ground becomes dry and warm—say from June to September. We would even then, however, use such material with great care. It is almost sure to be too strong, unless much water is added. We once knew fine Vines completely spoiled by using the liquid strong and in a fresh state.

BONE DUST FOR PELARGONIUMS (New Year).—Give your strong Geraniums no manure water or top-dressing until the flower-buds are formed and forming. Then, instead of watering, you might put a quarter of an ounce on the surface in each pot, and give as much more again in ten days. Mixed with water, you might use about three ounces to four gallons of water, mixing it up the day before. See answers to correspondents last week. We like to vary the stimulus just on the principle that a person will thrive better on beef and mutton alternately than on either continuously.

CAMELLIA FLOWERS IMPERFECTLY OPENING (S. D. G., Ireland).—Your *Camellia Hawkeri*, which both last year and this formed fine large buds, of which a few of the outer petals opened but the centre continued a hard ball and finally fell off, requires the centre of the ball of earth to be wet enough and its drainage perfect. In such dull weather, of which we have had so much, air would be advisable, even though a brisk fire should be made in the morning and allowed to burn out, using none at night unless frosty.

APPLE TREES MOSSY AND BRANCHES DYING (G. C.).—If your trees are not too far gone they may be, to a certain extent, renovated by a slight, not a heavy pruning, and by lime-washing the stems and branches as far as you can, coating them thickly with the lime. On a fine, mild, and slightly damp morning in April let a man with a ladder go round and throw some quicklime all amongst the tops. A great part of this will, of course, come to the ground; but it will do no harm there, and what falls amongst the mossy-covered branches will stick to them, and in a great measure destroy the moss. A damp, calm day is best for this work. Much good will also be done by manuring the ground; and, if it is in tillage, do not by any means dig it deep. If these remedies fail, it would be better to destroy the trees and plant again elsewhere. Cutting-down and severe pruning rarely answer for above three or four years, unless the trees are young and vigorous, in which case they seldom want this, excepting to change the kinds.

VENTILATION OF STOVE AND GREENHOUSE (A Lady).—You will see an article in our next Number on this subject, but we may here say that during the dull months 55° may be regarded as the minimum for a plant-stove, and 38° for a greenhouse. You may, however, give air freely to the latter; but the former will require but little until brighter weather set in. The sand in your stove may be kept damp when plants are growing, but when they are at rest keep it dry. Your further inquiries will be met in the article above alluded to.

PLANTING BELLADONNA LILY (A. S.).—The depth for planting these was stated to be 6 inches in the article you allude to. Mr. Beaton has always said that all bulbs which remain in pots from year to year are more safe if buried as low as the neck of the bulb; and when they are not so potted many of them perish from the damp of our hothouses and open-air climate penetrating between the coats of the bulbs when they are at rest. The treatment of *Eucharis amazonica* has been given in every volume of this Journal for the last seven years. The treatment for 1863 is this: To have it always and in all places under-potted—that is, to have the bulbs in smaller pots than Lily bulbs of the same size; to use nothing this season but the best loam and about one-sixth of the quantity of sand; to give it stove heat from first to last, and, better still, to plunge in a hotbed of 80° bottom heat and 70° of top heat from the middle of February to the end of May; and to keep it as constantly watered as a pot *Pelargonium* every day in the year.

PANCERATIUM MEXICANUM (Idem).—You have given the key to your gay-deceiver bulb. You say this *Pancratiium* is dreadfully subject to thrips. There never was a more direct libel, for there is no plant the thrips dislike worse than a *Pancratiium*. Your bulb from Mexico is not a *Pancratiium* nor a stove bulb at all, and you did not give it one-quarter of the quantity of water it requires in the heat of a *Geranium*-house. Your *Pancratiium* which flowered two months ago was a genuine *Hymenocallis*. Mexico is full of these, and from almost hardy to stove kinds; and the whole of the *Hymenocallides* of the American continent require saucers of water under the pots from May to November, and the saucers to be kept full of water the whole time. From the want of water, and from too much heat probably, the juices of your bulb were made so sweet that even the thrips could not resist the temptation of sucking the leaves. Although the bulb is so much like a *Pancratiium* that no man could tell that it was not a *Pancratiium* while it was in flower, no botanist can tell a *Pancratiium* from a *Hymenocallis* without seeing the seeds. But test your bulb be not so hardy as would seem to be the case, go through with it one more season in water in the stove, but nearer to where air is admitted; and if you see one thrips on it, remove it immediately to a greenhouse.

COCOA-NUT FIBRE DUST (A. H.).—One of the best covers over an open tank to let up vapour, and to keep out the dust of the cocoa-nut fibre, is the bristly refuse of the fibre of the nut, or the refuse of the mat and brush makers laid upon a floor of galvanised iron net.

MAGPIE PANSY (Idem).—Mr. Salter, of the Versailles Nursery, who raised that beautiful flower, is the most likely person about London to have it on sale. Mr. Beaton said in the article you allude to that he shared it with Mr. Salter.

MARIGOLD AT KENSINGTON (Lex).—Marigolds have florets, not petals. That you saw at Kensington has the best name; it is called *Pot Marigold* in all the seed-shops, and is one of the best town flowers we have.

ZINNIA FLOWERS (Idem).—The diameter of double Zinnias, like the diameter of Dahlias and all such flowers, varies very considerably in different varieties; we have seen them from 1 to 3 inches across. All depends upon the variety and on the way the plants are treated.

STOVE WITHOUT FLUE.—“I have always understood that to be in any confined place where coke was burning in a stove or other apparatus, without a flue or pipe to take the smoke and sulphur away, is injurious to the health of those who inhale the fumes of it for any length of time. I should be much obliged by your opinion on the subject.”—JOHN JONES, *Ryde Gardens*.

[Such fumes are very prejudicial to health. A stove without a flue-pipe is quite as bad as a brazier burning charcoal, which has caused so many deaths to those sleeping in a room where one was placed. The fumes cause headache, oppression of the chest, fainting, and palpitation of the heart.—EDS.]

APRICOTS FAILING IN ORCHARD-HOUSE (A Subscriber).—Mr. Rivers' plan of treating the tree as an out-door one is more likely to insure fruit than when it is in-doors; but in that case what is the use of the orchard-house? Apricots have been tried under glass upwards of thirty years ago, and failed then. It is possible that by letting them have almost a superabundance of air they may set better, and possibly they may swell and do well under glass; but we have much doubt of it. As a fruit tree the Apricot is more hardy than most others, and requires a cooler and stiffer soil than the Peach; and if your trees in pots do not furnish fruit this season, we would say plant them out as bushes in the open ground, and report the result. If your situation be a dry one, we fear your trees will not be fruitful against a south wall; or even when they do bear, the fruit will not unlikely ripen and decay on one side before the other side is ripe at all. An east or west aspect is better than the south for the Apricot. We are, however, promised an article on this fruit by one of the contributors to our Journal, which will doubtless contain some useful matter bearing on your case. In the meantime, let your gardener prune and regulate your wall trees in the proper way, and if very cold weather occur at the time they are in blossom, protect them only at night. A close uniform protection of netting, or anything that way, though useful and beneficial to the Peach, is not required by the Apricot, which, with the exception of the Plum, is perhaps the hardiest fruit-blossom we have.—J. R.

OLD HOTBED DUNG (M. H.).—This, and that in the bin you mention, although all exposed for a length of time to the weather, will still be so abounding in fertilising components as to be very useful if applied to your Rose trees.

SUMMER-PRUNING DWARF PYRAMID APPLE TREES (W. J.).—Your trees, which you say were pruned in summer and have since made shoots 10 inches long, have evidently been pruned too soon. It is better not to prune either wall, espalier, or any other trained Apple tree until the young wood begins to harden at the base—say for a couple of joints or so; then there is less fear of its exhausting itself by shooting again. This you should bear in mind another year; but, in the present season, you must prune-off the half-matured shoots that have been made since the summer-pruning, leaving, however, a little at the base if the tree should want enlarging. The top will also want shortening accordingly.

WORN-OUT QUICKSET HEDGE (Alpha).—You are perfectly right in destroying the old worn-out hedge, and replacing the soil it has been growing in for other mould, as no good results from planting the Quick plants in the same soil again. Your mode of planting two rows of Quicksets a little distance apart, and a row of Privet between them, is very good for making a good hedge; but as the Privet grows much faster than the other, we would put in cuttings of this instead of rooted plants, thus enabling the Quickset to have a start at least equal with the Privet. If the two rows of Quicksets were a foot apart, carefully planted on good fresh soil that had either been in tillage or taken from a meadow field, and cuttings of Privet a foot or 15 inches long thrust in between them, say 6 inches apart, you will likely have a good hedge in a short time. We would prefer this to Hornbeam or Beach, which are better adapted for shelter than for turning cattle, retaining their old leaves most part of the winter.

NAMES OF FRUITS (H. B.).—*Apples*.—1, Striped Russet; 2, Lewis's Incomparable; 3, Oxnead Pearmain. The Pear is Vicar of Winkfield.

NAMES OF PLANTS (A Reader).—1, *Coronilla glauca*; 2, *Genista racemosa*; 3, *Erica hiemalis*; 4, *Hardenbergia monophylla*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DORKINGS.

WE cannot resist the temptation of writing a little on Dorkings. We have often done so before, but it is long since, and the question has re-appeared on the surface. Like many other similar matters, essentials are ignored, and trifles are placed in the front rank. Two points have been greatly and most improperly insisted upon as being of first-rate importance—combs and plumage. Both are ridiculous as essentials. The comb of a Dorking fowl is quite immaterial, and it always was; but so much was said about the rose or double combs that they are now but seldom seen; they were formerly numerous, and were the largest birds. We were more than glad to see Lady Holmesdale show such good rose combs at the Crystal Palace. The most ridiculous attempt was to endeavour to make Dorkings birds of plumage, and it was endeavoured to lay down the rule

that unless the tail and breast were perfectly black the bird was not true. Now, nothing could be more mistaken, and it was decided at the time not only that the points mentioned were not essential, but that they had nothing to do with the purity or otherwise. Yet a correspondent writes, he always thought a prize Dorking should have a black breast; whereas he had seen one with white spots or speckles all over it, and thereon he brings an objection to an award. More recently we hear from a Scotch show that birds of unquestionable merit were disqualified because they were too dark in plumage.

It was to satisfy a longing that could not be legitimately encouraged that Silver-Grey classes were introduced; they were a concession made to those who, like our correspondent, would have Dorkings to be birds of plumage. Here their own ideas were embodied, and Dorkings were judged to colour. Few exhibitors have been satisfied. Nevertheless, the remedy is in their own hands, the points are thoroughly understood, and the black breasts are indispensable; but they are the exception, and even in these special classes numbers of cocks lack them. If other proof were wanting, the statistics of the yards where Dorkings are bred would prove the difficulties attendant on the endeavours to breed them to feather or colour. That which amateurs have successfully tried has been to ally increased size and weight with perfect symmetry. This could never have been one had there been any restrictions of colour. We give our best support and our adhesion to the Silver-Grey classes. Exhibitors send them in sufficient numbers to make separate classes, and they have, therefore, a right to have prizes offered for them; but they will only have done mischief if the amateurs of them endeavour to disturb the rules that have guided our best judges in making their awards in the general classes for many years. Such would be the effect of listening to the complaints that appear in the mild form of thoughts—"I always thought," &c.; "but I find," &c.—and such is the result of awards for colour that discourage many old and good exhibitors. We have no hesitation in repeating, that which we have often before said, and which the institution in many places of the Silver-Grey classes justifies us in repeating, if possible with more confidence, that Dorkings are not birds of colour; that provided they are large and square, have five good claws on each foot, are alike combed throughout the pen, and present no arising disparity of colour; that whether or no the cock has white on his breast or tail, or the hens are a shade darker or a shade lighter, they have all the requisites for successful competition so far as colour and comb are concerned.

SILVER-GREY DORKINGS DEFENDED.

HAVING read the article in your Number of the 9th of December, suggesting doubts as the impolicy of continuing separate classes for Silver-Grey and Coloured Dorkings, as a breeder of Silver-Grey Dorking fowls for almost twenty years I confess I should regret if this suggestion were acted upon.

The Silver-Grey, if properly bred, will never become grey on the breast. It is quite true that where they are thrown out indiscriminate breeding, as is not infrequent, no dependance can be placed upon them; and it is more than probable on the second moult that coloured feathers may and will appear both on the breast, back, and wings. Many such birds are shown in the Silver class as chickens that never can again compete in the same class. This arises from want of sufficient care in the selection of stock birds for crosses. It may be that a bird may have himself all the characteristics of purity of blood, but may probably be an offshoot from an indiscriminate yard.

The Silver-Grey, in my judgment, ought to be a counterpart of the Silver-Duckwing Game. The comb should be large and well defined, deeply and distinctly serrated, not projecting unduly to the beak, and perfectly upright; with breast and tail straw-coloured or whitish; back and hackle with certain well-defined markings on the wings. The hens should be pure silver-grey, free from brown on the wings as may be; the breast salmon colour, not, as is too frequently the case in winning pens, one or sometimes both nearer approaching a brownish-white; the fifth claw separate and distinct, well defined, of sufficient size, and well formed. Any pens not coming up to a defined standard ought to be disqualified if exhibited in this class. If properly bred they will never become, however old, grey on the breast, as I can testify from long experience, for I have hens free, four, and five years old that are as pure and true in their

markings as they were when chickens, and so similar that unless marked the different strains could not be known.

All breeders of Dorkings ought to be obliged to "E. C." for the able article in your Number of the 9th of December relative to the Dorking class at Birmingham, and if his suggestions were carried out as they ought to be, and defined characteristics attended to by the judges, exhibitors would be more careful in their selection of the birds composing a pen. A well-defined fifth claw, so important a feature in a first-class Dorking, seems to be, to a great extent, disregarded, and short, imperfect, and in fact connected or ill-defined claws, seem to be by no means uncommon.

In the Silver-Grey class at Manchester, in Class I, the prizes were awarded to pens having several glaring imperfections. The combs of the cocks were both imperfect. The hens in neither of the pens matched, a hen in one pen having speckled feathers in the breast; in the other pen one hen had a salmon breast, the other a brownish white. One of the rules of most of the great shows is that condition and brilliancy of plumage and well-defined markings, not mere weight, should be the standard for approval. Weight ought certainly not to be disregarded in a Silver Dorking, though it should not be the primary consideration.

Fond as I am of breeding the Dorking I would not accept the best pen of Coloured birds, as all interest with me would cease, mere weight being apparently the only desideratum. The Silver bird, when pure, is in my eye a comely and handsome bird, requiring some judgment to breed; his Coloured namesake is generally a large, shapeless, and fluffy-feathered creature, having nothing but size, produced in many instances by crossing with Cochins, Brahma Pootra, &c.—a step no Silver-Grey breeder dare venture to try.

The numerical preponderance in favour of the Coloured bird at exhibitions arises from the fact that breeders of the Silver birds, from want of care in selecting stock birds for crosses, find themselves at sea, and in despair of righting themselves fall back upon the Coloured birds.

It is quite true that the Silver bird is fast approaching the Coloured even in weight; still they are as distinct in their main features as any of the Game classes, and I venture to hope as a breeder, but only a casual competitor, that the time may be long distant when your suggestion will be carried into effect. I know very many who hold the same opinion.

If this suggestion is worth anything, it goes to undermine the classification of Game fowls; there being as much difference between the Silver and Coloured Dorking as there is between the Black, Brown, or Duckwing Game.

I have endeavoured to show from my own experience that, as regards your remarks in reply to "A BREEDER OF SILVER-GREYS" in yours of the 6th inst., the fowls on which your conclusions were based were not Silver birds proper, but offshoots from indiscriminate breeding.—ANOTHER BREEDER OF SILVER-GREYS.

CORK POULTRY SHOW.

THE poultry exhibited were of various degrees of merit. The *Spanish* were particularly good, Miss Drevar and Mr. Hodder taking prizes with birds that would be regarded as first-class in any show in England. Thirty pens of *Dorkings* were exhibited, and, as was the case last season, were very good. *Cochins*, as a whole, were poor; but Mr. Perry's prize Buff and Mr. Zurhorst's White were remarkable exceptions to this general rule. The *Game* classes showed a great lack of knowledge of this beautiful variety. Duckwing cocks were matched to Black Red hens and *vice versa*, the birds exhibited were destitute of anything like style or beauty, being short-necked, loose-feathered animals that no Game-breeder would endure in his runs. From this sweeping denunciation one or two pens must be exempted. Mr. Perry won in old birds with a good active-looking Black Red that won as a stag last year. But most of the other winners were as lumpy and loose-feathered as Dorkings, and some very nearly as heavy. The Gold and Silver-spangled *Polish* were not so strong as last year, owing to the absence of the birds of Mr. Palmer Williams; but the Gold and Silver winners were well-crested and well-marked pens. Miss Drevar swept the White-crested Black class with better birds than are generally seen at any except the very largest shows. The pen of *Silky Bantams* belonging to Mrs. Hodder were as good as any we have seen lately, the black comb and wattles being well developed, and free from any tinge of redness.

In the "Any other" class, Mr. Perry won first with as good a pen of Crève Coeurs as we have seen for some time.

Turkeys were very good.

Geese were of various kinds, many pens of Chinese being shown; and under the name of Danubian, there were many pens precisely similar to those loose-feathered birds that Mr. Harvey D. Bayly has shown under the name of Sebastopol.

Ducks were large and good.

The *Pigeons* were truly a magnificent show. The class of Black Carriers was of extraordinary merit. The Powters were very good; Mr. Hawkins, of Belfast, brought the birds with which he won at Glasgow last week, and carried off many of the prizes, being closely pressed by Dr. Harvey, who was also very successful. The Short-faced Almonds and Kites were numerous, but not equal to the Powters in merit. Twenty-five pens of Fantails made a feature in the show-room. The winning birds were very good, particularly the Blues and Blacks; Jacobins poor; but Barbs very good, particularly those of Mr. Perrott, Miss Pike, and a cock of Mr. Dowling's. The Sweepstakes for the best young Carrier was won by Mr. Goulding with a splendid young Dun, the bird of Dr. Harvey being of almost equal merit. An "Extra prize," given for the best young Powder and Short-faced Tumbler, was won by Mr. Hawkins with a Blue Powder and Almond cock. The White hen, exhibited by Dr. Harvey for this prize was one of the best birds we have ever seen, very long in the limb and feather; but her chance was damaged by the Kite with which she was associated.

The birds were exhibited in the Halifax pens, and were managed in an admirable manner. No show in the kingdom is conducted with more spirit and energy than the Cork Exhibition: consequently it yearly increases in the number of entries, and in the interest it excites, as testified by the number of visitors.

We understand that many additional prizes and medals will be given at the next annual Exhibition.

We published the list of prizetakers last week.

MR. HUTTON VERSUS MR. MUNN.

HAVING read with astonishment Mr. Munn's attempt to drag me into the disgraceful mess into which he has got himself, by imposing upon the Birmingham Committee and the exhibitors in the Black Bantam class at that Show, I feel myself more than ever called upon to defend myself from his attacks upon my character, and to show to your readers that he is now trying to impose upon them also.

It is, no doubt, very convenient to have a "man," behind whom to shield himself when caught in any kind of irregularities. Mr. Munn says that he left home "in the middle of November"—we will call it the 14th or 15th, and bind him down to that time; also, that I "sent two birds on approval," which is correct. He says he was away from home on their arrival. If so, why did his "man" use the following words in his letter of advice to me when they were returned?—"Mr. Munn desires me to say that he does not see the value of £2 in either of the birds."

Then, again, as the enclosed note from the Great Northern Railway Company's office here states, the birds were sent off to him on the 5th November, and returned on the 7th of that month; so that the whole transaction was completed seven clear days before the admitted "middle of the month," when Mr. Munn says he left home. Query, Where was Mr. Munn in the interim? But, supposing he had been from home, the birds would not be sent to the Birmingham Show till the 28th, which leaves twenty-one days for his "man" to apply elsewhere or have Mr. Munn's advice in the matter; and still Mr. Munn does not scruple to tell us that his "man" "had not time to write to and get an answer from" him. Then he says "they were perfectly valueless for exhibition;" but, in the advice referred to, he says nothing at all about the quality of the birds, but contents himself with grumbling at the price.

The one, he says, had red ear-lobes, had pure black legs, was an excellent bird, had already taken first prizes at Skipton and Settle, and I bought him because of the size and whiteness of his ear-lobes; and the other has good blue legs yet, and, if desirable, shall be sent to your office for your inspection.

He says further, that he "knew nothing at all of the affair;" but, on turning over two leaves of your Journal, he says that he "claimed a pen of Geese" at Birmingham. Of course he would be at Birmingham. How, then, are we to reconcile his assertion with that fact?

When his "man" wrote to me he used the following words only, "The one we have has white legs," and never informed me that he had been claimed from me at the Crystal Palace Show: therefore I cannot see what explanation he could expect from me.

There is an old adage that "one tale is good till another is told;" therefore I shall feel it very hard towards myself if you object to retract what you have said respecting Mr. Munn's letter, exculpating him; and if he has returned the prize money to the Birmingham Committee, he has not nor is it in his power to restore the rightful honours to the exhibitors whom he has wronged.

As to the change in the natural colour of the legs of fowls, my experience as an extensive breeder and dealer tells me the contrary of your assertion. I have seen Black Polands, Bantams, and Hamburgs at the age of sixteen or seventeen weeks, with legs within a shade of black, as were the legs of the bird referred to, change to be almost white by the time they were six or seven months old. I have no doubt but that many of your readers can bear me out in this.

In a previous letter I made an assertion which you seem to doubt; but, fortunately for myself, I have invariably acted on the maxim that "two heads are better than one," and have sought advice from other exhibitors before sending a fresh pen of birds to any particular show. In the case in hand I had them examined by two whose names have appeared in prize lists in your Journal; and having washed the legs of the birds before they were sent off, they will give their signatures to the effect that they were naturally a good dark colour, and perfect in that respect, if you will allow them to do so.—E. HUTTON.

[We have omitted much from Mr. Hutton's letter, but have inserted all that is at all applicable to the subject. Mr. Munn says that he knew nothing about the Bantam's legs being blackened, and even Mr. Hutton's assumptions—and they are only assumptions—are not irreconcilable with Mr. Munn's statement. The man when rejecting and returning the Bantam cocks might say, without any criminal deviation from the truth, that Mr. Munn desired him to say what he did say, because Mr. Munn had left him to exercise his own judgment. That Mr. Munn has returned the prize money to the Birmingham Committee we know, because we have seen the Secretary's acknowledgment of its receipt. Mr. Hutton may have seen chickens' legs become lighter as they became adult; but we think he will not venture to say he has seen the black legs of an adult fowl become white as it became when three weeks older.]

May we not take the most charitable view of the conduct of both parties, and accept as truth Mr. Munn's declaration that he knew nothing of the legs being blackened, and Mr. Hutton's declaration that no colouring was put on the cock's legs sent to the Crystal Palace? There have been many instances of birds on their way from a show being changed.—Eds. J. of H.]

PHILOPERISTERON SOCIETY'S ANNUAL SHOW.

THE annual Show of the Philoperisteron Society was held in the Freemason's Hall on Thursday the 15th. The show of birds was truly magnificent in character, and in spite of some varieties not being represented, must be pronounced as one of the best that the Society has ever held. The room was almost inconveniently crowded during the afternoon. Among the company present were many well-known fanciers. In addition to the members we noticed Messrs. Bellamy, Pyne, Dean, Wolstenholme, &c., and a good sprinkling of those savants who take an interest in the variation and origin of species—Mr. Smith, the President of the Entomological Society; Mr. Wallace, the celebrated ornithologist, to whom we are indebted for the living Birds of Paradise; Dr. Günther, of the British Museum, the highest authority on the natural history of fishes; the Secretaries of the Acclimatisation Society, and many others.

Of the birds it is difficult to speak. Mr. P. Eden's *Powters* worthily occupied the pens hitherto filled by those of Mr. Bult; those of Mr. Hayne were also present at the other end of the room. In *Carriers* the Show was particularly strong. Mr. Hayne is a host in himself, and was rivalled by many of the country members. Mr. Oliver's birds were splendid in eye and style. Some of the celebrated Plymouth strain from Mr. Chalkers put in an appearance. Good birds were also shown by Messrs. Dale and Everett, and an exquisite White hen by Mr. Esquilant. *Short-faced Tumblers* were in full force. A Society which in-

cludes the names of Messrs. Lucy, Esquilant, Percivall, Archer, and others, cannot fail in these varieties. A more beautiful pen of White *Fantails* were never seen than those sent by the President, Mr. Harrison Weir, and his *Turbits* were equal in merit. Mr. Wicking's pens of *Swallows* and *Priests* were almost dazzling from their purity of colour. The *Barbs* of Mr. Eden were superb. Amongst them we noticed more particularly two Yellow cocks and one Black that for breadth of skull, shortness of beak, and size of eye we have rarely if ever seen surpassed. *Jacobins* were not in strong force as to numbers, though the quality of those exhibited was good. Among the more miscellaneous birds we may notice a singular single specimen exhibited by Mr. Archer. This bird, which came from Belgium, conjoins the colour of an Archangel with the head of an Owl or Barb, its most striking peculiarity being the extraordinary length of the tail and flight feathers, the latter crossed beyond the tail giving the animal the appearance of a gigantic Swift (*Cypselus*), or Longwinged Hawk. Mr. Esquilant exhibited a pair of very good Blue *Dragons*, and Mr. Tegetmeier a pen of Belgian *Homeing Birds*—the *Smeries* of the continent, but which are usually termed *Antwerps* in England. This pen included some young birds bred from those of M. Simonis, that won the sweepstakes in the long flight from Marseilles to Liège, nearly six hundred miles; from M. Fumel; M. Lejeune, the editor of "Le Pigeon," a Belgian journal devoted to the flying fancy; M. Rutk, and others.

Taken as a whole it was regarded as the best Show that has ever been held by the members of this Society, and as more than sustaining its ancient prestige.

The increase of the number of the members and the zeal with which they bring from great distances large numbers of birds to this annual *réunion*, proves the inherent vitality of the Society, which goes on steadily and surely progressing year after year; every succeeding Exhibition showing more birds, more pens, more members, and more visitors.

HYBRID GAME AND POULTRY.

FROM the ready answers I have seen about crossing Pheasants, I am induced to mention two crosses I have lately observed—one between the Grouse and Black Game, the other between the Guinea Fowl and the common hen. Both were so plain as to be indisputable, having characteristics of both birds. I cannot avoid remarking on the pleasure that may be derived by the interchange of knowledge and remark in natural history.—H. R.

COMMON PHEASANT CROSSING WITH THE SILVER.

SOME correspondents of your Journal expressing a doubt that crosses between the common and Silver Pheasant have never occurred, I beg to say that cases of their having done so are common enough; but excepting for the novelty of now and then shooting a sort of a piebald one, there is nothing to admire in the breed so brought about. On the contrary, I have heard gamekeepers affirm that the cross spoiled the breed, the offspring being tender and sometimes mistaken for domestic fowls, and deficient of that bold bearing which characterises the Pheasant cock of the wild breed. The half-bred differ considerably in appearance, and some may be regarded pretty, but generally they present that mongrel sort of character which is only endurable to those who have never studied the beauties of distinct breeds.—J. R.

BROWN, WHITE, AND PIED CROSSED PHEASANTS.

TWENTY years ago I had more time to spare than now, and took great delight in having Game birds in every variety as tame as could be. Breeding freely, I found no difficulty in rearing hybrids—that is, crosses between White and Brown Pheasants, Grouse cock and Bantam hen, Partridges and Bantams. I often heard of, but never saw, a cross between a Pheasant and common hen, having frequently tried and, of course, failed. Common sense and reason prove it impossible, for the Pheasant takes four weeks to hatch, the common fowl three weeks; and although reading your invaluable Journal for many years, I never saw this remark at any time.

The Pheasants must be pinioned and really tame—that is, feed from the hand and allow themselves to be handled: a run in a garden indispensable. They should be a White cock and Brown hen, or Brown cock and White hen; they must be together the whole season, or hatched together; and the hens must be of one kind. The birds produced are beautifully marked, partaking of both kinds.

I have had Snipe, Woodcock, and Plover living in my garden for a length of time, until cats and other vermin destroyed them. The plan I adopted to procure Game when a boy was to watch the hen, find her nest, change the eggs by putting Bantams' eggs instead, and the chicks, when hatched, would be as wild as their foster-mother. The wild eggs, Pheasant or Partridge, were brought near home to a secure place in a hedge, where a Bantam would take charge and bring them home when a week or fortnight old; then they are easily domesticated.—W. W., Dublin.

CROSS-BRED PHEASANTS.

I AM very glad to see the interest evinced in your last Number about the cross between the common and Silver Pheasant. It is extremely rare, but has been met with. I have never seen one. I have seen fourteen or fifteen between the common and the Golden. The late Lords Beauchamp and Hastings bred them. I am disposed to believe "S." is mistaken. The Pied Pheasant is bred between a common and a White bird. I have bred many, and have one now in my possession. The common, White, Pied, Chinese Versicolor, and Bohemian may all be intermixed, and the produce remain a Pheasant; but if either be mixed with the Golden or the Silver, the produce is a hybrid. The cross between the fowl and ordinary Pheasant is a hybrid. I have had many.—Y.

THE MOVEABLE HEN-HOUSE.

It would be a great improvement if it were possible to fatten to a convenient degree all fowls intended for the market before delivering them over to their fate; for, although the art of so raising and feeding certain breeds has been greatly advanced in some countries, they are usually handed to the merchant in very poor condition. They are often allowed to become too old; and except some chickens fed for special tables, nearly all pass without preparation from the courtyard to the kitchen.

The reason is that the farmer who breeds and raises them has scarcely ever time to fatten them. There must be a great difference between quietly allowing poultry to go and come freely about a farm, and occupying one's self with it as a special branch of the establishment.

I do not enter into such details as to decide, for example, what sort of fowls ought to be chosen. Some breeds which lay well do not produce such good chickens as others which are less famous in the first respect. It is for the intelligent breeder who understands his business to choose the sort of bird most suitable for his purpose.

In France, the towns of Le Mans and La Flèche, in the western districts, are celebrated for the fattened poultry with which they supply Paris.

I do not now tell you of the many methods of fattening adopted by professional poultry-feeders, nor even among other modes of a very ingenious machine, with which a man is able, through the help of a wheel moved by his foot, to fill the stomach of a fowl which he holds in one hand, while with the other he ascertains the vacuity or fulness of its crop.

These processes can only be employed by persons who devote themselves not merely to the breeding of fowls, but solely to the fattening of birds which they procure in poor condition from the farmers.

I wish to write of a system suitable to a strictly farming establishment, and which serves the two purposes of raising poultry economically, and of keeping down in the fields the swarms of grubs which devour their produce.

Birds of all kinds are the sworn enemies of the insect tribe. It is their special mission to restrain the natural multiplication of these creatures within such limits that man shall not suffer by their ravages. But, generally speaking, birds that destroy insects are of no use to man in the way of sustenance. Thus, then, if in place of leaving the insects to the crows and such other birds, we could have them eaten by hens and other

domestic fowls, would there not evidently be a double benefit in such arrangement? It is for the solution of this problem that M. Giot has invented his moveable hen-house.

The interior of the hen-house resembles that of ordinary fixed hen-houses. Its size differs according to the quantity of poultry which you may desire to put in it, and it is mounted upon wheels like a carriage, in order that you may shift it about more easily. It is moved by manual labour, or with the help of a horse, according to its size or the condition of the soil which it traverses. It is desirable to have it furnished with a door, which can be closed at night in districts where there is reason to dread the ravages of vermin. If there are thieves in the neighbourhood, it may be necessary to place a watch-dog in charge of the "colony."

The results of this system are numerous. Chief of these is the destruction of insects to the advantage of edible fowls, the more complete destruction of insects, and the preservation of the fowls in much better health than in enclosed courts.

For persons who desire to try this system, the following mode of procedure may be recommended:—About the middle of March, if the weather is favourable, the moveable hen-house may be placed in the field. Its inhabitants should receive one-fifth part of their food in corn, this being necessary to correct the effects of the course of worms and grubs to which they are at first apt to devote themselves too exclusively. During harvest and in autumn they have no need of such additional diet, at least in ordinary cases, but they may occasionally require water. At the end of October the spring regimen should be returned to, and on the first approach of frost the hen-house must be sent back to the farm.

During the ploughing season it is necessary to follow day after day the course of the plough, in order to destroy with certainty the larvæ turned up by that operation. After harrowing, it is profitable to do the same thing, in order to allow the fowls to pick up the grains which they find on the surface.

Several objections have been made to this system, but experience appears to have refuted them. Some farmers had expressed a fear of seeing their poultry wander; they know now that there is no danger of that. At the end of some days the birds know perfectly their own house in all its travels. Others maintained that hens, from their scratching propensities, would do more harm than good in the sown lands, where it was recommended to place them after the harrows. It is true the hen scratches, but it can scarcely be said that she is invariably a scratching animal. Thus in a court, often very small, where her eye cannot discover food necessary for the satisfaction of her hunger, she naturally scrapes up the soil; but allowed to go freely in open fields, she soon loses that habit. It is sufficient, then, in order to insure the safety of the fields of sown grain, that the fowls should not be permitted to remain too long on the same spots; for the habit which they have of digging-up the soil and half burying themselves there, for the promotion of their digestion, can do no harm to the crops if they are moved sufficiently often to prevent them burrowing repeatedly in the same place.

It is even observable that in the stations of the hen-house the crops are superior, owing, without doubt, to the better mixture of land with the manure and feathers which these animals leave there.

In respect to sown fields, M. Giot reports to the effect that he had tried such a structure as is here described, and that he was surprised to find that the hens had carefully picked up all the grubs that made their appearance one morning after rain, along with all the grains of corn that had been left uncovered by the operation of the harrow, but that they never once attempted to scratch up those which had been properly deposited in the seed-bed.—(*Scottish Farmer*.)

THE WREN FAMILY.

UNDER this heading I wish to include all those English warblers that remain with us through the winter. They are the Golden and Fire-crested Wrens, the Common, Jenny, or Puggy Wren, the Stone Chat, the Dartford Warbler, the Robin Red-breast, and the common Hedge Sparrow, known by a variety of sobriquets, as Molly, Dunnock, Shuffewing, Hedge Accentor, or Fauvette d'Hiver. These are all soft-billed or insect-feeding birds that remain in this country through the whole of the year. Some frequent the woods and heaths, while others prefer the

gardens and cultivated lands. Flying from tree to tree, or creeping along the hedges, they are continually hunting for their daily food, eating an immense quantity of insects in all stages of the development, from the egg to the perfect insect. Thus they greatly contribute to check the rapid increase of these devastators, and, consequently, confer an immense amount of good on mankind. Nor is there one of the whole family that can be accused of doing injury, on which account they should be strictly preserved and protected.

There is no fear of their becoming too numerous. Their food being always insects, they suffer severely in winter; and great numbers perish from cold and starvation in frosty weather. When the earth and bushes are covered with snow, or all things bound hard by king Frost, these poor little famishing birds become very tame, and, driven by hunger, approach the houses, pick up any crumbs or such food as they can eat to sustain life, till better times arrive, at which season numbers fall a prey to boys and cats, or die from cold and exhaustion. Under such circumstances it is pleasing to see the children instructed to collect the crumbs and scattered fragments to give to the poor birds—it speaks of a kindly feeling, and an appreciation of the sufferings of the brute creation. But this reflection is foreign to my present paper, and I must dismiss the subject for the moment, a sordid one of profit and loss. It is with respect to the *pros and cons*—concerning the good or injury rendered by birds to the gardener and agriculturist—that I have penned these articles to endeavour to undeceive those that practise poisoning at indiscriminate destruction of these little creatures, each of which has a good office to perform, and, as far as I am able, point out the benefit each may confer; nor do I omit to mention those cases which are known to me, where any of them commit an injury, or give an annoyance.

In the present instance I am not aware of any one of the above-named birds doing any damage whatever, though it has been stated by some that the Robin does sometimes eat a few currants. On the other hand, they all feed on insects whenever they can procure them, and when these fail them they must die. This, then, being the case, any person having a garden, plantation, or land, must, unless blinded by prejudice, regard them as profitable tenants, and for his own sake desire to preserve them through the winter, that they may be able to assist in keeping down the rapid increase of insects in warmer weather. It is, therefore, evidently to the occupier's personal interest to protect the Wren family, and even offer them food in winter, that he may insure their more efficient service in summer.

Although I urge my petition more particularly in favour of this class of birds, still there are many others equally deserving even among those that it is impossible to deny do some injury or cause some annoyance; and I believe that the majority do greater amount of good than ill.

Some persons think and argue, that since the destruction of Hawks and birds of prey has been so general, that small birds have become too numerous; but I consider such reasoning being somewhat erroneous, for I believe the Hawk's mission, and indeed, that of most carnivorous animals, is to destroy the aged, the maimed, and the diseased, and thus keep the stock healthy.

That Hawks when sharp set, will chase and kill healthy birds, I do not deny. Many persons, no doubt, have witnessed this fact; but very few Hawks will give themselves the trouble at fatigue of a long flight, when food is to be procured on easy terms, for a small bird naturally flies for protection to a hedge or bush, where it can easily baffle its pursuer. I do not think old birds in possession of health are often destroyed by Hawks certainly not so frequently as these theorists would desire us to believe; though young birds may often contribute to the Hawk's bill of fare, yet, I suspect he would prefer the young chicken, Partridge, which could not escape by flight, or lead him to uncertain chase.

In my opinion, it is the abundance or scarcity of food that will regulate the number of birds. When any colony of birds has so reduced the insects on which they prey in one district that living becomes difficult, they must die-off or migrate to other localities. It is the struggle for life that will ever hold its balance in Nature.—B. P. BRENT.

PRODUCTION OF WAX.—Prof. Leuckart has recently expressed the opinion that for the production of wax, pollen is of rather more significance than honey; the latter or its equivalent is of course always indispensable, and the former may at times for

of space be dispensed with; but for the rapid and abundant production of wax, both are required, and the Professor thinks that pollen is much more extensively used in the process than is generally supposed.—(*Prairie Farmer*.)

Prof. Leuckart is a distinguished physiologist, but is not a bee-keeper. If he really has expressed the opinion ascribed to him, (of which, however, I have seen no notice in the *German Journal*), I should most respectfully venture to differ from him.—A DEVONSHIRE BEE-KEEPER.]

DESERTION OF HIVES AND ITS CAUSES.

THIS is notoriously both a dull and a gay season. In the outer world of nature—in mountain, field, and garden, all is desolation, gloom, and silence. Everything without—earth, ocean, and sky—all participate in the same dismal aspect. The sun, shrouded in a sombre livery, sheds his feeble rays obliquely through the dense vapours that surround the horizon, while Boreas sweeps in a withering blast o'er hill and dale.

"All bleak and dismal look the naked woods,
The fields are strip of all their gay attire,
Peal with loud noise the cataract's heaving floods,
Nature herself seems almost to expire!"

Yes! It is only in the social intercourse of friends—in the drawing-room of fashion, or around the domestic hearths of many happy homes of "merry England" that we must look for this season for much of pleasure or amusement; in short, it is only in the communities of men, and not in the communities of bees, that we are to expect any signs of social activity or joyous manifestations of life.

At such a time as this, amid the warm greetings and hilarities of a festive season, the apiarian is apt to forget his numerous ills in the cold silent garden; or, if his footsteps chance to stray, as mine are apt to do from habit, to the apiary-site, he can only give utterance in measured plaint to the first words of a celebrated poem "How still and peaceful is the"—little bee!

A short time ago I looked into the garden of an apiarian friend, who expressed a desire that I should see his stock. The weather was comparatively mild—the thermometer standing at 52°

and we found the bees partially astir, availing themselves of the privilege, so seldom afforded at this season of the year, in our northern climate and in a large town locality, of exercising their bodily functions. Side by side in the apiary stood the yellow-banded Italian and the old English. Few bees appeared of the former; but an adjacent stock of the latter showed a considerable muster. At the first glance a curious phenomenon presented itself to my notice. A considerable moiety of those coming from the English stock were Italians; and having directed my friend's attention to this fact, he at once branded the signers as the most arrant thieves imaginable, and insinuated that, in imitation of their lords, but after a different fashion, they were no doubt interchanging the civilities of the season by buying wholesale from their neighbours' repositories. "Not so," replied; "those are not the motions or habitudes of robbers." They must have deserted from your Italian stock, furnished with the English, and are now become completely domesticated. "Impossible!" "Well, let us see." We examined the interior forthwith, and found it was even so. Of those exposed to our view, twenty per cent were of the Italian race! To this little incident the following remarks on "Desertion and Its Causes" owe their origin:—

On the subject of desertion I will be as brief as possible, and I rapidly run over a few cases which have come under my own observation, and cursorily allude to some of those chronicled by others.

Desertion of bees from their own hives may arise from various causes, some very trivial in themselves, and others of more importance. Some cases are quite easily understood, while others are more obscure and less definable in their origin and character. I shall refer to each of these, though not perhaps in the order they are stated.

The simplest forms of desertion are such as occur in the newly-hived swarm, when, if by some casualty it loses its queen, the whole bees will, as a matter of course, return in a body to the parent hive. The next form of desertion may be illustrated in the case of a hive being found in early spring minus its queen. The desertion in this case is frequently slow and gradual, and the outward evidence which even the most observant apiarian sometimes has of the fact, will be the noticing for a con-

siderable time afterwards, farina-laden bees enter the queenless hive, speedily come out again, re-enter perhaps several times, then fly away, and finally go into some neighbouring hive to which they have before allied themselves. No doubt, in a case of this kind some bees may perish abroad, and some in vainly endeavouring to gain admission to an unfriendly neighbour; but others are evidently more fortunate. I need scarcely remark to the experienced apiarian, that when such strange vagaries are exhibited by the bees of any hives, they may be considered as bad omens regarding the state and condition of that hive. I will afterwards show that in the case of queenless hives in autumn the same results will not follow like causes.

Another curious form of desertion, partial in its character, occurred some years ago with myself. In my apiary stood in summer a stock teeming with a superabundant population. The bees hung in masses around and about the hive; but they were unprepared to swarm, and therefore during the heat of the day they felt uncomfortably oppressed and restive. At noon I removed this hive for some contemplated experiment; but changing my purpose, I again replaced it on its old stance. It had only been removed for a few minutes when the bees, returning from the fields, found their way into a neighbouring hive, which they entered with a loud humming noise. When I replaced the hive on its stance there was no great disposition manifested by these wanderers to return again. The consequence was, that a perfect rush from the dense clusters hanging around the returned hive took place which I in vain endeavoured to quell; and nearly the whole outlying bees, attracted by the hummings of their associates in the adjacent hive, deserted into it, and permanently allied themselves to its unresisting population. The stock which received this unlooked-for accession of bees was thereafter converted from a comparatively weak colony to one of extraordinary industry and vigour. This form of desertion, though partial and altogether peculiar in itself, arose from a cause purely incidental. Nevertheless, I am the more desirous to notice it because I have reason to believe that in numberless instances partial desertions of a limited character constantly occur in a large apiary without the knowledge of the bee-cultivator, and without producing any perceptible benefit or injury in the hives in which they take place.

And here I may observe how much the apiarian of the present day is aided in this, as in all his other researches, into the many curious phenomena which constantly present themselves in the study of the bee, by the introduction into this country, through the instrumentality of Mr. Woodbury, of the yellow-banded Italian. It is but very recently that I became possessed of a stock of this beautiful race; but I expect to be greatly assisted through this agency in the future in investigating, in a new form some of the more abstruse and scientific points pertaining to the natural history of the bee, some of which are embraced in the German Dzierzon theory of parthenogenesis. I have no wish to speak unfairly or disparagingly of this theory; but, believing as I do that there is a great principle involved in it which, however plausibly argued by its votaries, and borne out by experiments apparently carefully and scientifically performed, yet, coming as it does into jarring collision with all which we have hitherto been accustomed to hold as essential to animal reproduction, it is right that the evidences brought forward in support of it should be carefully weighed, tested, and tried in every possible way ere it be allowed to assume a definite position in nature. No loophole should be left unexplored so as to admit of doubt, and every objection (and there are several which might be urged) should be satisfactorily disposed of, which can be fairly shown to militate against the conclusions deduced, which in some instances appear to me to be rather assumed than proved. This, however, is all by the way—a little desertion from the subject on hand, to which I must again return.

Well, a short time ago I noticed a solitary Italian bee in one of my common stocks apparently completely domesticated and fraternised. I happened to be interfering with the stock in some way, when forth came a few bees very furious and greatly incensed at the disturbance. Foremost among these defenders appeared a yellow-striped Italian come forth to resent the insult. "Ho! ho! my little friend, what are you doing here? Domesticated? Let me see." I took it on the point of my finger a considerable way off to try. There—gone! Where has it flown? To the Italian stock? No, but to its affiliated hive from whence I took it, where it was received with all friendliness.

Desertions in autumn, I may remark, are somewhat different from those which occur in spring. A stock of bees in spring

which, through some casualty has lost its queen and been unable to supply itself with a new one, will not continue to work beyond a certain period—namely, after the brood are all hatched; but it is otherwise with a hive so situated in autumn. After the usual manifestations consequent upon the loss of a queen, or their inability to supply themselves with a new one, the bees are sobered-down, through dire necessity apparently, to a kind of settled content, which has often surprised me; and more surprised still have I been by the fact, that when so left in this condition for a considerable time, I have in vain supplied the bees with materials from which they might supply themselves with a new sovereign. The eggs and young larvae they diligently tended and nourished, but too frequently have I been disappointed in their success in rearing for themselves a queen. It would be foreign to my present purpose to enter into a speculation as to the reason of this. I simply desire now to record the fact, at the same time remarking, to prevent an erroneous solution which might occur to some, that any such curious phenomena as “fertile workers” were present to affect their usual instinct in such circumstances. I have had such hives which continued to work on till late in the season, when ultimately they either became the objects of pillage, or the bees suddenly dispersed themselves and disappeared altogether. I must also observe that queenless hives can never be industrious hives, and I have never found them to add much to their honey-stores.

There are other kinds of desertion, which occur both in the spring and autumn, of a different character from any yet mentioned—namely, a desertion by the bees *en masse* from the hive in the form of a swarm, and which are usually ascribed to internal enemies—such as the ravages of the waxmoth, mice, &c., or to destitution and want. I should be ashamed myself to have had any personal experience of such strange occurrences in my apiary, from causes, implying as they do, if this theory be correct, the grossest carelessness and neglect; but, if I am to give credence to information derived from other sources, cases of desertion have occurred where none of those causes stated seem to have been present to affect the bees. As an illustration of this class of desertions, I shall merely chronicle two cases which I myself made the subject of special investigation. One occurred towards the end of March, the other about the middle of December. In answer to my inquiries as to the first case, I was informed that the hive was a second swarm of the previous year, and was apparently in a thriving condition, when, on a mild day towards the latter end of March, the bees left in a body like a swarm, and gathered on a gooseberry bush. The hive from which they issued was examined and found to be utterly deserted, but containing plenty of honey in the combs, and no assignable cause was exhibited for such a strange occurrence. In the evening, the swarm was put into the same hive and removed to its old stance again, and some food administered, but, when the hive was examined two days after, the bees were all found dead. The other case occurred about the middle of December. The hive was described to me as a vagrant swarm, found in June of the same year; and as evidence of its prosperous condition, the gross weight of the hive at the close of the season was given at 52 lbs. About the beginning of December this hive was removed from its summer site, which was stated to be an exposed one, to a warmer locality a little distance off in the same garden. The bees were observed to be frequently out after this removal, but all seemed to take to the new site well enough. On the 20th December, which was described as a beautiful day, a little before noon, the whole of the bees rushed out of the hive and clustered on a hedge a little way off from the place they formerly occupied. Some were brought back to the hive and some followed, but a cluster still remained on the hedge till evening, when the branch upon which they gathered was cut down and laid beside their hive; but the bees did not enter till morning. The weather being fine, they afterwards showed themselves reeling about, but nothing occurred to indicate anything wrong in their condition. The hive was described as having plenty of honey and a good supply of bees. To these particulars I add no comment.

I have not exhausted the subject of desertions in these remarks. There are other causes which give rise to desertion besides those already stated, upon which I cannot here dwell, such as internal damp or excessive moisture, noxious smells, old musty combs, a superannuated or diseased queen. All these may produce a gradual desertion—a dwindling away of the bees until utter ruin overtake the hive; but in these and similar instances of the decay and mortality of hives, there are other causes at work,

and which are superinduced by these internal evils which hasten the final result. Under such circumstances the queen becomes affected by the general epidemic, her breeding powers are paralysed, desertion and mortality gradually proceed, while there is no compensating ratio of increase. The results are such as might, *a priori*, be predicated in the circumstances—the speedy decay and extinction of the whole hive.

I would simply, in conclusion, remark, that there are other curious phenomena which periodically occur in every large apiary, not certainly having any necessary connection with the subject of this article, though giving rise to a very strange phase of it, and with respect to which the queen is a prominent cause. In investigating the singular phenomena to which I can only here allude, I have bestowed considerable attention and thought; and though I cannot say that I have been yet able to unravel entirely the true solution, yet if ever induced to take up my pen to endeavour to cut this gordian knot, to unriddle this physical mystery, I should describe the subject of my essay to be, “A New Chapter on the Natural History of the Bee.”—J. LOWE.

APIARIAN MISCELLANY.

(Continued from page 776.)

Or the hives in the Exhibition, taking them in the order as already noticed in your pages, I next arrive at the curious affair sent by J. Neilson, of Denmark, a very good representation of which is to be seen at page 688. I cannot discover a single advantage likely to be gained by using such a *multum in parvo* bee-shed; while the disadvantages are so obvious they need hardly be particularised. Imagine, however, eight populous colonies congregated within this contracted space; imagine, also, the door opened exposing to the light the interior of four colonies at once; having removed the glass side, proceed to manipulate on one of these, depriving it of a brood or honey comb, searching for a queen or royal cells; and imagine if you can the scene of tumult, fighting, and slaughter which would be likely to follow the desperate venture. My first impression on seeing this compound structure in the Exhibition was that it was only fit for firewood, and, used as intended by the manufacturer, I am of the same opinion still. The neatness of the outer covering of straw was, however, well worthy of remark, and by knocking out all the interior work the case would make a very nice house for one or, at most, two separate depriving-hives.

I did not observe in the Exhibition the apparatus for marking the foundations of combs on bars by forming an impression on a thin coating of wax by means of an engraved roller; but having had an opportunity of inspecting one which “A DEVONSHIRE BEE-KEEPER” constructed for the purpose, I am enabled to speak favourably of the invention, and believe it to be well adapted to the end in view.

The machines in the Austrian department for making straw or rush hives struck me as being very admirable, and worthy of imitation by our own hive-makers. By means of these machines hives of a square or oblong form adapted to the use of the moveable bars and frames can be easily made of greater thickness and stability than by the usual system of straw-hive makers in this country. Of the form of the Austrian straw hive I cannot speak so highly. Manipulation at the ends instead of at the tops of the hives is decidedly objectionable. The drawing of one of them at page 798 is admirable, and gives a correct idea of its squareness of outer form and general solidity.

I have no doubt there were other hives to be found in the Exhibition, but this includes the sum of those of which I took notes at the time. To “UPWARDS AND ONWARDS” we are much indebted for his elaborate survey of the numerous specimens of honey and wax, and their various preparations, the inspection of which must have consumed no small amount of valuable time.—S. BEVAN FOX, *Exeter*.

MACHINE FOR MAKING STRAW BEE-HIVES.

WILL the writer of the article in your impression of 30th December last, tell me how the leverage for pressing-down the straw is obtained? I suppose by inserting the moveable handle into something—but what? And what purpose does the tall upright serve, which is seen rising from behind the others in the engraving? There appear to be horizontal as well as perpendicular rows of stitches; are both put in before the piece is

removed from the machine? and what material is used to stitch with? I should very much like to apply the process with some modifications, perhaps, to the manufacture of straw "Woodbury" hives for my own use.—JOHN P. EDWARDS.

[The tall upright in the engraving to which you refer, is an iron bar 1 inch wide by three-eighths of an inch thick, firmly secured to the work-bench by means of a screw and nut, and perforated throughout its entire length with holes 2 inches apart. This forms the fulcrum of the lever which is hinged to it by means of a moveable iron pin, which is shifted upwards from hole to hole as the breadth of straw increases. The rows of stitches run only in one direction, being perpendicular in the machine, and horizontal in the hive. The perpendicular lines are perhaps rather too strongly marked in the engraving of the latter, as they merely indicate the successive layers of straw by which the hive is formed. The fabric must be properly stitched with what material you please, before it is removed from the machine. Most of the hives of this department were stitched with bramble-splits, but one or two were neatly sown with (we believe) iron wire. Now the rust from this would quickly damage the straw where it comes in contact with it, but this objection does not apply to copper, and copper bell-wire would be just the material. Woodbury-hives made in this manner, with a wooden frame an inch thick at the top and bottom, would be most excellent.]

WHINS, FURZE, OR GORSE FOR COWS.

I HAVE received a letter on this subject, and gave the plainest and the best directions I could; but both for their sake and my own, I would much prefer that any who wish for information on the subject would provide themselves with my little book, which contains so much more information on furze culture and management, and testimonials to its utility, than could be given in many letters. The price is but 8d. per single copy, or 6d. each where four are taken, besides book postage; to be had at Hartland's, Patrick Street; McKensie's, seedsman, Camden Quay; or at the printer's, Messrs. Landon, Bridge Street, Cork.

Every day I have more reason to be convinced and confirmed in my opinion that where furze is cultivated as directed in the book, it is the most valuable seed which can be sown, producing in perpetuity a greater weight of better food than treble the same extent of best meadow. My crop this year is 14 stone the statute perch, equal to 14 tons per acre. One perch sufficient for four largest cows per twenty-four hours. Sufficient seed sown in good ground in spring 1861, and this from long experience certain to improve in quantity and quality, the prickles so short and soft that (cut very short) the cattle eat it, as readily and easily as they do clover or such kinds, and those fed on it are in best condition; the expense of preparing a trifle; with pony power, that quantity is easily cut in a quarter of an hour by the £7 cutter.—(WILLIAM R. TOWNSEND, Rector of Aghadda, Middleton, in *Irish Farmer's Gazette*.)

[We recommend this to the attention of those who keep a cow on a limited space. That furze is relished by cows, horses, and other animals, and that they thrive upon it has long been known. The cavalry horses in Spain during the Wellington campaigns were never in better condition than when their forage was furze chopped small. This is no modern discovery, for Evelyn, Duhamel, Hunter, Martyn, and others record how team horses and other domestic animals thrive upon it. In the Highland Society's, and the Royal Agricultural Society's "Transactions" are many testimonials from practical men to its bullock and sheep-fattening properties, as well as to its nourishing powers as a horse food.—Eds. J. OF H.]

THE POISON OF THE STINGS OF WASPS AND BEES A "PERFECT CURE!"

HEarken unto me all you who are the victims of divers maladies; for may it not be in my power to impart unto you the knowledge that a "perfect cure" lies near at hand, to be found no farther off than in your own or your neighbours' gardens?

Oh! ye horticulturists who are afflicted with rheumatism, let us in future hear no more of your painful experiences; and all who are seized with bronchitis, or troubled with lachrymal fistula, and some other diseases of the eye, send not for your

usual doctor, but take the remedy in your own hands if you have the courage to do so.

It is simple. Let it be supposed that rheumatism attacks your right arm. Sally out, capture the first bee or wasp you can see, and straightway compel it to sting you in the afflicted member. Should the disease fly to your leg, treat that in the same manner. If bronchitis be your assailant, meet its attack, not by applying a blister to the throat, but by substituting the sting of a wasp; or, if disease of the eye be your painful portion, fly to the same inexpensive remedial agent—the poison of the stings of wasps or bees. The curative insect may well say in the words of the ancient general, slightly altered, "I came, you saw, I conquered."

Oh! shade of Sydeserff! may there not have been some truth in thy theory that the poison of a second sting counteracted the effects of the first, and that fifty stings were better than one?

In "Chambers' Journal" for December 27th, in the article on "The Month," we find a notice of the foregoing discovery. Dr. Desmarts and M. de Gasparin are the promulgators of the theory. "Dr. Humboldt, nephew of the late illustrious German, in his practice at Havana, has ascertained that the poison of the scorpion tribe is a remedy for yellow fever. He inoculated 2478 men of the military and naval garrison; 676 afterwards caught the fever, of whom not more than sixteen died."

Then with regard to rheumatism. M. de Gasparin writes, "He had long been afflicted with a rheumatism which kept him constantly infirm. One day, in picking up a handful of weeds in his garden, he was stung by a wasp on the wrist. The arm swelled, but the rheumatic pain disappeared. Seeing this result, he caused himself to be stung the next day, along the seat of pain in his leg, and was again delivered from suffering and able to walk with ease. This happened three years ago, and every subsequent reappearance of the malady has been cured by similar means; and by a wasp-sting in his neck, an attack of bronchitis was overcome."

I do not express an opinion on the value of this so-called discovery, but merely quote the assertions of these distinguished foreigners as given in the veracious columns of "Chambers' Journal."—S. BEVAN FOX, *Exeter*.

SALT FOR PIGS.

WHETHER right or wrong in my idea that salt is injurious to pigs, I am glad the subject has been mentioned. Truth is likely to be elicited by the discussion, and truth alone is my object. Feeling convinced my pigs were killed by salt, I do not feel disposed to set the subject at rest by trying its effects again; as, to say the least, it is not necessary to the well-doing of these animals that they should be fed on salted food. A friend of mine living near Peterborough tells me his servant once poured down some brine in which pork had been salted in his farmyard. There were a number of small bits of meat and fat in the brine. These scraps were picked up by the fowls and pigs, and one pig and several fowls died. I cannot think it possible these bits of flesh were in a state of decay; and if they were, would not expect fatal results to fowls, remembering how I have seen poultry pecking at carrion in a game-keeper's yard. In my own case the potatoes were undoubtedly diseased, but as they were boiled one would hardly expect them to be poisonous; besides which, I have given large quantities of diseased potatoes to pigs before and since with no ill effects. If salt was not the cause of my loss, it is at least singular that my second loss should have occurred the day after brine had been put in the swill-tub. One of your correspondents says he has seen pigs made very ill from eating salt. It would be interesting to know how old these animals were. Mine were in each case rather young store pigs. Supposing salt injurious, the power to withstand its effects may depend on the age and strength of the animal and the amount of the salt eaten. Has any one seen a pig eat salt alone when placed in its way, as sheep, deer, and oxen will do? If so, I shall believe salt beneficial. I hope some one who can afford the experiment will salt his pig before its death and report the result.—J. R. PEARSON.

IS SALT INJURIOUS TO PIGS?

To this question I should say, No; and permit me to give my reasons for making such reply.

In the first year of the potato disease (1845), I had a rather

large piece of ground planted with the variety called Birmingham Blues. I prided myself on their appearance, and had almost begun to calculate the money they would return when consumed, and in the shape of bacon. Delusive grasp! In a few days afterwards their tops were black with disease, and reeking in everybody's nose. I had never heard of the disease, and I believe they were the first in the neighbourhood to be attacked, I being more forward with them than my neighbours. The affair was so sudden, and the taking them up so sudden as well, that before the disease was mooted in the papers the Potatoes were boiled and salted to suit my own palate, and then well rammed-down in the hog-tubs; the putrid ones buried in a rippled grave by the side of the river, and the diseased haulm burnt upon the ground.

I little thought to what an extent the disease was about to spread. I knew, though, that the tubers could not increase in health or bulk by remaining in the soil after the foliage had been destroyed by so sudden a check of nature.

I lived near Ludlow then; and on the 2nd of June—I am not quite sure if it was a Knighton fair day—two of the most Cruikshankish gawky-looking pigs imaginable were bought there from the Welsh hills, for I knew it would never do to buy sleek well-bred fellows from the lowlands to fatten on the food that I should give them for some weeks to come. When they were driven home over some fourteen miles of ground they were as fresh as larks; and our neighbours' jokes flew thick as leaves in Vallambrosa on my devoted head. Jones, our parish clerk, declared he thought I had "bought a couple of greyhounds to fatten!" Well, they had their laugh, and I saw no earthly reason why they should not; and the result proved as follows:—

EXPENDITURE.	£	s.	d.	Dec. 30.	RETURN.	£	s.	d.
Bought two store pigs	3	8	0	Sold two bacon pigs, weight				
Man driving home ditto ...	0	2	6	732 lbs. at 5½ per lb.	16	15	6	
27½ bush. damaged potatoes	1	7	6	To two pigs' fry's	0	3	0	
1½ bush. of grey peas, given								
whole to the pigs a few								
at a time	0	6	4	Deduct expenses.....	11	10	4	
8 cwt. of barley meal at 10s.								
per cwt.	4	0	0					
9 bushels of barley at 4s. per								
bushel.....	1	16	0					
Grinding ditto at mill, 2s.								
per sack.....	0	6	0					
Lettuces, pot-liquor, straw								
and labour balanced by								
dung	0	4	0	Profit remaining.....	5	8	2	
Man killing two pigs.....								
	11	10	4					

It was now my turn to laugh and joke. I never had pigs that came on better than those did with the salted potatoes. I adopted the practice for two years afterwards; and I salted boiled carrots, parsnips, and yellow globe mangold wurtzel also, but I always did it according to my own palate, and I do not like too much salt with anything.

We came to this place in 1847, where, in consequence of having very near neighbours and being situated in the town, we do not now keep pigs, though we have the credit of it, for the gate-keeper next door does so; and I am often accosted by people who say, "Oh, dear, Mr. Fenn! why don't you advise the rector not to keep pigs? They smell so really offensive every time we turn the corner to go into the park?"—UPWARDS AND ONWARDS.

TEA-MAKING.

MAKING TEA.—The making of tea is a subject every one is so well practised in, that it is scarcely necessary to give directions. The essential requisites are—First, good tea; second, a good teapot—that is, one of plain shape, free from ornaments, which give a larger surface to throw off the heat, or from flutings and mouldings, which prevent the inside being wiped clean and dry after use; third, boiling soft water. When soft water cannot be obtained, a small portion of carbonate of soda is often used to correct the hardness of the water, but in general it is employed in great excess, when it renders the tea soapy and mawkish; for a large teapot a quantity the size of a pea is amply sufficient. As the making of tea is a subject in which every one is interested, we add the directions of two men almost equally celebrated, the one as a poet, the other as a *cuisinier* (or cook).

LEIGH HUNT'S RECIPE.—Dear reader, male or female (very dear, if the latter), do you know how to make good tea? because if you do not, and we have known many otherwise accomplished

persons fail in that desideratum, here is a recipe for you. In the first place the teapot must be thoroughly clean, and the water thoroughly boiling. There should not be a leaf of stale tea left from the last meal. The tests of boiling are various with different people, but there can be no uncertainty if the steam comes out of the lid of the kettle; and it is best therefore to be sure upon that evidence. No good tea can be depended upon from an urn, because an urn cannot be kept boiling, and water should never be put upon tea but in a thoroughly and immediately boiling state. If it has done boiling it should be made to boil again. Boiling, proportion, and attention are the three magic words of tea-making. The water should be soft, hard water being sure to spoil the best tea; and it is advisable to prepare the teapot against a chill by letting a small quantity of hot water stand in it before you begin, emptying it out, of course, when you do so. These premises being taken care of, excellent tea can be made for one person by putting into the pot two or three teaspoonfuls, and as much water as will cover the quantity; let this stand five minutes, and then add as much more as will twice fill the cup you are going to use. Leave this additional water another five minutes, and then, first putting the sugar and milk into the cup, pour out the tea; making sure to put in another cup of boiling water directly.

TEA—SOYER'S PLAN.—Soyer recommends the following plan, and from repeated experience we can speak very decidedly in its favour:—Put the tea in a perfectly clean and dry teapot ten minutes or a quarter of an hour before it is required; warm both the pot and the tea by placing them before the fire; then fill the teapot with boiling water; allow it to stand for five minutes, and it is ready. The method improves the fragrance of the tea very considerably, slightly but pleasantly altering the flavour.—(*Prairie Farmer.*)

OUR LETTER BOX.

DORKING PULLETS NOT LAYING (*A Constant Subscriber*).—We are disposed to think these friends are right who say the birds are over-fat; but we have done so badly ourselves with eggs, spite of every painstaking in food, change, run, age, and selection, that we give an opinion with diffidence. Nevertheless, we think we would diminish the food a little. They are fat at 7 lbs. each, and, when very fat they will not lay. In a park there is choice of natural food; but when they are very fat they will not seek it.

COLOURED DORKING COCK (*An Old Sub*).—A white feather in his tail and a speckled breast would certainly not disqualify him for exhibition. Colour is only essential for Dorkings in the silver-Grey classes. One white spot is enough to disqualify if shown as a Silver-Grey.

HENS ALONE (*Ignoramus*).—They will lay as well as if a cock were their companion.

BREEDING BANTAMS WITH WILLOW LEGS (*Cochin*).—A white-legged Game Bantam cock, and a blue-leg Bantam Game hen, probably would breed chickens, some with white and some with blue legs. We see no reason for thinking they would throw willow.

FATTENING FOWLS (*Idem*).—Ground oats mixed with milk form the best food for fattening fowls or Turkey.

BLACK BANTAMS.—"WILTSHIRE RECTOR" recommends "C. G." to obtain a sitting of eggs in the spring from Mr. Baily, of Mount Street: they would be from pure birds. Good Black Bantams are somewhat rare, and consequently dear. Mr. Baily's cheapest are 10s. each.

DORKING PULLETS AT MANCHESTER (*An Exhibitor*).—We have made the necessary inquiries, and find that you are totally wrong in your suspicions. Under any circumstances, such suspicions could not have been published until you had communicated to us your name.

DUCKS FOR TABLE (*Alpha*).—The Aylesbury is the quickest fatterer. It is not so hardy as the Rouen. The Buenos Ayrean is the handsomest; and, although not as large as the others, it is a prolific and profitable bird. That we recommend.

OAT-BRUISED MILL—SPANISH FOWLS (*N. F.*).—We do not know of a second-hand mill for sale. An advertisement in our columns would perhaps find one. You will in all probability breed good pullets from the cock with a falling comb, but they will produce you lop-combed cocks when you breed from them again. In our opinion it is always a pity to breed from faulty stock.

SPANISH RUNTS SUFFERING FROM COLD (*H. B. P.*).—If the birds are kept fairly warm and well fed, they will soon recover. If the discharge from the nose and eye continues, give a capsule containing a dose of mixed balsam of copaiba and cubeb. This acts as a specific on the diseased mucous membrane, and effects a cure sooner than any other remedy we are acquainted with.

DISEASE IN SHORT-FACED ALMONDS (*Almond*).—The conditions under which you keep your birds appear so perfectly satisfactory that we can only attribute the tubercular disease of the liver to hereditary causes, or to close interbreeding carried to a great extent. We should suggest a change of your present matches, and, if possible, an infusion of new strains.

LIGURIAN BEES (*L.*).—Write to T. Woodbury, Esq., Mount Radford, Exeter, who will give you every information as to price, &c., of Ligurian stocks.

BOTTLE-FEEDER FOR BEES.—There is an error in the reply to "One Who Has Bees." Thirteen lines from the bottom of col. 1, p. 42, the neck is spoken of as "enveloped in the neck," instead of in the *net*.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 44.1° and 30.7° respectively. The greatest heat, 57°, occurred on the 1st, in 1852; and the lowest cold, 8°, on the 31st, in 1857. During the period 144 days were fine, and on 108 rain fell.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 44.1° and 30.7° respectively. THE IMPROVEMENT OF CLAYEY SOILS.

HAVING observed that you have recently had to reply to several inquiries concerning the improvement of clayey soils, I have thought that my experience in so important a matter might be acceptable to your pages, and, I hope, instructive to those of your readers who may unfortunately have to supply fruits and vegetables from a garden, the soil of which is a rank clay. Those alone who have had that disheartening work, and the almost insurmountable difficulties to combat in producing from such a soil all that is generally expected as the produce of a gentleman's garden, can fully realise how exceedingly desirable it must be to carry out any process which will change a stiff, tenacious, damp clay to a more friable and fertile staple.

When I entered on the care of the gardens at Dyrham Park some fourteen years ago, the worthy proprietor had previously decided to burn a very considerable extent of the soil, which was of a more clayey description than any that ever I had seen enclosed with garden walls. Capt. Trotter took the idea from the Great Northern Railway Company in their operation of burning in that neighbourhood immense quantities of clay, turning it into something like pounded bricks, for the purpose of putting between the rails instead of gravel.

Accordingly when I went to Dyrham, the burning process had been commenced, and a patch or two had been burned and cropped. But the method pursued was simply to burn a heap in the centre of a quarter, taking the soil just as it came, top and bottom spit, round the fire, and then to spread it generally over the surface, and crop it. The summer being a very hot and dry one, vegetation simply existed among so dry and porous a material, it being more like red brick-dust than anything else.

After having satisfied myself that this burning process, if properly carried out, would prove a thorough renovator of so terrible a soil to work, and having been informed that the garden was well drained, I set about the work of burning to a large extent; and I cannot here do better than describe the mode of burning in the words made use of on a previous occasion.

As soon as a quarter became vacant, a fire or two was started, according to the size of the quarter. When only one fire was required, it was, of course, started in the middle. The site for the fire was first trenched to the depth of 2 feet 9 inches, turning the top spit (which had through a long course of years been improved a little by liming, the addition of ashes, road-scrappings, &c.), into the bottom of the trench, taking out the two bottom spits for burning. So thoroughly clayey was the greater part of the soil moved, that the men had to dip their tools in a

pail of water at every lift, to make the next spadeful slip off the metal. On this site the fire was commenced. Wood which was only fit for charring or firewood, and which is generally plentiful enough about most gentlemen's places, was used. In that locality coal was costly, and not so effective in this case as wood; the latter also affording in burning a desirable quantity of potash. The site for the fire being ready, a little stack of wood was formed 5 feet in diameter at the base, tapering conelike to the height of 5 feet, beginning with a few dry faggots in the middle, and finishing with stronger junks of wood round the outside. All round this stack of wood a coating of the clay was laid on to the depth of about a foot. It was found best to pack it on in lumps as it was turned out of the trench. When this was done the wood was set fire to at the centre, and long ere the wood was all consumed the clay caught fire and burned freely. As soon as the first layer was nearly burned through another layer was added all round, which in its turn soon burned through also. The fire was then broken down with a strong iron-handled hoe, for the double purpose of adding more wood to quicken the fire, and enlarging the basis of operations. After the fire was thus set agoing the wood was of necessity laid horizontally over the burning heap, putting the strongest pieces of wood next the burning mass, and finishing off the layer with the smallest, to prevent the clay from lying too closely to the wood and obstructing the draught necessary to combustion.

In the meantime trenches were opened at the extremities of the quarter, and the clay taken out, as already described in making the site for the fire, and forwarded to the fire, there being the solid undisturbed surface to wheel it over, and the distance lessened as the fire became larger and required more feeding. But to return to the fire. When it was again found necessary to break it down for the purpose of extending the base, and increasing its capacity for consuming the clay, another layer of wood was added, and then a layer of clay over the surface, and all round the outside of the heap. After this, as the layer of clay was burned through, another was packed on all over and round without any wood, and so on with two or three layers, till it became necessary to enlarge the base of the fire, by drawing it down from the top, then more wood was added; and from the great power which the fire attains it is necessary to have plenty of clay and men at hand to cover over the wood quickly, or it would be consumed without doing much good; and so this process was continued till the necessary quantity was burned. I have frequently had three great fires going at a time, on to the tops of which I have wheeled layers of clay to the thickness of 3 feet and more at a time. When the fire became powerful it formed a solid pile of fire, which very soon worked its way through thick and successive layers of clay, transforming what was once an insoluble, wet, tenacious paste, into a heap of material greatly altered in its mechanical properties, and with a great capacity for the absorption of ammonia, besides being mixed with charred wood and potash.

As soon as the heap was sufficiently cool to be moved

it was wheeled back over the surface of the quarter and regularly spread, and the large lumps broken-up. On the surface of all was wheeled a garden rubbish-heap, rotten leaves, road-scrappings, dung, and any other decayed vegetable matter that could be obtained. A trench was then opened at the end of the quarter, and the whole was turned over and mixed the same as is done with a compost-heap, to the depth of the original clay, which was forked-up as well as it would allow at the bottom of each trench. This formed a staple on which almost any crop that could be put on it in the way of vegetables grew with such a luxuriance as I have never seen equalled either before or since. I have seen Brussels Sprouts over 4 feet in height, studded with hard sprouts more like a rope of Onions than anything else. Peas, Cauliflowers, &c., were amazingly fine crops. One quarter which I burned in 1854 had the finest crop of Carrots that could be desired, and to have attempted such a crop on it previous to its being passed through the fiery ordeal, would have been in vain.

The expense attending such an operation as that just described, will, of course, occur to the minds of those whom such a matter may concern. I am sorry to say that I can give no accurate estimate of the expense per acre, as no account was kept of the cost. This, however, I know, that it is not so much as some might imagine. In my case, with the exception of two extra labourers the first autumn and part of the winter, the whole of the work was done in the autumn and winter by the ordinary allowance of men for the place, and the money value of the wood consumed was not worth thinking of, as it was simply such as was fit only for firewood. I feel convinced there is no other way of overcoming so well the difficulties and unprofitable labour connected with such a soil.—DAVID THOMSON, *Archerfield Gardens*.

KEEPING ICE.

ABOUT this time last year this campaign concluded in articles of peace, I believe, to the satisfaction of us all, and to the good of our readers. Much of prejudice and preconceived notions was removed, and the practice and science of the question were proved and vindicated the one by the other.

The subject being a very cold one, I take it the temperature of the parties engaged in the strife is by this time sufficiently near "temperate" to admit of the chronicles of the campaign being written by one of the combatants. But that was not what induced me to write about ice to-day, for I had not the smallest intention to blunt a pen on it this season until the middle of January; but having read the article on "American Ice-houses" at page 31, as extracted from the *Canadian Agriculturist*, I have swerved from my purpose; more especially because an innocent gentleman, whose good opinion I am very jealous about, has been led into a mistake about my views on ice-keeping by one of those common blunders which none of us can account for.

Mr. J. Anderson, of Meadow Bank, Uddingstone, in the west of Scotland, is the gentleman I allude to. He was not a reader of the first volumes of the old COTTAGE GARDENER, where is recorded the reason why we drifted into that war. The "why" is briefly this.

The old ice-house at Shrubland Park, in a steep bank of pure white sand of very great depth, never did keep ice since it was made, about the time the Duke of York reviewed the volunteers there, which the first baronet of Shrubland raised to resist the threatened invasion of the first Napoleon. My predecessor, Mr. Lindsay, then from Highclere, introduced the ice-stack system about five or six and twenty years since, and was very successful with it. He told me it would be of no use trusting to the old ice-house, nor did I, and for the next fifteen years the ice-stack never failed once; and we never reached the bottom of it in any one year till the foundation had to be regulated for the next start.

This ice-house, however, was filled and used as a game-larder and kitchen-garden preserve, just as the Canadian farm has it. I had not the least merit as regards the ice-stack; I did it exactly as Mr. Lindsay told me. The expense of forming it and obtaining the ice daily from it for three or four months was not one-half so much as that of putting the ice into and taking it out of the ice-house, from which a bucket of ice was never drawn in my time.

When my tether was nearly run at Shrubland, a great landed gentleman, the owner of Helmingham Hall, in Suffolk, who had just finished a new castle in Cheshire, told me his architect made

him an ice-house there all above-ground, and thoroughly ventilated from end to end, and that ice kept better in that way than by the old plan. I ventilated the old house, which never would keep ice, and for the next three years it kept the ice just as well as the stack; so I had no merit in the question at all, unless it was to battle with prejudice against scientific truth, as I always did and will do.

The ice-house which Mr. Tollemache's architect made—J. Tollemache, Esq., M.P. for Cheshire—is as near as possible like the American ice-house transferred to our columns the week before last—so near, indeed, that the said architect must have had his notions from Canada, or else the Canadians had a leaf out of THE COTTAGE GARDENER some dozen years since. But neither Mr. Tollemache's architect, nor the Canadian farmers, nor yet your humble servant, ever said one word about ventilating ice at all, and there was where all the cause of the war lay, and through that lucky mistake the war had room and scope enough to last for twelve years.

I saw how the tide was likely to flood the cellars and the cobwebs, and I went quietly and put it on the record as early as 1851, that in all this ventilation no particle of air must reach the ice. In Vol. V., page 148, for December the 5th, 1851, you will find it written thus:—"Currents of air to carry off the vapours arising from the slow melting of the ice are the prime consideration in ice-keeping; and confining the passages by any means to prevent the escape of these vapours is a fertile source of waste and extravagance. Those who have read the way in which this was proved and explained, may be curious to know whether we have since made any alteration or improvement in the plan. To which I may reply, None whatever. There has been a strong current of air passing over the ice day and night, summer and winter, ever since; but some have misunderstood the plan so far as to suppose that the air-currents are allowed to reach the ice itself." That was the lucky mistake which brought so much and such good grist to my mill, and did I not grind it as well as any ice was ever ground, or pounded by pond or brook?

"To suppose that air-currents were allowed to reach the ice itself. That, indeed, would be worse than the whole mode of stifling, by which so much ice was formerly wasted." Of course it would.

Mr. Bailey, of Nuneham Park, gave a plan this time last year (Vol. XXVII., page 379), of an ice-house, ventilated as I described then, 1851, but not quite so efficient. Mr. Bailey calls it an American plan that is in use at Lord Lilford's, in Northamptonshire, and Lord Jersey's, in Oxfordshire, "for carrying off the condensed moisture, which hourly would be exerting its wasting influence on the ice." That is to say, the principle on which Mr. Tollemache's architect built the ice-house in Cheshire was applied by these noble lords and their agents to the old ice-house, just as was done at Shrubland fourteen or fifteen years ago, and with the same result.

You will see by the plan that these noblemen did not adopt the marrow of the American plan, by not letting off the air by the highest part of the roof, the crown of the arch over the ice, so they have to regulate the ventilation to the state of the weather. But the Canadian of this, our current Volume, page 31, has it in the true American style; but from that description those who are not much acquainted with the forms and fashions of ice-houses may find it very difficult to understand the whole process. I recommended the architect's plan very much at the time; also, the conversion of the old ice-house to that principle; and there is another most useful feature attached to this present Canadian ice-house which it would be treason on the part of a captain not to recommend and bring more prominently before us, if only to prevent another twelve-years war on a wrong scent: therefore, I do hereby recommend with all my force, that ice-houses should henceforth be built in this country above-ground, and on the plan and principle of that Canadian ice-house at page 31 of this Volume of the Journal. It is far more difficult to preserve ice in Canada than in England, seeing the summers there are so much warmer than with us.

The ice-house in Cheshire was built aboveground like a cottage so much in length, breadth, and depth, with brick walls, two end gables, and a span-roof. The ice was filled-in to the height of the side walls, and was covered with straw; the whole space in the roof was empty, and a ventilator in each gable, near the ridge, secured a current of air through the empty space from end to end without touching the ice at all, for warm air will never sink an inch into a cooler stratum, if it has a free course on the higher level, as in that instance.

The present Canadian-house is on a slope; it is 18 feet long, 15 feet wide, and 14 feet deep, with the bottom 4 or 5 feet sunk in the earth. The filling, or ice, is up to the height of the walls, then a straw covering on the ice, and above the straw 6 feet of empty space under the span-roof, to speak in garden language. A ventilator is in the ridge of the roof at one end, and a door in the bottom of the wall at the other end, and just within the door a four-foot-square space is fenced-off from the ice, that space being open as high as 14 feet, the top of the ice, and then communicating with the six-foot empty space over the ice.

Now, that empty space at the end of the ice-house is the Canadian dairy and store-room for things requiring to be kept cool, and the door into the dairy is opened on an average—say so many times a-day. Every time that door is opened a volume of hot air, sometimes at 96°, 4 feet square, rushes into the ice-house, then up the “shaft” 14 feet, and along the top over the ice to the ventilator in the ridge at the other end, yet that large volume of hot air so passing from the very bottom of the ice at one end to the top, and along the top to the other end, does not affect the ice in the least—that is to say, a column 4 feet square and 20 feet in perpendicular height is only separated by a covering of 6 inches in thickness of sawdust, and so much straw from the ice, and yet the farmer tells his brother proprietors from actual experience, and through their own organ, the *Canadian Agriculturist*, that an ice-house constructed in that manner “is one of the best investments for a farmer.”

But an entirely new turn has just taken place on the question of ice-keeping. Many people have run away with the idea that they could keep a few loads of ice in a stack, or in a shed, or in some kind of underground contrivance. There are three such attempts on my books from my own part of the county of Surrey, and the same tale has been told at our office—all a dead failure, of course, and all also arising from this driving of warm air full against the heaps of ice. Now, I must say in earnest that to attempt to preserve twenty, thirty, or forty loads of ice is only throwing money under the ice. I said fifty loads are about the smallest quantity that should be tried; but I was very wrong in the calculation—I forgot the difference between a load of ice and a load of sand. Can any one tell me the quantity of ice that should be in a load of it?

As far as I know, a load of ice is no given quantity at all. A Scotch cart will carry as much in one load as two of many English carts. When I said fifty loads of ice I meant the bulk of fifty loads of sand or fifty solid yards. The probability is that it would need seventy-five common cartloads of ice to make the fifty loads, or fifty solid yards in my calculation. But suppose you start with sixty fair good loads of it for a trial. I should not like to trust the packing of it, or the openings to get to it and from it, to a person who was not a thoroughly good hand at that branch by previous experience.

If you calculate the capacity of that Canadian ice-house—the good-investment-house—it will make you open your eyes if your notions are under a hundred loads in a lump. Just calculate how many solid yards or loads are in 18 feet by 15 feet, and 14 feet, the dimensions of the said house, and then take from it the quantity made by 4 feet square and 14 feet in depth, and you will find the quantity of ice is comparatively enormous.

After all, ten to one if that Canadian landholder is not a Scotchman, and, if he is, he only followed the best practice of my countrymen to a better issue; for, if you recollect, that Scotch gentleman whose good opinion I am so particular about—Mr. Anderson, of Meadow Bank, told us about this time last year that the best contrivance he had seen in the west of Scotland had four hundred loads of ice in it, and their carts there and their Clydesdale horses are much better for the purpose than we could find in England. That was, indeed, the best contrivance we had in the whole campaign—a kind of rustic shed on the north side of a wall; but recollect, the walls in Scotland are of stone, and are so much thicker and so much better for putting ice against than brick walls—that should be allowed for in the calculation.

As far as I can make out, bricks are the very worst of materials to put ice against; they absorb moisture fast and keep it as long afterwards as there is any damp or wet within the influence of their sucking powers. But just think of the difference between twenty English cartloads and four hundred loads out of a Scotch cart! I have kept under a hundred good cartloads in a stack till ice came again; and the expense of harvesting it could not be much more per hundred than where the four hundred loads were put, for the carts took it to the spot. D. BEATON.

FLOWERS OF THE LAST SEASON.

GREENHOUSE PELARGONIUMS.

In these railroad days it is hard work to keep up with things at the rate at which they go. Every one seems pushing on at express speed. Competition is endless; and we have hardly time to take our cup of coffee before the bell rings and we are off again, protesting all the while that it is very hard lines to be allowed no breathing time. It is so, I am sure, in gardening. One set of new flowers is hardly grown, notes taken of them, and determination to let all the world (because, of course, any one who is somebody reads *THE JOURNAL OF HORTICULTURE*), know about them, when lo! another little lot comes in to put their noses out of joint; and I am sure if flowers were all sensitive plants, they would feel quite as sulky as does Master Knickerbocker when he finds the baby boy with which he was so delighted at first has absorbed the attention which he alone formerly received. It seems a long while ago since the Pelargoniums of which I now write were exhibited as seedlings; and I believe in the present instance this feeling is greatly increased, owing to the superior excellence of the seedlings of last season. We do not much care to know about anything, good though it may be, when we know that there is something much better of the same sort coming on; and the year 1861-62 was not particularly distinguished for the excellence of its seedling Pelargoniums, although there were some flowers of real merit amongst them.

It is, of course, well known that Mr. Charles Turner, of the Royal Nursery, Slough, stands A1 as the letter-out of new Pelargoniums, Messrs. Dobson & Sons being the only other firm from whom they emanate, they only letting-out their own seedlings; while Mr. Turner, in addition to those he raises himself, has on his list the flowers of those well-known raisers S. W. Hoyle, Esq., of Reading, E. Foster, Esq., of Clewer Manor, and W. Beck, Esq., of Worton Cottage, Isleworth. It is of their flowers, then, that I now specially write, as Mr. Turner has most kindly every year furnished me with plants, and thus given me an opportunity of ascertaining their merits which I should not have otherwise had.

The gradually-widening circle of Pelargoniums has now reached four distinct sorts—the Large-flowering, Fancies, Spotted, and French or Bizarre—odd-looking flowers, which, however, tend much to the gaiety of the house from their profusion of bloom. The first-named class being, however, I think, the more general favourites, instead of naming all those which were sent out in the autumn of 1861, I shall rather select those which seemed to me to have any peculiar merit.

LARGE-FLOWERING PELARGONIUMS.

Arcturus (Beck), this is one of those brilliant scarlet flowers which are always attractive. The petals were well held together, and not inclined, as some are, to become loose and open.

Alba Regina (Beck), a pretty flower of Fairest-of-the-Fair style of growth. With me the blooms were small, although the colour was very pleasing.

Celeste (Hoyle), this was one of the most novel of the new flowers, the colour being a brilliant orange maroon with clear white centre. A fine plant of it was exhibited by Mr. Charles Turner in one of his collections, and was greatly admired. With me it had an inclination to crumple in the top petals. If this defect should disappear it will be a great addition, owing to the beauty of its colour.

Mrs. Hoyle (Hoyle), another very beautiful light flower; the colour a sort of light violet rose; small black spot on the top petals. A large and free-flowering variety.

Princetta (Hoyle), one of those painted flowers which are to my mind so very attractive, and this was a fine variety of the kind; very dark top petals, in fact, rich glossy black, with a narrow crimson margin; lower petals richly painted with rose and dark red.

Sylph (Beck), a nice, neat-looking flower; white ground, with purple on top petals.

Lord Chancellor (Foster), a nicely-shaped flower; the lower petals richly painted; the top ones dark maroon; centre of flower white.

Patroness (Turner), a large white flower, somewhat in the style of Ariel; crimson spot on top petals. The habit of this plant is excellent.

SPOTTED PELARGONIUMS.

Cyrax (Hoyle), lower petals rosy lilac, maroon spots; centre of flower white.

Diophantus (Turner), a large showy flower, bright red with maroon spots, but apt to run we think.

Leo (Hoyle), bright orange rose. A dark and showy-looking variety.

Mira (Beck), rose with white edges, black spots on the five petals. A very free and pretty variety.

FANCY PELARGONIUMS.

Emperor of Morocco (Turner), rich mulberry, lilac throat and edges; fine form and substance. A very dark and striking variety.

First Favourite (Turner), deep rich maroon, with white throat and margin. Very pretty and somewhat new in colour.

Undine (Turner), a large rosy lake, with light throat and edges. Very fine show flower.

These are, I think, amongst the best of last year's flowers; and now, as I look at the weeding process that has taken place in my little tumble-down greenhouse, and see how few of the large batch of last year I have kept, and watch with some degree of interest my thirty or forty new varieties which, through the kindness of Mr. Turner and Messrs. Dobson, I see now pushing their way on my shelves, I wonder what their fate will be—whether the observations of cynical critics on the new ones were true, that they were so dressed and handled, that it would be no more possible to recognise them when under different hands than it would be to recognise the old dowager when, her false hair, and teeth, and rouge laid aside, she appears rather fitted for being a member of that “ugly club,” immortalised by the “Spectator.” I do not believe in such *saur kraut* remarks, and look forward with much pleasure to seeing each beauteous novelty expanding its charms before my eyes. Still, if it be so, it shall be duly chronicled, my simple object being to give reliable information, so far as my own judgment goes, on all these various matters; and I am sure the cause of floriculture, as, indeed, every other cause, from the very highest of all, that of the truth itself, is better advanced by fair and honest statements than by any flattering or one-sided views.—D., Deal.

VENTILATION OF HORTICULTURAL STRUCTURES.

AMONGST the many topics to which public attention has been directed of late years that of ventilation has attracted its full share, and treatise after treatise has been written on the subject. Sometimes new and startling theories are advanced but to be refuted, and other theories in turn put forth until, I fear, it may be said that the laws which govern the circulation of air are but imperfectly known. However, the spirit of inquiring abroad has elicited much useful information, and although we are far from being perfect in the practice, an advance has been made, and inquiry being again afloat it is likely not to rest until some useful results are secured.

Taken in a comprehensive sense the term “ventilation,” or the due admission and distribution of wholesome air, is more important than may at first be supposed. It is also a subject of much greater difficulty than many imagine. Look, for instance, at our coal mines, and see the lamentable accidents that take place from time to time, and this, too, in spite of all the precautions that skill and science could adopt to avert such a calamity. But ventilation below ground is not the subject for our consideration, our province is fortunately on the surface; but even as regards this much diversity of opinion exists, and now and then extreme views are put forth.

Some years ago a great authority in such matters, to whom the ventilation of the Houses of Parliament was entrusted, startled the world by propounding a new law on the subject of currents of air, and some of the law courts in other parts of the kingdom then building were submitted to his mode of treating them. One of the peculiarities of this I remember, in one place at least, was that the windows were closely fastened down, and on the Judge complaining of the heat in court on a warm summer's day, he was told the windows were purposely so fastened by the designer of this mode of ventilation, on which his lordship very properly exercised his own judgment in the matter by directing his attendants with their long wands to break the glass. This was done alike to the comfort and amusement of the court; and the plan of the popular champion of ventilation of some twenty or more years ago fell to the ground, and has been since generally condemned, and the old and certainly far-from-improper

notion that vitiated air finds its way to the top, and that it ought at once to escape there, has been revived.

Various and manifold have been the means adopted to attain that end; not the least useful are those simple contrivances we so often see in the smoking-rooms of taverns and other places, which very often assume an ornamental shape, and sometimes also are turned to account in another way. By far the prettiest feature of this kind I ever saw was in the coffee-room of an inn at Truro. The ceiling of the long room was crossed in the centre by a highly ornamental open-work cast-iron girder forming an elliptic arch, and in substance about a foot thick. I believe, but am not certain, that this girder carried a wall and stack of chimnies above; but suffice it here to say that its appearance was good, adding importance to rather than detracting from the noble room it was placed in, and I believe it answered admirably. Doubtless its ends communicated with the outward air.

Taking glass structures as a whole, it is easy to conceive that in the generality of these a certain influx and efflux of air must at all times be going on; and in some old-fashioned houses, where the squares of glass are small and the interstices open, the quantities of air admitted by such means must be very great, while, it is needless to say, as much internal air must be ejected. This influx and efflux will be the greater in proportion to the difference in the temperatures in the internal and external air; and assuming for argument that the occupants of the house require a night temperature of 60°, it follows that a larger proportion of outward air is sucked into this house on a cold frosty night than on a mild dull day. This, of course, is at the expense of the mode of heating adopted: hence the more-recently-built houses are a nearer approach to being air-tight, the overlaps being fewer and much closer, and the framework made to fit as well as it can be made. But serious as is the loss of heat in one of the old-fashioned houses spoken of, if the necessary warmth required by the plants inside can be maintained, there are many plants which do better in such a position than when in a more fashionable and more air-tight dwelling: hence we often hear of gardeners lamenting how well certain plants did in the rickety old house compared with what they do in the new one—and this is no illusion; for such plants as require a continuous refreshing of pure air, its circulation cannot be too great when accompanied with the genial warmth they also stand in need of. All plants cultivated in our hothouses are nevertheless not alike in this, some requiring the close confined atmosphere of the stove, while others delight in the more open breeze.

It would be tedious in an article of this kind to go into the history of each plant. Let us, therefore, just take a rough survey of the contents of an ordinary plant-stove—such, for instance, as we often meet with in gardens that may have two or three houses devoted to the culture of plants. In such a house it is not unusual to find some Ferns, Orchids, hard and soft wooded plants, with bulbs and creepers, and probably some succulent plants as well. Now, though the amount of heat which each of these plants requires differs but little in any case, that is perhaps the only condition they agree in. The other features of air and moisture differ widely. Take, for instance, a Cactus basking in the full blaze of a tropical sun, and compare this with a Begonia, a Cissus, or a Maranta occupying the plains and densely shaded by the trees of the tropical forest; while midway between these last-named plants and the open air, as the space above the trees may be called, are nestled in the claws and forks of these monarchs of the forest some of the most lovely of our Orchids, existing as they do in a great measure on the humidity of the atmosphere which surrounds them at a certain season when they make their allotted growth and progress, while at another period the dryness of the air permits them to take their allotted rest so necessary to enable them to commence their duties again with vigour at the proper time. Compare these widely-conflicting conditions of the plants we endeavour to cultivate, and the wonder will cease that some of them do not answer so well as could be wished. A steady uniform warmth is associated with an idea of comfort; but it is at variance with all Nature's works, and as such ought to be received with caution. But periods of steady treatment are as necessary here as elsewhere, selecting the proper time from the known history of the plant to give this. That much is done in this way cannot be denied; but the mixture of subjects in an ordinary plant-house prevents the treatment being carried out to the full extent necessary to the individual welfare of each plant contained therein.

Taking another class of plants occupying a glass structure, we have also very wide dissimilarity of climates to reconcile in an artificial abode. The gales, might we not call them hurricanes? which move the plants almost to uprooting them, that occupy the crests of a mountain region like the Cape of Good Hope and elsewhere, differ so widely from the more calm abode of plants occupying the flat plains of Australia, and elsewhere, that we need not wonder at a Cape Heath being affected with mildew when subjected to the dull murky air of a closely-pent-up house; while in the latter, such plants as occupy the temperate region exempt from storm, and, probably, like the *Calceolaria* and Chinese Primrose growing under trees, are more at home here than when subjected to strong currents of air. That there are many intermediate classes of plants is superfluous to admit, and it is from the numbers of them and from other sources that our general treatment of the whole ought to be guided. Let us see how this has been done, or rather let us see in what way the best results are likely to ensue, having reference to the other conditions necessary to be observed at the same time.

If we take an ordinary lean-to house in summer time, we shall see that if it faces the south, the amount of heat it receives from the bright glare of sunshine is immense; and if no outlet be made for the escape of this heat, it will speedily increase beyond the endurance of the plants inside.

An ordinary frame or pit, with the glass and woodwork fitting closely, speedily becomes heated to an inordinate degree, and many a batch of Cucumbers have fallen victims to not receiving fresh air in time; large houses, where the volume of air enclosed is large in proportion to the heating surface, become heated less quickly, and, consequently, the plants within them suffer less; so that close attendance on the air necessary for frames is an important part of the duties of the gardener in charge. Thus the amateur must bear this in mind, and not be led to think that a small object requires little attention, for in the matter of frames or pits, and houses, the former suffer most if not attended to in time. The practical man knows this full well, and he often takes a sort of half-and-half precaution, by leaving at all times a little opening, not sufficient to meet the wants of a bright sunny day, but enough to provide against a little bright weather that may occur in his temporary absence.

To reduce the proper time of giving and taking away air from a number of glass structures devoted to different purposes, to anything like a regular tabular form or scale, is to attempt to revert to the practice of our grandfathers, whose adherence to the figures of the thermometer has been long since set aside. So many local and other conditions also militate against this, that we cannot give even general instructions on the matter without allowing for the many exceptions that are likely to arise, not the least being the different aspects of the structure requiring air, the plants cultivated therein, as well as the time of year, and, in fact, many other considerations of a similar character. Thus, a lean-to house, or a frame, facing the south-east, will require air to be admitted long before a similar structure that faces the south-west will want it. So, also, the proper time for shutting-up the one will be long before that of the other.

Some other conditions also must be considered, and some classes of houses require less air to be given them than others. A span-roofed house, with the gable facing the south heats much less quickly than a lean-to; while amongst the latter a Grape-house, with the roof well covered with foliage, is much slower in becoming hot than one less covered. The condition of the external air must, in a great measure, determine the time and circumstance of giving air, and the character of the heating apparatus has also its full share of influence; for, be it remembered, that in general the greatest number of plants in a growing condition benefit most by plentiful admissions of external air, tempered, in some measure, before coming in contact with them, but that such admissions are at the expense of the heating apparatus. It is, therefore, with a view to save the latter, that most houses requiring artificial heat are shut-up early in the afternoon, in order to shut-in as large an amount of sun heat as possible. The heat shut-in may often be from 20° to 30° more than the minimum night temperature.

Many other considerations often have to be attended to, the expense of fuel being a great inducement to shut-in as much sun heat as the plants will bear; and, in the case of frame plants not receiving heat from other than the fermenting material of the bed, it is advisable to shut-up early in order to save all the heat. Covering the glass over soon after with mats on an extremely frosty afternoon will, in a measure, prevent the escape of much of the heat.

Houses, where there is a scarcity of coal or other heating material, may be treated in like manner; the character of the outward air and the appearance of the evening determining what is best to be done. I may, however, say that in very severe weather, there is no harm in almost all houses being allowed to fall from 5° to 8° lower than what at other times is regarded as their standard.

Greenhouse plants will take no particular harm at 36°, nor those of the stove at 50°, while in milder weather they may be 10° higher.

I only point out these facts to the inexperienced, but they must not take any further liberties until they have learned by experience how much plants will bear.

I may say, in conclusion, that the garden structure requiring the least amount of fresh air to be given, is the cutting-frame or propagating-house; a close confined atmosphere favouring the formation of new roots. A Fern-house also requires little air, and so does one devoted to the growth of Orchids; while Pines, Cucumbers, and Melons, being tropical fruits, require much less than those from the temperate regions of the earth; but the time, and mode of giving air, the quantity, and many other particulars are too much for the present communication, so I must defer noticing them until another opportunity.

J. ROBSON.

HORTICULTURAL SHOWS IN THE NORTH OF IRELAND.

At page 25 of THE JOURNAL OF HORTICULTURE, "A PRACTICAL GARDENER" communicates some strictures on horticultural shows in the north of Ireland. Lest some of your readers should form a bad opinion of us here, I trouble you with the following remarks.

He says he was desirous of advancing the interests of horticulture in his own immediate neighbourhood, but was disqualified from attending one show from the fact of his employer not being an annual subscriber to the Society, and blames the Committee, some of them gentlemen's gardeners, for it.

In the north of Ireland, gardeners are not recognised at the shows to the same extent as in England. The plants are not entered in their names, neither do their names appear prominently in the award cards. The societies are kept up by annual subscriptions, and, to insure an interest being taken in the exhibitions, none but subscribers are qualified to compete. Surely "A PRACTICAL GARDENER" can find no fault with this, as it is calculated to promote the interests of local horticulture, the only object local societies aim at.

Speaking of another Society, he objects because he was not permitted to carry off more than one prize in each class. Every one at all acquainted with horticultural societies is aware of the universality of a rule to this effect. He is dissatisfied also, because the second best dishes or collections were awarded second prize, "no matter how inferior." This was not the fault of the Committee but of the Judges, who, in all cases, are authorised to withhold prizes should the subjects not be of sufficient merit. But, it fortunately happened on this occasion, the Judges were of a more liberal mind than "A PRACTICAL GARDENER," and did award the prizes, as an inducement to further care and attention on the part of the gardeners.

With regard to the last part of his communication. On one occasion, in the north of Ireland, a rule was enforced that all prize fruit was to become the property of the Society, but money prizes more than treble the value of the fruit were offered as inducements to competitors. The fruit was retained for a special purpose, which was publicly known, and surely there was no compulsion in the matter. "A PRACTICAL GARDENER" might or might not have competed just as he pleased. This happened some time since, and was the only occasion on which such a rule was carried out for the last twenty-five years.—HIBERNICUS.

MISTLETOE ON THE OAK.—Having read in one of your late Numbers an article on the Mistletoe, in which you speak of its being rarely found on the Oak, and do not name any place where it is still to be seen, I write to tell you that there is a fair-sized plant of it growing on an Oak on the land of H. Howard, Esq., Thornbury Castle, near Bristol, and which has been there for several years—marvellously eluding the ruthless hand of Christmas decorators.—CONSTANT READER.

COCOA-NUT FIBRE DUST AS A COVERING FOR HOT-WATER PIPES.

I THINK if your correspondent, "J. M.," (page 32) were to read Mr. Beaton's remarks in the previous Number of your Journal, page 3, he would discover that the cause of the cocoa-nut refuse not becoming hot was its being allowed to become too dry. I have experienced a similar instance. Last spring I covered-up my hot-water pipes with this refuse, taking care to keep it wet, particularly where in contact with the pipes, and it answered admirably.

For the last six weeks I have not been able to attend to my little propagating-house, and my man, who is no gardener, suffered the refuse to become dry, and, consequently, he could not make it hot. On removing it I found about 2 inches thick round the pipes completely caked, very dry, and lighter than cork. I made the whole quite wet with warm water, and again covered-up the pipes about 10 inches thick, plunging pots in it as before. I now find the surface very little warmer than the temperature of the house, but on lifting the pots steam immediately rises, and the stuff is very hot near the pipes.

In another part of my greenhouse I filled-up the space from the ground to the bottom of the pipes to prevent the heat escaping, and then filled-up with broken pieces of brick even with the top of the pipes, making a flat surface, on which I placed a thin sheet of iron. On this I spread cocoa-nut refuse about 3 inches thick, sprinkling it with warm water occasionally to keep it moist, and by so doing I obtain an even and regular heat over the surface.

I have been informed by an engineer that if this refuse is made quite dry, it is the best nonconductor of heat that could be used for covering-up steam boilers. I have also heard it recommended as a casing for cold frames or pits. About 3 inches thick will keep out the severest frost; but it must be made quite dry and kept so. Gardeners and agriculturists are using this cocoa-nut refuse very freely; but we shall probably hear of its being applied to other purposes soon.—H. E.

CHEAP CROCUS-HOLDER.

I AM unaware whether any of the readers of the Journal have ever seen the following cheap Crocus-holder; if not, the description may be of some service; it is, at all events, no very costly experiment to try.

Take a large sound Turnip, and hollow it out from the bottom, taking care not to injure the base of the leaves, and allowing the rind to be at least half an inch in thickness all round; then bend a piece of wire (zinc is best from not corroding) into a circular form, and place the Turnip upon it, leaves downwards, having previously trimmed-off the large ones. The hollow is then to be filled with silver sand, a Crocus root planted therein, and three wires or strings attached to the ring to support the whole upon a hook fixed in the upper part of the window-frame. The sand being kept moist, the Turnip will soon shoot-out leaves, which, turning upwards, in a short time completely hide the root, and present a pretty

and novel appearance during the winter season.—A CORRESPONDENT.

GLOBE ARTICHOKE NOT QUITE HARDY.

I CAN testify that the Globe Artichoke is not able to stand a very severe frost unless protection be used. I well recollect having in my apprentice years—it must be at least twenty years ago—seen all the plants in a large quarter of the garden destroyed by the frost, which was very severe that winter. The plants had no protection. The soil in which they were growing was a very light, gravelly, dry, porous loam, upon a sandstone sub-soil, with an angle of about 25° to the north, situated six miles and a half west of Edinburgh.

So far as I then could judge, those plants must have occupied the same ground for several years, the stools being very large and producing a very large quantity of excellent heads.

It had been formerly the practice there to have the Globe Artichokes protected, but this had been omitted that winter.—JAMES REID.

INFLUENCE OF POLLEN ON THE APPEARANCE OF SEED.

Few facts in vegetable physiology are more remarkable than the well-ascertained influence of the pollen of one species or variety on the seed and fruit of another species or variety whilst still attached to the female plant. There are several old accounts, and the case has been well proved by Gärtner of the colour of the pea in one variety of the Garden Pea, being changed by the direct action of the pollen of another differently-coloured variety. So, again, the famous St. Valery Apple tree produces many different kinds of fruit, according to the nature of the pollen used; for the singularly-constructed flowers yield no pollen, and they are annually fertilised by a party of French girls, who bring pollen from other trees, and mark with ribbons the flowers thus fertilised. About a year ago Mr. Beaton gave an analogous case, far more remarkable than any hitherto recorded, for he showed (if my memory does not deceive me) that the pollen of one species acted on the footstalk of the seed-capsule of another species, and caused it slowly to assume a position which it would not otherwise have acquired. I forget the name of the plant, and have vainly spent an hour in trying to find the passage, though I am sure I marked it. Will Mr. Beaton have the kindness to repeat the statement? and I am sure it is worth repetition. If he grant this favour, will he inform us whether his observations were made on several flowers, and during one or more years? I remember some difficulty in finding the name of the plant in such catalogues as I happened to have at hand, which led me to suppose that it had, like too many plants, more names than one.—CHARLES DARWIN.

[In answering Mr. Darwin's question, allow me, first, to clear myself of any participation in his opening remark, that "Few facts in vegetable physiology are more remarkable than the well-ascertained influence of the pollen of one species or variety on the seed and fruit of another species or variety while still attached to the female plant." Gärtner never proved that—he only asserted it; and when he was pushed to the proof, he lowered his sails, made a second edition of his great work, and confessed many of his errors.

The most practical cross-breeder who has yet appeared has stated "Gärtner's report of the cross-bred seed he has obtained, to be nothing but a mere enumeration of the crosses he has tried to obtain." And with regard to very many of the cases of impregnation mentioned by Gärtner, he, the said cross-breeder, otherwise Dr. Herbert, "utterly repudiates the probability of such impregnation;" and well he might.

It was not Gärtner, but Dr. Wiegman, in 1823, who first said he found the Pea changed colour from being planted along with *Vicia sativa*, or common Vetch; and Gärtner, two years subsequently, said he caused the same change by means of the pollen; and our Mr. Knight was somewhat smitten with that doctrine.

I had a commission to work over, again and again, every experiment mentioned by Gärtner, Wiegman, and Lageret, and I found over and over again each experiment was without a base. Others proved the same, but it remained for the late Professor Henslow to prove by scientific investigation that the pollen has no visible effect on the seed impregnated; and no cross-breeder of any practice in England at the present day would like to have his name associated with that of Gärtner, for or against any exploit in crossing. Nevertheless, I am firmly of the opinion that Gärtner was right in his belief of the way impregnation is effected.

I forget the plant I mentioned last year as having the peduncle, or stalk, of the flower affected by pollen. Of all the plants I recollect having mentioned, for the last twelve months, there are only five genera that are affected that way—*Corbularia* and *Hermione* among the *Narcissi*, and *Erodium*, *Pelargonium*, and *Geranium*, in that class of plants. The best generic distinction for upholding *Corbularia* and *Hermione* as distinct from the true *Narcissi*, is that the peduncle rises slowly from a horizontal to an upright posture as the seeds ripen in the pod. The *Erodiums* and a section of *Pelargoniums*, with, I believe, all the true *Geraniums*, have the peduncle affected differently from the great mass of *Pelargoniums*.

It is probable, however, that Mr. Darwin has been thinking of

what was said on the different stages of impregnation at page 330, of Vol. XXVII., the part for this time last year. And I think Gärtner's idea of how the pollen acts is proved both by the *Erodiums*, including *Pelargonium*, which is not a natural genus, and the true *Geraniums*, inasmuch as the footstalk of each flower in all that mass of species, and in their endless varieties, is the first part that is affected by the pollen. Indeed, I am quite certain of that, for I had at least ten thousand proofs of it. But let me explain.

Take any of the true species out of all the *Geraniaceæ*, cut off the stigma before the pollen can intrude, and the peduncle of that flower will retain its original or natural posture till it decays. A Tom Thumb, or any of the bedders, will prove that very shortly. Take another flower in the same truss, and cross it with the pollen of another species which you know will not cross with it, and the peduncle will turn to the opposite of its natural posture, and will never regain the true position, but die ultimately, as the process of fertilisation went no farther than to affect the footstalk. The next stage is the quickening of the pod, the next that of the lobes of the seeds, and all this may be, and yet no life be given to the embryo of the seeds.

Early next May any one may influence a hundred flowers of the Scarlet Defiance *Geranium* as far as the footstalk of its flowers, but no farther. Every flower of that one kind which is crossed by its own pollen, or by foreign pollen, will, in eight or ten hours, reverse the posture of the footstalks; but the seed-pod is not reached by the contents of the pollen, and the consequence is no seed and no rising of the peduncle. There are many seedlings which will prove the same as Defiance at the end of October, and through November.

Notwithstanding these facts, one can conceive a state of climate which would render the effect of that same pollen active through the three or four stages of impregnation, and produce fertile seed from Defiance. Indeed, the pollen of some kinds or varieties, which will only affect the footstalk very early and very late in the season, will effect a cross in the middle of July; and I have obtained, and I believe I am the only one who has done so, a real cross from Scarlet Defiance, which is over fifteen years old; but I may be mistaken. The case of *Cybister*, or "The Tumbler" *Nosegay Geranium*, is a different sport altogether, the truss comes naturally in a reversed position, and takes from three weeks to a month to make a right round change of position.—D. BEATON.]

THE GRAPE CONTEST.

ROYAL HORTICULTURAL SOCIETY'S FRUIT COMMITTEE.

A SPECIAL Meeting of the Fruit Committee of the Royal Horticultural Society was held on Wednesday last, to decide the challenge offered by Mr. W. Thomson, of Dalkeith, through the pages of the *Florist and Pomologist*, to Mr. Tillery, of Welbeck. Some discussion had taken place between these two eminent gardeners as to the relative merits of old and new Grapes, Mr. Thomson having succeeded in producing new Black Hamburgs on New Year's-day, and he held that new Grapes were preferable to old ones. Mr. Tillery advocated the merits of the old or *hang* Grapes against the new, and for some time an interesting and exciting discussion was kept up, one or two other members of the upper stratum joining in the discussion. As if to bring the subject to some tangible form, Mr. Thomson stated at page 70 of the volume of the *Florist and Pomologist* just completed, "If Mr. Tillery has no objection, and we are spared till the time, I will send newly-ripened Black Hamburgs to any of the January or February Meetings of the Fruit Committee of the Royal Horticultural Society, and he can send his best Black Grapes, for Hamburgs and Muscats could not well be compared in point of flavour, and let the Committee decide which are the best Grapes in point of flavour."

Accordingly, there being no regular meeting of the Fruit Committee in January, this special Meeting was appointed, which was numerously attended both by members and visitors to witness the result of the contest. Mr. Thomson sent three beautiful bunches of new Black Hamburgs which were ripe on Christmas-day. The bunches were of good size, well set, wide-shouldered, and shortly ovate. The berries large, and some of them quite hammered; but, though quite black, the colour as a whole was not so intense and even as in the bunch sent to us last year. This, we are told, has arisen from the dark, dull, and gloomy weather they had in Scotland during the whole of the

autumn, when the season was more unfavourable than any that has been experienced for some years. Nevertheless, the Grapes were so beautiful that the Committee decided first of all that in appearance they had the advantage over the bunches of Black Hamburg, of Black Tripoli, and of West's St. Peter's that were exhibited by Mr. Tillery. These, too, were as good of their kind as could be seen anywhere, but the shrivelled appearance which had begun to set in contrasted unfavourably with the plump fresh-looking new Hamburgs. Then came the question of all others, the most important in the decision—flavour; for it was on this point that the issue hung. After a very patient and very close comparison the decision was in favour of the old Black Hamburgs. Having begun to shrivel, and the juice being inspissated, the sugar was more concentrated than in the new. The question then arose as to the general merits of old and new in regard of appearance and general utility, and the decision was in favour of new Grapes. We confess to a leaning in that direction ourselves, for we think there cannot be a doubt but that fine, plump, and fresh Black Hamburgs, with their fresh, crisp, green, stalks, are more attractive, pleasing to the eye, and much more sightly at table than Black Hamburgs that are shrivelled, and from which the rigidity of the bunch and berry stalks has disappeared. Even in point of flavour the difference is so slight that it has to yield to the other qualifications. Altogether the discussion was a very interesting one, and no doubt the public will duly appreciate the opportunity that Mr. Thomson and Mr. Tillery have given them of coming to a decision on the subject.

In addition to those exhibited by Mr. Thomson, there was a small box containing several bunches of new Black Hamburgs from Mr. McKenzie, of Kemp Town, Brighton. These, though not so large either in bunch or berry as Mr. Thomson's, were as black as jet and covered with a dense bloom; a finer "blae" we never saw. But the climate of Brighton is a very different one from that of Dalkeith, and the amount of light in the one place during the winter months is very much greater than in the other, and hence the difference in colour. The flavour of the two was, however, very close; the very black berries of Mr. Thomson's being equally rich in flavour with Mr. McKenzie's.

Three magnificent bunches of Muscat of Alexandria were exhibited by Mr. Tillyard, gardener to John Kelk, Esq., of Stanmore Priory. So large and so beautiful were they that the Committee unanimously awarded Mr. Tillyard a certificate of commendation for meritorious cultivation.

Mr. Tillery also sent a splendid bunch of Trebbiano and some nice bunches of Muscat of Alexandria shrivelled nearly to raisins, which were very rich and sugary in flavour.

Mr. F. W. Pack, gardener to G. H. Vernon, Esq., Grove Hall, East Retford, sent a fine bunch of Black Barbarossa; and Mr. James Fowler, gardener to the Earl of Harewood, sent some very nice specimens of the Charlesworth Tokay, from which it is clear that this variety, if at all different from Muscat of Alexandria, is only a slight variation from it.

Mr. John Cox, of Redleaf, exhibited dishes of a seedling Pear which he has found to be very useful, from its ripening in succession from the beginning of December till now.

Mr. Francis, of Hertford, exhibited a seedling Apple, which, however, did not possess any merit to recommend it.

WALKS.

(Concluded from page 51.)

MATERIALS OCCASIONALLY USED FOR WALKS.—I have seen many miles of excellent walks made of small coals, and nothing forms a more compact one. It is also sufficiently porous to allow the water to pass through, and it is infinitely superior to chalk, which, however, ought not to be used alone. Mortar rubbish has been already spoken of, and the waste of quarries of different kinds, some excellent materials being often found on the top of sandstone. Sand itself mixed with a harder material is not unfrequently used; and where it is sharp and gritty, and of a suitable colour, it makes a good walk for many private places where there are no wheeled carriages and not very many foot passengers. Burnt earths of various kinds are not so good, they get dirty and cling to the feet; but the fact of a new walk being dirty after the first rain is not enough to condemn it, for the after rains will wash many of the earthy particles to the bottom, leaving at top the sharp and gritty portions, which are clean and do not cling to the feet. This remark, I may observe, holds good with all walks, excepting those, perhaps, that are

coated with newly-washed material, as sea and river gravel, and such like.

FOUNDATION FOR A WALK.—Whatever may be the surfacing material, it often happens that it is not in sufficient abundance to allow the whole depth required to make a walk firm and dry to be all made of one kind: consequently, a common article is used in the bottom, and not unfrequently the bottom of a walk becomes a useful receptacle for many things that are unfit for anywhere else—broken crockery, glass bottles, clinkers, brickbats, stone, and mortar rubbish, &c., that are useless elsewhere. Clinkers and mortar rubbish, or brickbats with mortar adhering to them, are about the best bottoming for a walk, being so distasteful to worms, while they allow the drainage to pass freely through. I cannot say I admire chalk so much, although it is often used. Mixed, however, with other things it will be useful; but the materials of the locality will, in general, determine this matter.

BOTTOM OF FOUNDATION.—Unimportant as this may seem to many, I am convinced there is no point in walk-making of so much consequence in some places; I, therefore, make no apology for placing the subject in its proper light, which is best done by detailing the practice I have adopted.

Being entrusted with the formation of a carriage road and large court entrance, which, as is often the case, was on the dampest side of the house, and the subsoil as stiff and impenetrable a clay as could well be supposed, I did not excavate and remove so much of it as many might have done, but carefully removed a part, leaving the bottom in a sort of ridge-and-furrow plan. The furrows were about 6 feet apart, and the inclination from the ridge 2 or 3 inches, the ridge itself not being more than 4 inches from what was intended to be the surface of the road; so that only 4 inches of metal were wanted on that part, while on the furrow it was 6 or 7 inches, and in the furrow itself a clean-cut drain was made, in which ordinary two-inch drain-pipes were placed. These were not deep, excepting at one end, to which it was necessary to convey the water. There the tops of the pipes might be a foot deep, perhaps, while at the other end they were close to the surface of the furrow. The ridges were pared smooth and true to shape, and all the material carted away, including that from the drains; and the whole was covered over with stones larger than ordinary road stones, the drains being filled with the same. Care was taken not to disturb the incline of ridge-and-furrow system into which the whole was cut; no carting over it was allowed until it was covered with stone. A finer description of stone followed, and finally the top-dressing, and the whole acted very satisfactorily. The water which fell on the top, or what might be conveyed thither, for the place was low, passed quickly through the stratum of the road, and the inclination of the smooth clayey foundation carried it into the furrows, whence it was conveyed away by the drains, which all united at their lower end. A walk may be formed on the same principle, the foundation declining to the centre, along which there might be a drain as described above; or, if the walk be wide, there might be two drains, as I have on more than one occasion made. This precaution, however, is only necessary on those tenacious clays which retain all the water that falls on them. When the ground is of a contrary description this plan of preparing the foundation surface is not necessary, and for walks a less depth of material will do. The only difficulty to guard against in shallow work is worms finding their way through and disfiguring the walk. As a preventive, therefore, use mortar and lime rubbish, cinder or clinker rubbish of any kinds noxious to worms, and, in default of all these use stone or chalk more abundantly; bearing in mind at all times that, although a smooth and level surface is wanted in walks at all times, they ought nevertheless to be porous, and by no means ought water to stand long on the surface of a walk, neither ought it to remain below, or it will always be damp, and moss and dirt will be engendered.

CONCLUDING REMARKS.—The ordinary routine of frequently rolling walks is so often alluded to in the weekly instructions given in this Journal as not to require any further notice here. Walks, however, require to be broken-up betimes, in order to destroy the moss or discoloration that comes on their surface; this is best done in winter, the surface gravel only being broken-up with a pickaxe, or, it may be, a strong fork. This brings some fresh gravel to the top, and, being carefully levelled, it again forms as good a walk as ever. A much more difficult matter is to keep the weeds down. Handweeding is strongly advocated by many in preference to salt, as the latter undoubtedly en-

courages damp more or less; but where there are large breadths to do, I confess not knowing anything so expeditious. On this subject, however, I expect some one will give us an article at some early time, detailing the results of a chemical substance cheap, efficacious, and not causing the damp complained of in salt. In Devonshire and Cornwall I have seen a substance like green sand that is found in the mines, spread over a paved yard to kill the weeds, and it effectually did so. I think it partook largely of copperas, or some mineral poison of a like kind. I have also seen a refuse of arsenic used in a similar way; the latter however is, perhaps, as objectionable as salt. I would, therefore, invite others to give us their experience in this matter; and as the subject of walks has extended to greater length than I intended, that on roads must be deferred till another time.

J. ROBSON.

GRAPE-GROWING IN AMERICA.

I FIND, by a perusal of THE JOURNAL OF HORTICULTURE, that considerable attention has of late been paid in Britain to some of the phases of Grape-growing, and some valuable opinions have been elicited concerning the different points of merit to be considered in judging a bunch or dish of Grapes produced at an exhibition, from all which I trust some world-wide standard of excellence will be erected, contributing to assist judges in impartial decisions and to the satisfaction of exhibitors.

As I have derived much valuable information from these pages, I make bold to submit to your readers two experiments I have made lately with the Grape Vine, always bearing in mind the difference of climate, soil, &c., between Britain and America.

In March of last year I renewed the outside border of an established house of Grapes here, cutting-off all the roots right up to within 2 feet of the Vines, which are planted inside, but derive very little support from the inside border. I raised the bottom of the outside border 18 inches, and cut a fine crop of Grapes from the Vines in August and September last. The leaves flagged a little during some of our scorching days in May; but by attending closely to ventilation and keeping up an abundant supply of moisture in the house I escaped without a scorched leaf.

This I had precedent for, having seen Mr. Fleming do the same when under him at Trentham, but with this difference—Mr. Fleming renewed his border before the Vines were quite rested in the autumn, thus giving the roots a hold during winter ready for a start in spring; the better way no doubt, but as I only took charge here in the preceding October I was prevented from strictly adhering to precedent.

Being much encouraged by success in this instance, I determined to try if I could not also produce new Grapes on New Year's-day; so, having cleared one house of Grapes in the third week of June, I pruned and started it in the first week of July, the temperature at the time often ranging up to 98° or 100° in the shade. The Vines bled very little, and broke very regularly. There were thirteen rods of Black Hamburgh and two rods of Muscat of Alexandria in the house. I soon found there would be no difficulty in ripening them by the time specified, as our fine genial fall, or Indian summer, brought them along very rapidly, and as the cold weather set in I, of course, took care to place ample protection on the outside border; for by the middle of December we had the thermometer down nearly to zero.

The Hamburgs bore a very fair crop, and are now (New Year's-day) quite plump in the berry, and as black as sloes, the leaves being as green and fresh as they were three months ago. I have furnished both Hamburgs and Muscats for Mr. Hoyt's table to-day, this being the grand reception-day in New York.

Strange to say in this dry climate mildew is a great pest to Vines, and has to be very carefully guarded against. I find strewing a little fresh guano occasionally in the house to be a good preventive.—DAVID FOULIS, *Gardener to Edwin Hoyt, Esq., Astoria, Long Island, New York.*

A FEW DAYS IN IRELAND.

WOODSTOCK.

THIS charming, romantic, and richly picturesque demesne of the Right Hon. W. F. Tighe and the Lady Louisa Tighe, is situated about ninety miles from Dublin, seven miles from Thomastown station on the Waterford and Kilkenny Railway, and close to the pretty village of Innistioge. In the days before-

the union, Innistioige sent two members to parliament. It was deemed of so much importance as to be besieged by the soldiers of Cromwell, and it possesses now the Ivy-clothed massive ruins of an old castle, or, rather, cathedral, which is said to have been built nearly nine hundred years ago. Close to these ruins, reminding one so forcibly of ancient times, the Catholic and Protestant places of worship stand lovingly side by side. It is no part of our duty to refer to the religious differences which have exerted such a baneful influence upon Ireland; it was a much more pleasant thing to be delighted with proofs that the largehearted kindness of Christianity was undermining and rooting-up the narrow-minded acerbities of sectarianism. Only bring men, honestly holding different opinions, into friendly contact, and it is amazing how soon they will respectively find much to admire in each other. We know little of the good people of Innistioige; but in noticing their clean and tidy homesteads, and their apparent friendliness with each other, we could not help thinking that these appearances might be somewhat owing to Catholics and Protestants worshipping the same Creator within such a short distance of each other. We can hardly imagine that, in such circumstances, pastors and people could do otherwise than exchange the courtesies of Christian charity.

Such impressions, if existing, would be deepened by the magnificent and beautiful surroundings. Nestled at the base of a hill, the village is almost washed by what Spencer styled the "grey waters of the stubborn Nore" (Nore), passing along so languidly, unless when in flood, as somewhat to resemble a rippled lake. The river here is crossed by a fine level stone bridge of ten arches; and the whole of these arches and buttresses, &c., are so draped as at once to arrest attention, fringed, as they are, with *Polypodium vulgare* and other Ferns, wreathed with Ivy and Woodbine, and dressed-out with masses of red Valerian. Above the bridge, on the opposite side of the river, the land extends in rich pasture and arable fields; below the bridge, the banks become more lofty and are clothed with timber. On the village side the banks rise precipitously from 100 to 200 feet in height, and are densely clothed with trees, with long streamers and garlands of Ivy flaunting in the richest luxuriance. Two islands are here situated in the river, also clothed with trees, the branches kissing the water, and, in their dark richness of foliage, contrasting charmingly with a row of white Poplars on the farther bank, whilst the flowing of the stream imparts a life-like reality to the whole. A turn of the river takes it now out of our sight. A gate at the village, however, admits to a fine carriage drive, between the margin of the Nore and that picturesque bank going on to the Red House, nearly two miles distant, the House and the drive being alike open to visitors.

A very steep ascent leads from the village to the entrance-gates—so steep, indeed, that Col. Tighe generally sends horses to meet the carriages of his friends. A walk almost equally steep winds to the top of the bank referred to, continuing as beautiful shaded pathways along its crest; and, on looking back whilst mounting the hill, the bridge, the river, its islands, and its banks, present numberless points of interest fascinating to the lover of beautiful combinations, and on which the eye of the painter would delight to linger.

Inside the park gates, the approach, nicely kept, winds amid lawn and park scenery, backed by lofty masses of diversified sylvan beauty. As groups in the park here, what we remember most vividly were numbers of fine-headed Hornbeam, &c., with large, natural-swellings mounds of roots, forming massive pedestals to the straight-columned boles, furnishing a fine lesson alike of elegance and fitness to those who place a beautiful vase with a handsome pedestal in their garden, and then consider it necessary to enhance the uniqueness of the colour by concealing its base with a mound of flowers! Groups of Scotch Firs, becoming bonnet-headed from age, lent their charms to the picture. The approach declines considerably to the entrance front, and thus lessens the architectural dignity of that side of the mansion; but this disadvantage is greatly neutralised by a broad level platform there, standing on which you think nothing of the descent by the approach.

With the above drawback, if drawback there be, no sooner do we arrive at the garden front, which faces the south-east, than we see at once in what a favourable and commanding position the mansion is placed. The lawn and park already referred to gradually merge into the beautifully wooded hill of Mount Alto, which rises 1400 feet above the level of the sea, and thus secures

not only warmth and protection, but forms a splendid background to one of the most beautiful and diversified of landscape pictures. On the east side of the new balustraded gardens a large space was being cleared for a new bowling-green, bounded by a miniature winding lake, with Hydrangeas, pink and blue, and giant Ferns drooping over its waters, and these backed again by trees which join those on the crest of the bank, which here conceals all traces of the river. Bringing the eye southwards, owing partly to the falling nature of the ground it passes over a wide piece of open lawn and a spacious glade, and taking in a long reach of the river, rests on the old Castle of Cluen and the steep wooded banks on the opposite side of the stream, until extending your range it takes in a great extent of beautiful elevated country, dotted with cottages and farms, terminating in the distant mountains of Wexford. On going more westward, another glade, but for its dying-out, would carry the eye to the point where the water of the glen joins the river near the Red House, which is a mile distant from the mansion. Between that glade and a third is a lake of water in the foreground, which is so managed that though of small size you might imagine it extended to great dimensions in the masses of wood; whilst the diversified foliage of the Pine, the Oak, and the Maple, &c., as reflected from its silver waters was very striking and pleasing. A great advantage of such glades besides opening-up the scenery is, that they present much of the charms of an avenue without any counterbalancing stiffness. Further westward, and in a straight diagonal line from the drawing-room windows, is the *Araucaria-avenue* backed on each side by masses of timber. Westward of this new front garden and north-eastward of the *Araucaria-avenue*, are clustered what are most interesting in a gardening point of view at Woodstock.

A very imperfect examination of what had been done and was doing sufficed to convince us of two facts:—First, that the worthy proprietors of the demesne have a refined taste for the rare and the beautiful, and liberally supported the means of gratifying that taste; and, secondly, that in the designing and carrying-out the improvements that will make Woodstock every year more interesting, they had been more than fortunate in securing the services of a gardener who possesses the enthusiasm of a poet, the eye of a painter, and the genius of the artist, united to a practical acquaintance with the principles of architecture, as well as those having relation to the different departments of horticulture and landscape-gardening. Seldom, indeed, do we find such a variety of work accomplished by one man and all done in first-rate style; and that, too, almost wholly, if not entirely, with the help of the working men in the neighbourhood. Though we cannot reach, we may well honour such talents, and more especially as Mr. McDonald is another striking instance of what can be accomplished by earnest self-denial and unremitting self-culture.

The mansion is a large, spacious, comfortable building; but until its exterior was improved it was plain rather than elegant. A portion was still covered with lime harling, which is more attractive at a distance than close at hand, and would never have done in juxtaposition with the fine balustraded garden in front. The massiveness of the walls of that garden, and the light elegant granite appearance of the mansion now, are greatly owing to the various treasures found in Mount Alto. We have already alluded to the beauty of that lofty wooded hill, planted about forty years ago by Colonel Tighe. Beautiful as it is externally, it is just as singular in its geological formations, which have been turned to good account in the new works. From this come the fine granite, and the remarkable gravels of which we shall have more to say. From the bed of the river to the top of the mountain is chiefly the clay slate formation, along with schist and quartz rock; and at the sky line is seen the argillaceous schist in contact with the granite. At this line there are a hitch and evidences of volcanic eruption, as may be readily observed by the masses of granite at this elevation so isolated and thrown out on the outside of the spur. The granite is of the finest quality. We saw large steps of it in one slab, 15 feet long and 18 inches broad; a much larger piece still was polished as a garden-seat. It is different from Wicklow granite, and some of it contains hornblende. In one part is a peculiar kind, the felspar of the deepest red colour, and in another part it is of a pearly white. Both of these are used as gravels. The white has also been largely used by Mr. McDonald for mixing with Portland cement, to imitate building with granite. It is thus that he had nearly finished giving to the mansion the appearance of a noble structure of stone. The hit, or the discovery of

mixing these materials so as to resemble blocks of granite, was a happy one, and we have little doubt will be very satisfactory. Mr. McDonald, who is well acquainted with the geology of Ireland, was agreeably surprised to find such granite close at hand, as it is chiefly confined to the coast line.

The new balustraded garden in front of the mansion is 350 feet in length and 250 feet in breadth. The boundary granite wall, parallel with the mansion, shows a height of about 8½ feet outside, facing the open lawn already referred to; at the lower end 4 feet is hidden, which would give 12 feet if all were shown. The lower courses consist of bold rock faces, and the upper courses of dressed ashlar, showing joints of 1½ inch. The height of this wall, as seen inside, is 2 feet, and it is covered by an elegant coping of original design 2 feet in width. On this, granite pedestals with neat plinths are placed at 30 feet distance from each other. These panelled blocks are 2 feet square and 3 feet in height, with a neat cornice round, projecting 6 inches. On these pedestals handsome tazzas will be placed suited to the size of the pedestals. On the end pedestals are fine granite balls, beautifully worked and of elegant design.

The wall supporting the lower side of the terrace—that next the bowling-green on the east side—is 12 feet in height outside, built also of granite, with handsome buttresses, panelled, and showing three water tables, and standing 35 feet apart. This wall is dressed ashlar with plain joints, the base course 18 inches deep; all above 12 inches. A moulded string course projects 4 inches, and on this rests a beautiful coping of original design 18 inches deep, in lengths of from 4 to 6 feet, which forms the parapet inside, and projects 3 inches over the string course. The whole of these walls testify to the best workmanship and the most refined taste.

We now step inside again. We know nothing of the previous arrangements close to the house. A low wall now separates this garden from the lower business and living rooms of the servants, so that they also may see its beauties. On this wall vases were to be placed, and a border for flowers was to be made in front, on each side of the grand iron staircase. This staircase, connecting the drawing-room with the new garden, is in the centre of the main building and the centre of the garden; it is 14 feet wide, and composed of thirteen steps, tread of steps 18 inches. These steps rest on four beams, which spring out from the house and repose on massive granite blocks 23 feet from the wall. A fine granite slab covers the ends of the blocks, and forms the first step. To conceal the iron beams at each side, there is a handsome moulded iron skirting fully 2 feet in depth, which rests at

the bottom on tables of granite finely dressed and moulded, on which Warwick vases were to be placed. This stair is of the most elegant and newest design, and was made by Mr. Turner, of Dublin, whose refined taste is well known and appreciated.

We had the pleasure of seeing the main features of this garden approaching completion, men being actively engaged in levelling the sunk panels. Besides the walk all round, the space is divided into four equal parts by a broad longitudinal walk, crossed by a transverse one; the first being opposite the grand staircase. These walks were beautifully made, verges of turf as level as a table, sloping bank, and the rest level before coming to the earth in the panel, all equally true and exact. These four panels will be 2 feet below the level of the surrounding walks. How these are to be laid out, if not already done, we cannot tell. We do not think that Mr. McDonald and Lady Louisa Tighe had then quite decided on the matter. We gathered much, that it was to be different from what generally obtains. Besides the flowers in the two borders near the house, and the tazzas and vases, mere brilliancy of colour was not to be attempted. Being directly in front of the principal rooms, it was very desirable that the garden should be as attractive in winter as in summer, and, therefore, its interest would chiefly depend on the artistic nature of the designs, and the use of dwarf plants, permanent in their character, and more distinguished for their foliage than their flowers. Such a plan would be especially desirable at Woodstock; for, as we shall see presently, there is plenty of room for floral display elsewhere. Mr. McDonald jocosely told us we must see the panels of that garden when they were finished; but if that second visit should not take place shortly, we feel confident he will kindly satisfy our anxiety, and that of others on this subject, as soon as he shall have pleased and satisfied himself. Such a system of parterres could never be tried under better auspices, and a deliverance on the subject under such circumstances would be especially interesting and important.

Not to speak of the massive walls of this garden, nearly 14,000 cubic yards of earth were brought to form the terraces, chiefly from behind the Araucaria-avenue. The excavation thus made will be devoted to a sunk drive, and recesses for ferneries and aquatic plants. The whole was moved by the hardy pony-looking horses. Owing to the suitability of the ground, this work could have been done, Mr. McDonald told us, for £200 less money by rails and waggons, but Lady Louisa decidedly preferred giving the money to the small tenants for cart-work. Need we wonder that such considerate proprietors should live in the affections of their humbler neighbours?

After some consideration as to the best mode of finishing our meagre outline, we have come to the resolution to sacrifice succinctness to variety; and will, therefore, take the accompanying rough sectional surface line of Woodstock as the key-note of our observations. Beyond A is the romantic and picturesque bank to which we have previously alluded. From A to B is the ground of the new bowling-green. At the wall at B a fine double staircase was being built, which is now finished. From B to M may be considered as a line in the centre of a gravel walk, running from the S.E. to the N.W., there being only a turn at E. From B to D is the transverse line through the width of the new panelled balustraded garden. At D is a sloping bank, and eight granite steps 15 feet long, the same width as the walk here. At E is another slope, and a rise of three steps, and 50 feet of a fine sloping lawn on each side of the walk. From E to F the broad walk is continued 450 feet. At F is a noble Beech, and beneath its shade is placed a splendid block of granite as a seat. From this the walk turns to the right to bring it in a straight line with the centre of a walled garden at G. From F to G is 300 feet. The garden is a square of 330 feet. Beyond are three terraces, I, K, L, with sloping banks, and six steps in the walk between each of them. From the upper rise at L the walk goes on to M, with a line of Irish Yews on

each side. At M is the boundary of shrubs and trees, and beyond, the line would be continued through the deer park, until it merged in the wooded hill of Mount Alto. From these massive granite steps at D, placed in the middle of the new garden longitudinally, a fine view is obtained of the Araucaria-avenue, extending diagonally as in the dotted line N. We shall leave the avenue at present, with stating that improvements were in progress for connecting it more efficiently with the new garden. Close to this place were two fine healthy specimens of *Cupressus macrocarpa* 30 feet in height, and an *Abies morinda* 25 feet in height, that were transplanted in May 1860, and no machinery used except the living machinery of Irish labourers. The sides of this main walk, from D to G, were chiefly open lawn, with such turf as is seldom seen out of Ireland, studded chiefly with single specimens, backed by irregular masses of evergreens and deciduous trees. The rain descended in torrents during the previous night; but though that walk was on such an incline, so well had it been made that there was not a wrinkle or a bit of surface gravel washed out of its place. As yet we have seen no glass, but in passing along from F to G we observe a lean-to greenhouse in front of the shrubbery, far off on the right hand, and looking somewhat lonely in its solitude.

We were rather surprised to find, amid such surroundings, a walled-in garden 330 feet square. It had previously been used for vegetables and fruit, but is now to be rightly and exclusively devoted to the latter, with the exception of flower-borders by the sides of the walks. A new kitchen garden is one of the wants of Woodstock, as the old one between the house and the river seems worn-out, and overstocked with large fruit trees. But about this walled garden. We should not like it to be removed, were it only for the position the walls afford for creepers and half-hardy plants. These walls are 14 feet in height. From the rising nature of the ground the south side rises in ramps of 2 feet, with a vase and pedestal on each rise, which give a good effect. It just struck us that the somewhat heavy effect would be much lessened if the south wall were lowered some 5 or 6 feet, ramped as now, and the east and west walls ramped to meet it, and also ornamented with vases on the rises. That ramping might be confined to the half from this central walk.

The lawn is open on the south side with a few beds of flowers in which the Prince's Feather and Love-lies-bleeding are not forgotten. The walls, especially their best aspects, were densely clothed with fine plants of Jasmines, Magnolias, Wistarias, Solanums, Smilaxes, Passifloras, Myrtles, Spireas, Escallonias, Edwardsias, Ceanothus, &c., and many unnamed things, some of good promise, sent home to Lady Louisa from friends in India and Australia. The entrances to this garden at E and G, and also in the centre of the south wall opposite a transverse walk, are by rich iron gates of an azure blue and gold colour. The sides of the walks are roughly ribboned with flowers, and rows on the sides of the transverse walk of the *Anemone japonica* were very striking, the masses of flowers being nearly a yard in width.

Against the north wall of this garden, are five lean-to fruit-

houses devoted to Vines and Peaches. The wood of the latter was in excellent order, and the same might be said of the Vines. In one house were some excellent late Grapes in September, and looking as if they would keep good for some time. The wood was also firm, strong, and short-jointed. The treatment of these Vines is one of the most singular of which we ever heard. Mr. McDonald stated that three years before they were in a bad state, all was done to coax them by surfacings, &c., and though the leaves became better, no young wood of any size would come, and from examining the roots he had little hopes of their being easily improved. There was no opportunity for a large job being done, so about the new year he set to work with a saw, and cut clean over every Vine, about 6 inches below the surface. The old roots were grubbed-up, and only a small bit of border made. Of course, every attention was paid to these old Vine-stems, and the movements of the sap watched most attentively, until the white fat spongioles were running out by the foot. The result in the autumn, as specified above, was not only good fruit, but fine healthy wood. One great advantage from such a cutting-down mode is, that like the roots from a bad cutting, the roots would all come from a common centre—a matter of more importance than is generally imagined; Mr. McDonald having proved over and over again, that two or three sets of roots will never produce fine, regular, well-coloured Grapes—a fact which should be considered by those who think they increase strength by laying the stems of their Vines in a house. We suppose we must have looked a little incredulous about this sawing-over of Vines, for we were desired to examine the cut stems, which we did, and saw the strong fresh roots issuing from above the cut part. This beats all our root-lifting hollow; but, then, we fear, it would require the attendance of a McDonald to make it answer so well and so early.

R. FISH.

(To be continued.)

RHODODENDRON JASMINIFLORUM (JASMINE-FLOWERED RHODODENDRON).

Nat. ord., Ericaceæ. *Lin.*, Decandria Monogynia. At the first exhibition of flowers at the Chiswick Gardens of the year 1850, few plants excited greater attention among the visitors most distinguished for taste and judgment, than the one here figured, from the nursery of Messrs. Veitch, of Exeter. Many excelled it in splendour; but the delicacy of form and colour of the flowers (white with a deep pink eye), and probably their resemblance to the favourite Jasmine (some compared them to the equally favourite *Stephanotis*), attracted general notice. A remarkable character of its flowers is the great length and straightness of the tube. It is a native of Mount Ophir, Malacca; elevation 5000 feet; having been there discovered by Mr. Thos. Lobb, and transmitted to the nursery of Messrs. Veitch. It seems a ready flowerer. The specimen here figured was drawn in September of 1849, and still finer flowering plants were shown at the May Exhibition at Chiswick, in 1850.

Description.—A small shrub, as reared by Messrs. Veitch,

1½ foot high, the branches bare of leaves below, and knotted where they had been inserted. Leaves crowded towards the upper part of the branches, lowermost ones subverticillate, on short petioles, obovato-oblong, rather acute, glabrous, nearly coriaceous. Umbel terminal, many-flowered. Peduncles one-flowered, short, with small reddish bractæ at the base, and, as well as the very small, shallow, obscurely five-lobed calyx, lepidote. Corolla salver-shaped, white, slightly tinged with rose below the limb; the tube 2 inches long, straight, scarcely gibbous at the base: the limb spreading, of five obovate wavy lobes, almost exactly equal. Stamens ten. Filaments filiform, downy, as long as the tube. Anthers red (forming a red eye, as seen at the mouth of the white corolla). Ovary oblong-cylindrical, lepidote, 5-celled, glandular at the base. Style rather shorter than the stamens, filiform, downy. Stigma dilated, obtuse, green. It is a warm greenhouse shrub, and its flowers are fragrant.—(*Botanical Magazine*.)

Rhododendron jasminiflorum.

THE GOOD-GRACIOUS PANSY.

I RECEIVED my share of the remonstrance against this name from Mr. P. H. Gosse in the spirit in which he gives it, and thank him for it. It is true I did not invent the name as he admits; and I trust he will believe me when I say, it is equally true that if I had thought it an "unseemly name," I should never have used it; but I never did think so, nor do I now. If there were no "essential difference" between Good Gracious and "Good God," should we say "Most Gracious Majesty?" or "Her Majesty graciously condescended to accept a nosegay of the Good-Gracious Pansy from her Grace the Duchess of Sutherland?"

The same objection was raised when the "Good-Gracious Polyanthus" came out, by the lady who owned the Experimental Garden, and who was sister-in-law to the late Bishop Blomfield. The question was referred to his lordship, and his very words were, "Cardinal Beaton is right;" therefore I would not repudiate this name.—D. BEATON.

HUYSHÉ'S VICTORIA PEAR.

THEE is, perhaps, no fruit so capricious in its periods of ripening as the Pear. The above sort, for the most part, ripens before Huyshé's Bergamot; but this season it is keeping longer than it. Mr. Huyshé writes me, that he has two or three hundred specimens that are likely to keep well for three weeks to come. What is still more remarkable, it is far superior in quality to the Bergamot, which has hitherto been considered the better Pear of the two. It may, indeed, be considered one of the most delicious Pears known.

I ate part of one to-day, January 15, and compared it with Joséphine de Malines (some of which have ripened prematurely), a standard of excellence, and was interested in the variation of their flavour, yet both delicious. The Victoria, with the melting flesh and abundant juice of the Marie Louise, has a delicious perfume, recalling that of Gansel's Bergamot. The Joséphine de Malines, alike melting and juicy, has a flavour quite peculiar to itself and equally gratifying.

It would seem, from what I learn from the reverend gentleman who raised the Victoria and the Bergamot, that the latter, this season, has been fine only from a south wall, so that it probably requires a warm season to bring out its qualities.

The Victoria is hardier and "is always good," so that it may be planted as a pyramid in any of our counties favourable to Pear-culture. This very valuable Pear is likely to supersede many of our winter varieties—such as Glou Morceau, Beurré Diel, and others, not only because the tree is hardier, but from its flavour being, like the Prince of Wales Pear (a new kind raised by Mr. Huyshé, and recently reported on by him), quite "exquisite."

Many Pears have ripened here prematurely this season. Winter Nelis, Glou Morceau, Beurré Diel, and some others ripened early in November, and were not up to their usual quality.

Mr. Scott does not give a true description, page 29, of the Easter Bergamot, or Bergamotte de Pâques. This sort keeps till April, and is always crisp, poor, and worthless.

The Doyenné Goubault is also a crisp Pear, seldom or never becoming soft, and keeping till June. This is, by some mistake, wrongly described in the "Manual," and in one or two French catalogues. The Pear is large and nearly round, like its congener, Bezi Goubault, and, like that, it will keep plump and sound till Pears come again, and may then be thrown away.—T. R.

[A short time ago we were favoured with a small basket of fruit of Huyshé's Victoria by Messrs. Lucumbe, Pince & Co., of Exeter, to whom Mr. Huyshé presented the stock of this valuable variety. In regard of flavour, we never tasted anything more rich or delicious in a Pear; and we can quite confirm the statement of "T. R." when he says, "It may be considered one of the most delicious Pears known."—EDS. J. OF H.]

FORMING A ROOKERY.

YOUR correspondent of last month will find on taking an old rook's nest from an existing rookery, and tying it securely and neatly to the top of one of his own trees, that, probably, during the next building season, others will be added to it.

I have heard that an old broom tied securely in a similar manner will attract rooks. A nest to each, or every other tree if many, as convenient, would be advisable, as I take it the knowing ones prefer an inhabited spot to solitude. It is necessary that the trees should be high and otherwise to their taste—Elm or Beech are preferred.—EDWARD NORTH.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

SONERILA GRANDIFLORA (Large-flowered Sonerila).—*Nat. ord.*, Melastomaceæ. *Linn.*, Triandria Monogynia.—Native of the Nilgherry Mountains. Introduced by Messrs. Low & Son, Clapton Nursery. Flowers in October. Colour deep purplish-crimson.—(*Botanical Magazine*, t. 5354.)

TRICYRTIS HIRTA (Hairy, or Thunberg's Tricyrtis).—*Nat. ord.*, Uvulariæ. *Linn.*, Hexandria Trigynia.—It has also been called *Uvularia hirta*. Mr. Fortune found it in Japan. It flowered in November at Mr. Standish's, Bagshot Nursery. Flowers pearly white dotted with purple.—(*Ibid.*, t. 5355.)

PITCAIRNIA PUNGENS (Spinose Pitcairnia).—*Nat. ord.*, Bromeliaceæ. *Linn.*, Hexandria Monogynia.—Native of the Andes in New Granada. Flowers, or, rather, perianths, orange red. "A very handsome greenhouse plant."—(*Ibid.*, t. 5356.)

CORYSANTHUS LIMBATA (White-edged Corysanthes).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria.—"This perfect gem" was introduced from Java by Mr. W. Bull, Nursery, King's Road, Chelsea. Flowers in October. "Decidedly the most exquisite little plant of its size, 4 inches high, that ever came under our notice." Stem transparent, its solitary leaf vividly green and white-veined; petals rich purple edged with white.—(*Ibid.*, t. 5357.)

SEDUM SIEBOLDII (Siebold's Sedum).—A Stonecrop from Japan. Introduced by Messrs. Henderson, Pine Apple Place. Leaves glaucous, tinged with purple. Flowers purplish-rose.—(*Ibid.*, t. 5358.)

DAMMARA ORIENTALIS (Dammara, or Amboyna Pitch-Pine).—*Nat. ord.*, Conifere. *Linn.*, Dioecia Polyandria.—Native of Moluccas. "Perhaps the rarest of all the Conifers cultivated in Europe."—(*Ibid.*, t. 5359.)

TROPEOLUM BALL OF FIRE.—Raised by Mr. Harman, of Uxbridge. Profuse bloomer. Flowers intense scarlet.—(*Floral Magazine*, pl. 129.)

PANSIES.—Raised by Mr. W. Dean, Bradford Nursery, Shipley. *Impératrice Eugénie*, white, margined with bluish-purple. *Harlequin*, yellow, singularly marked with purple. *Admiration*, and *King of Italy*.—(*Ibid.*, pl. 130.)

VARIEGATED SOLANUM (*Solanum capsicastrum*).—Introduced by Messrs. E. G. Henderson & Co., St. John's Wood. Leaves almost entirely pale yellow.—(*Ibid.*, pl. 131.)

CHRYSANthemUMS, LARGE-FLOWERED.—Two beautiful incurved flowers. *Her Majesty*, outer petals pale pink, inner petals silvery white. *Lord Palmerston*, dark rosy petals, silvery tipped. Raised by Mr. Salter, Versailles Nursery, Hammer-smith.—(*Ibid.*, pl. 132.)

ROSE ANDRÉ LEROY D'ANGERS.—A seedling from *Général Jacqueminot*. Raised by M. Victor Trouillard, of Angers. Introduced by Mr. Standish, Bagshot. Flowers large, cupped, very rich deep velvety purple crimson.—(*Florist and Pomologist*, No. 13.)

PLUM GOLDEN ESPEREN.—Called also *Drup d'Or d'Esperen*. Raised by Major Esperen, of Malines. First-rate dessert fruit; oval, golden colour, juicy, richly-flavoured, parts readily from the stone.—(*Ibid.*)

METEOROLOGY OF 1862.

SOMERSET.

I HAVE no doubt you have many readers who feel much pleasure in recurring to the thoughts and feelings as well as the deeds of a year gone by, and who find it refreshing to be able to fall back upon the daily remarks made in their journal for the purpose of comparing notes with other individuals at a distance, or to observe the changes made and their results on the scene of their labours. How easy to retrace our steps through the thicket or the jungle after leaving substantial landmarks on our journey through! And every one that makes his daily memoranda is fixing landmarks that will not only point

out the way he has travelled, but will materially assist him on his journey onwards.

The following remarks bearing upon the objects of THE JOURNAL OF HORTICULTURE are a few of the landmarks just as they were made in each passing month for a local purpose, and are an abbreviated copy of my journal.

JANUARY.—The new year came in dull, calm, and quiet, just as the old year passed away. On the whole, the temperature has been rather mild for the season, with a greater quantity of rain and more rainy days than generally occur when the weather in this month is considered reasonable.

FEBRUARY came in mild, and continued so up to the 6th; then frosty more or less to the 17th; to the 24th mild with misty rain; afterwards slight frosts and fine weather for commencing gardening operations. The land is healthier now than it has been for some time. A very small amount of rain has fallen during the month.

MARCH.—The first five days were cold and wintry, and rain and snow have fallen to a considerable extent throughout, with cold winds prevailing, and little or no sunshine in most places. The grass land is tolerably healthy, and with a moderately fine time in April grass will not be late; but the arable land is sodden, and, except on light lands nothing can be done towards sowing or planting with any advantage. The rain has been in an excess here of 90 per cent.

APRIL.—The month of April, considered in its seasonable character, may be said to have been favourable. Although the temperature has not been so high as in previous years, yet the nights have been warm; and the latter half of the month being free from frost with a fair amount of sunshine, great progress has been made in agriculture and gardening, and a rapid advance made in vegetation, so that the trees and hedges are clothed as if by magic, and all nature looks in a highly prosperous and smiling condition.

MAY.—The natural scenery of May is perhaps gayer and more lovely than that of any other month during the year. The botanist or the mere lover of flowers or natural scenery can make it the text-month of the year. Not a day dawns but it brings forth changes delightful to the lover of a ramble through the woods and lanes of the neighbourhood. Not a step can he take but new music bursts forth upon his ear, so that a companion is often distasteful.

Owing chiefly to the maturing character of the weather during October of last year, every spray of that summer's growth was filled with blossom-buds, so that the arboriculturists of other lands, that have been attracted through the International Exhibition to this country for the first time, must have received a favourable impression from the masses of bloom so universal during the month of May. Owing to the vast amount of blossom on the early fruits, and the favourable weather opening them almost simultaneously, the demand on the trees was too great for the supply, and blighted trees and a light crop of fruit will be the result. In other respects it has been a growing time; and the heavy torrents of rain that fell on the 29th and 30th, to more than 2½ inches in depth, have done much cleansing service, particularly in the orchards and other fruit-growing districts. The average temperature has been a little below the average, the year 1861 excepted, which was a very cold season. There have been no hot days and no frosts at night.

JUNE.—When spring has yielded to summer and the flowers are more numerous, the leaves thicker, and the grass and foliage of a deeper green, this is a most delightful month for a morning or evening ramble. It is on such evenings as closed the month, with the sun going down in all his gorgeousness and tinting the trees with gold, that the lights and shades of our neighbouring vales can be seen and felt in all their calm, silent, beauty and splendour. There have been but few such evenings during the month, and as a consequence they have been the more appreciated. There has been an absence of hot sunshine usually enjoyed and expected at this season of the year, and a preponderance of cold blighting winds, which have kept a large portion of vegetation at almost a standstill, and introduced the Potato-disease earlier than usual; but the fine weather that set-in in the latter part of the month has stayed its progress, it is to be hoped effectually, for some weeks to come. The last fortnight was good hay-making weather, and doubtless taken advantage of. On soils with a good porous subsoil the crop has been heavy, but on cold undrained lands it is light and poor. The Turnip-fly has been hitherto very destructive with all the Cabbage tribe. It is to be hoped July will prove more favourable in the Swede-

growing districts. This has been the coldest June for several years—even colder than the June of 1860, when more than 7 inches of rain fell.

JULY.—Our Anglo-Saxon ancestors called July *Mad month* (Mead month), from the meads being then in their bloom, but the month of July, 1862, has been an exception to the general rule. Wild flowers have been very scarce, and the few that have been seen have not come in due season, and the green-lane rambler feels disappointed as he wends his way in search of his favourites; but doubtless the coldness of the season has been the chief cause. The month of July is generally considered to be the warmest month of the year; but we hope it will be an exception in this respect also, for it has hardly reached the average temperature of May, and the temperature of May in the years 1858 and 1859 was considerably higher.

AUGUST.—Lammas-day. The 1st of the month is also called the Gule of August. This day, called by our Anglo-Saxon ancestors *Hlaf Mæsse* (Loaf Mass), was the feast of thanksgiving for the firstfruits of the corn; but owing to the coldness of the season there was but very little ripe corn on the 1st of the month. The weather proved more favourable than in the previous month, and, with the exception of being a little later than is usually the case, the harvest so far has been tolerably satisfactory. In this neighbourhood generally the garden fruits have been deficient and have disappeared as if by magic. Very little to be seen in the market any part of this month.

SEPTEMBER.—The weather has been very favourable for the ripening and the carrying-in of the late harvest, the average temperature having been higher both night and day than in recent years, though it has been no higher during the hottest part of the day. The range of the thermometer has been but very little, and the same temperature continuing almost from morning till night caused many people to think the weather was much warmer than it really was. The flower gardens are gayer now than they have been at any time during the summer. Although the Potato disease has not been so destructive as was expected earlier in the summer, the crop generally is small, yet the price rules low.

OCTOBER is more fertile in fruits than in flowers, and the wild nosegay gathered now is a small one, but the rambler is fully compensated in the beautiful tints the foliage is receiving during the early and middle portion of the month, but towards the close the Horse Chestnut, the Lime, and the Poplar were partially denuded of their autumnal beauties, and after a few more frosts equal to the one on the 30th, the landscape will be a barren one. The swallows and martens have left this year earlier than usual, owing, no doubt, to the extreme wetness and coldness of the season.

In an agricultural point of view, October has been unfavourable. The Swede and the Mangold have not made much progress in size, and are generally small. The land has been too wet in most places for Potato-lifting and Wheat-planting to be carried on advantageously; yet where the Wheat was planted early and now up, it is generally looking healthy.

NOVEMBER, characteristically a dull, dreary, melancholy, foggy period, came in and went out quite true to its character. It is the connecting link between autumn and winter in a meteorological point of view, which is generally severed suddenly and unexpectedly, as was the case on the 23rd, with 16° of frost and freezing all day in the shade. After this we may well say with the immortal Hood, "Where is the pride of summer?" Such an early and impetuous rush into winter, clipping autumn of its beauties, leaves him who "finds tongues in trees" dull and monotonous walks for a very long period, still during the month the weather has been more favourable than it frequently is in November. There have been no storms or hurricanes, and although there has been more than the average amount of frost, we have had a fair compensating amount of sunshine and very little rain.

DECEMBER, in contrast with the month of November has been a month of most extraordinary mildness—so much so, that its average has been considerably above that of the last thirty-five or forty years. What would make it appear more so is, that the range of the thermometer has been very small, there having been no warm sunny days or sharp frosts at night. In many places the grass has become quite fresh and green. That the weather has been pleasant is very generally admitted, but to be pleasant and beneficial are quite different matters. Undoubtedly the weather has been unseasonable, and either directly or indirectly the consequences will be felt in both animal and vegetable life;

for a mild growing time is by no means natural with short dull days and long nights.

Negretti and Zambra's patent maximum thermometer in the shade, 4 feet from the ground.

Minimum thermometer tested by the above, 18 inches from the ground, exposed.

Rain-gauge 3 inches above the ground.—THE DOCTOR'S BOY, Frome, Somerset.

EFFECTS OF CROSSING.

I NEVER saw anything of the kind mentioned by Mr. Anderson-Henry at page 46; but Gärtner and Herbert both give instances where more seeds are fertilised by a congener than by the plant itself. Dr. Herbert says ("Amaryllidaceæ," 351):—"I had a pod from *Crinum* capense fertilised by *revolutum*, in which every ovule produced a seedling plant, which I never saw to occur in a case of its natural fecundation." On the same page it is said that Gärtner "cites from Kölreuter, that *Datura Metel* and *lævis* have each about six hundred seeds in a capsule; he found that a capsule from one of them fertilised by the other contained 640."—D. BEATON.

DISTRESSED LANCASHIRE WORKINGMEN BOTANISTS.

I HAVE received, from the same lady who sent me the first lot of clothing, 100 pairs of socks and stockings, 12 pairs of cotton sheets, and 35½ yards of tweed for petticoats. This gift will enable me to give to each person 2 pairs of stockings, for I have acted on the following plan:—Where I found two grown-up females, I gave them 3 pairs of stockings between them, and the same with males, in order to make the money go as far as possible.

Next week, the botanists who have received aid in this hour of trial from your many kindhearted readers, propose to thank both you and them for such beneficial sympathy, and, with one exception, timely aid. There is one family, who, I am sorry to say, starved too long to preserve their health, and now three of the family are ill, and one has gone. The doctor who attends them assured me that their illness had been brought on by insufficient food. The parents had done everything they could to keep from the parish, and the father had only had parish relief two weeks before I made my appeal in your paper, though he had been out of work ten months, and had a wife with six young children to keep. This family has been my heaviest charge, and will be for some time, for there is no sign of the mill starting at which the father worked.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

ENTOMOLOGICAL SOCIETY'S MEETING.

THE January Meeting of the Entomological Society was held on the 5th inst., the President occupying the chair, and was well attended, considering the season of the year and state of the weather.

Among the donations received since the last Meeting, were

the publications of the Royal Society, and continuations of Kroyer's new Natural History Journal published at Copenhagen and Mr. Hewitson's fine work on exotic Butterflies.

The energetic Treasurer of the Linnean and Horticultural Societies, W. W. Saunders, Esq., exhibited some interesting varieties of Galls: one of considerable size, a Root Gall, found at the root of Oak trees near Reigate; another of the size of a double fist, found also on the roots of a tree in the Zoolu country, South Africa, by Mr. Cooper, together with a third kind, which grows in clusters like grapes on the stems of a species of *Cissus*, also in the Zoolu country. He also exhibited a species of *Bruchus*, which lives in the beautiful seeds of *Erythrina Saundersonii* in Natal, each seed being infested by from one to four specimens of these obnoxious insects.

Mr. S. Stevens exhibited a monstrous specimen of *Papilio pammon*, collected in the Sulu Islands by Mr. Wallace, one of the hind wings of which was not more than half the normal size. Also a fine species of the very rare genus of Beetles, *Psaliognathus*.

Mr. Laing exhibited a beautiful green variety of *Ellopias prasinaria* taken on palings at Charlton; and Mr. Bibbs, some remarkable varieties of Butterflies and Moths taken near Worcester, including a suffused dark specimen of *Vanessa urticae*, a nearly white variety of *Arctia caja*, two varieties of *Clisiocampa lanestris* with a large red spot on the wings.

Professor Westwood exhibited a pouch or bag of a strong leathery texture, having the outside of floss silk, formed by a colony of caterpillars (of some kind of *Moth*?) on trees in tropical Africa, communicated by Vernon Wollaston, Esq. Numerous places of exit were formed in this bag, each having the threads of which it is formed convergent, as in the cocoon of the Emperor Moth. Also a number of preparations of mined leaves fixed upon glass, showing the caterpillars within the mines, when held against the light, and which had been prepared by Mr. S. Stone, of Brompton.

General Sir J. B. Hearsey exhibited a collection of the Sphingidae of India, containing thirty-two species, several of which appeared to be undescribed; and Mr. Percy Wormold a new British species of Trichoptera, being the *Limnephilus nobilis* of Kolenati, taken at Ruislip, Middlesex.

The following memoirs were read:—

1. Descriptions of a number of new species of the Coleopterous genus *Catascopus* collected by Mr. Wallace, being a supplement to a monograph on the genus recently communicated to the Society by Mr. W. W. Saunders.

2. A memoir of considerable extent on the geographical distribution and range of the Butterflies of Europe, by Mr. Kirby.

3. A memoir on *Omalium riparium*, and two species of *Homalota*, genera belonging to the family Staphylinidae, by Mr. G. R. Waterhouse.

4. On the descriptions of Ants of Equatorial Africa contained in M. Du Chaillu's book of travels by Mr. F. Smith. In this work ten kinds of Ants are described, and accounts given of their habits, the most remarkable being that of the *Bastrykooyah* Ant, a most ferocious species which travels about in large armies, devouring everything which falls in its way, fearing not even to attack and kill the Python itself. From an examination of the accounts given of this family of insects by different authors, it became evident that M. Du Chaillu's account was concocted from Mr. Savage's history of an Ant inhabiting the same country, *Anomma rubellum*; whilst M. Du Chaillu's illustration of the species was a copy of a figure of some species of *Termes*, and did not even represent an Ant.

5. Descriptions of a number of new species of Nocturnal Lepidoptera, collected in South Africa by Mr. d'Urban, by Mr. Francis Walker.

6. A memoir on *Lucanus Lama*, of Olivier, and its synonymy by Major F. Parry.

SPARROW-KILLING NOT MURDER.

I HAVE often seen both letters and articles in the London newspapers many times, and also quotations from French journals, condemning and ridiculing English farmers for destroying their best friends, the sparrows. I am not a farmer, but I do know the difference between a house sparrow and a hedge sparrow—the latter being really the farmers' friend, but the former his most destructive enemy. The male and female hedge sparrow closely resemble the hen house sparrow, and few but

bird-fanciers know one from the other. The habits, however, are totally different. Hedge sparrows are sweet song-birds, and are to be seen in almost every garden, but never in large flocks like the common or house sparrow. The latter lives entirely upon seed; and I am sure that any bird-fancier will bear me out in saying that no one ever saw a common sparrow eat a grub, a slug, or any other insect, save and except in their breeding season. They will then sometimes eat a very few small green insects, such as are to be found upon Rose trees (I think then more as a medicine than for food); but the number they take is so few that a thousand of them would scarcely clear a small Rose tree if much blighted with these insects. If any dispute what I say, let them try the experiment by putting up a score of these birds in a room, give them plenty of grubs or any other insects they please (if nothing else can be got, mealworms can always be procured from the bird-fanciers), with plenty of water of course, and they will not find one of them alive in three days; but let them put up the same number of hedge sparrows (which have been mistaken for the common hen sparrow), give them the same food in abundance—for they are great devourers of insects of almost every kind—and they will find these birds will live, in a short time sing, and do well. If fresh-caught birds, some few of them may die from confinement, as is the case with all wild birds, but enough will survive to prove the truth of what I have written; and it is surprising to me that farmers, who have been so condemned for a supposed folly, should not have thought it worth while to disabuse the public mind upon this (to them) important subject. I say important, for I have seen fields of Wheat, particularly along the hedge-rows, almost entirely destroyed for many feet in by these mis-called "farmers' friends." So much for our British farmers.

Now with regard to colonists. You say that the Governor of one of our colonies imported sparrows at a cost of £6 per dozen. I hope they were not the common house sparrow. Should any one wish to introduce birds into colonies—and many of our British birds would be very useful in destroying insects—they may easily tell which would be most suitable for this purpose by the beak; those that live upon insects have a much softer beak than those that live upon seeds. The seed birds have a hard, sharp-edged beak like that of the common sparrow, canary, or any of the finches, linnets, &c., none of which ever eat insects.—J. V.

[Your pages have for some time past contained many most able letters, *pro* and *con.*, regarding the cruelty or expediency of house-sparrow extirpation, in corn-growing districts especially; and, as truth alone is your object in all such practical discussions, I enclose this letter, which appeared in the *Standard*, and which I fully endorse, after many years' study of the habits of both the hedge and house sparrow genus. I have here scores of the former, and hundreds of the latter; the first enlivening my garden hedges and shrubberies with their cheerful notes, the last swarming in my evergreens and Ivy-matted walls and outbuildings! Indeed I have encouraged these colonies of merry chirpers, never allowing any to be killed, nor their nests to be taken, in the fond belief that I was harbouring an insectivorous bird in so doing! But alas! I must now record a verdict of graminivorous against my old pets, and, partial as I am to birds of all kinds, must fain condemn the house sparrow and tomtit as destructive to buds, grain, Peas, and bush-fruit.—AUDI ALTERAM PARTEM, *Aldwick, Sussex.*

P.S.—I hope you will find room for "J.V.'s." letter, were it only to plead the cause of that sweet songster, the hedge-sparrow, which, with the robin, cheers our sight and ear alike in this leafless season as they hop in our walks and flit in our hedgerows, melodious all the while!]

WORK FOR THE WEEK.

KITCHEN GARDEN.

As market-gardeners very generally sow their early crops upon sloping ground it would be advisable for others to adopt the same practice, by which, among other advantages, more heat and shelter are obtained. The slopes, of course, should run east and west, and are most convenient when about 3 feet 6 inches wide. They should, if possible, be close to the frame-ground, as many of the articles—viz., Radish, Early Horn Carrots, Lettuce, &c., will require occasional covering with litter, and frequent attention. Slopes of this kind, after carrying their spring and early summer crops, will be equally eligible for autumn ones, more especially

for Endive, autumn Carrots, or for raising the stock of winter Lettuces. *Asparagus*, the sooner the beds are manured and soiled the better. *Cauliflower*, sow a little seed, if not already done, in a box to be placed in a house at work. *Cabbage*, sow a small quantity of any early dwarf sort—the Vanack or Nonpareil—on a warm slope, also some white Spanish and Portugal Onions, and a pinch of Early Dutch Turnip. *Parsnips*, prepare ground by trenching or deep digging for sowing shortly. *Potatoes*, follow-up planting, at least the early kinds, soil them over 8 inches deep, and draw-off with the rake or hoe 2 or 3 inches in the early part of April as a clearing process. *Sea-kale*, plant; also Horseradish and Jerusalem Artichokes as soon as possible.

FLOWER GARDEN.

The season altogether has been most favourable for out-door improvements and alterations; but tender plants are in a very forward state, and, therefore, will require to be carefully protected from frosts. A small piece of ground would be useful as a reserve-garden for rearing evergreen shrubs—such as Laurels, Aucubas, Laurustinuses, Berberis, Rhododendrons, Box trees, &c.—which may be propagated at home or bought in from the nurserymen when a year or two old at a very trifling cost. They will come in very useful for filling-up beds or borders in winter, or for making improvements in the pleasure grounds. Many collections of Tulips are now so forward that unless protected in case of frost serious consequences would inevitably result to the embryo blooms, which, though below the surface, would be injuriously affected by it. *Ranunculus*-beds may be thrown-up in ridges of about 4 inches, taking care that the lower part of the bed remain undisturbed. By this means advantage can be taken of the first fine day for planting, should the weather prove fickle about the 14th of February; as when suffered to lie in that state the surface soil becomes sooner dry, and by simply raking level is immediately ready for putting in the roots. *Polyanthus* seeds may be now sown in pans. Some florists start them in a slight heat, and when up gradually harden them off. Look over and correct the general outlines of ornamental plantations. Break into all hedge-like lines, form bold recesses where space will admit of it, and endeavour to create variety. Biennials may be planted in flower-borders or beds. As there is no appearance of frost, Moss, Provence, and other hardy Roses may now be pruned; cut-out as much of the old wood as can be conveniently spared, and shorten-back young wood to the most prominent buds. The sooner that all Roses are planted now the better, except the more tender Chinese kinds. Roll gravel walks, sweep and clean as often as practicable. Weed Box, Gentian, and other edgings in mild weather.

FRUIT GARDEN.

Follow-up pruning and nailing. Thin orchard trees. Scrub off American blight with a hard brush. Clean off moss, lichen, &c. Make cuttings of choice Gooseberries, Currants, &c., taking care to pick out the buds at the lowest end of the shoot, in order to avoid suckers.

GREENHOUSE AND CONSERVATORY.

Keep up a mild and sweet atmosphere in the conservatory. If any plant is a prey to insects remove it immediately, to be thoroughly cleaned. Slightly increase the supply of water to the plants in the greenhouse. Keep down green fly. Give plenty of air, but beware of draughts. Cut down, number, and remove decayed Chrysanthemums; let them go dry in a cold pit. Cinerarias, if cramped in their pots, to be shifted into larger; likewise Chinese Primroses for spring work.

FORCING-PIT.

Introduce bulbs, Roses, Pinks, American shrubs, Lilacs, &c., in steady succession. Keep up a bottom heat of 75°, and an average surface temperature of 60° at night and 70° by day, with air occasionally.

PITS AND FRAMES.

The whole of the Verbenas, Petunias, Ageratums, Heliotropes, Salvias, and all the softwooded plants for planting-out in the flower-beds, except the Scarlet Pelargoniums, are best from spring propagation. Those in the store-pots may now be introduced into heat for that purpose; but many of them this mild season can be left till the first crop of cuttings is taken off, as they are in active growth. If the sorts are not scarce it is rather soon yet to begin with them, as they will require too much room before they can be planted-out in May. Auriculas to be top-dressed with two-year-old decayed hotbed manure and leaf soil. Poly-

anthuses grown in pots to be kept moderately moist, and a similar top-dressing, to that recommended for the Auricula, will be of great service to them.

W. KEANE.

DOINGS OF THE LAST WEEK.

GENERAL work much the same as the last week. Collecting leaves, wheeling dung and soil on crispy mornings, and when wet washing pots, cutting tallies, making stakes, and cutting-up one-year-old cut branches of spruce into twigs of different lengths for the flower-beds, thatching hurdles, making rough wooden portable boxes, &c.

In the KITCHEN GARDEN, took the opportunity of a dry day to stir the ground among Cabbages and Cauliflowers, and to put the earth close to Broccoli-stems. Stirred the soil among Radishes, Potatoes, &c.; put more Potatoes in shallow boxes to start, and will wait until the ground is more friable and dry before sowing Peas and Beans. We have had a long row of Parsley under protection, but as yet it has been little wanted, as the weather has been so mild, though unsettled. Several nights past, though mild at night, it was frosty before morning, and yet raining fast, and the thermometer at 40° by daybreak. At this season, therefore, it is scarcely safe to leave pits and frames uncovered, however mild the evening.

FRUIT GARDEN.

Sprinkled Vines and Peaches in the middle of the day, if at all warm or sunny, just to soften the buds. A few of the latter may be expected to drop, if much has been done to them in the washing and the dressing way; but that is often an advantage, rather than otherwise, as it saves thinning so much, and this, in general, we are too apt to neglect. Looked over Strawberries just moving. Keeping such plants extra damp now is very injurious, being very apt to cause the bud to split or rot at the centre. It is best, therefore, for the pots at present in houses to stand upon dry shelves, or on a little moss, and then there is less risk of over-watering. Plants that are forward and swelling will not hurt much, except as regards flavour; but those just moving, if allowed to stand in saucers with an inch of water in them, are almost sure to suffer from such treatment. It would be safer under such circumstances to turn the saucer over, and set the pot on the bottom of the saucer reversed. Pruned all sorts of trees, when the weather would permit, and moved some young Vines into an earth-pit, where there was a bed of leaves just a little hot, which bed, by-and-by, will come in for Potatoes.

CONSERVATORY.

Picked all signs of damp from the plants, and put a little fire on, especially during the day, to help to dissipate the damp, giving more air in proportion. As the weather is so uncertain, shut up pretty early in the afternoon. All watering is done the first thing after breakfast, and as little spilled on stage or path as possible.

STOVE.

Removed Begonias and Poinsettias out of bloom. Set Caladiums at rest—that is, their pots on sand to be kept moist, whilst no water is given to the pots, and fresh-arranged house, so as to make room for fine-leaved Begonias, Gloxinias, &c., before long. As this house averages only from 50° to 55°, and in cold nights is more near the former, a hand-light was placed over the Caladiums to keep them a little warmer. A few Gloxinias have also been placed in a vinery to start them slowly. Beneath the stage or platform in the small stove, the Genera zebra and others have been collected, to rest until wanted. Such plants as Cannas and Hedychiums, that did little good out of doors last year, are also packed in out-of-the-way places, where they will be safe from frost. The Pelargoniums in vinery were smoked twice, and the earliest are now seeking more room. Potting young plants was proceeded with as time and space could be obtained.

COLD PITS.

We hear that some were caught as well as ourselves by the sudden sharp frost of last week, but from the precautions used, nothing has suffered. Even the Verbenas that had a good amount of air all night, exhibit no trace of the visitation, but are luxuriant and healthy, and show that they are now relishing the repotting they had from 54's to 32's; the repotting, as you will recollect, being merely the transferring of a mass of plants—say three to the inch—from a small pot to a larger one. If Verbenas are not potted separately in the autumn, we would not

do it until March, unless we could give the pot bottom heat, and heat and air at top at will.

In a brick cold pit, we observe the Calceolarias, Salvias, &c., assuming a yellowish tinge, and we suppose we must let them wear it a little longer. This is entirely the result of dryness. Were we sure of such weather, we would water them, and give plenty of air, and they would soon be green enough, and too close together at too early a period; but if well watered now, and we should have a severe frost, they would then be more apt to suffer from being damp than they would be if dry. We do not expect such a frost; but it is as well to make sure, and, therefore, such plants will have little more water for a month to come than a skiff from the syringe in a sunny day, just to keep them from flagging.—R. F.

TO CORRESPONDENTS.

** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

BACK NUMBERS (S. R. T. B.).—We have received several copies of Nos. 50, 51, and 52, and shall be glad of more; but you and several others who have obligingly sent us copies have omitted to give your names and directions. We also want copies of No. 41.

GARDEN DRILL.—G. H. wishes to know where he can purchase one. We think those who make such horticultural implements would find it profitable to advertise them.

ICE-KEEPING (*An Eleven-years Subscriber*).—At page 14 we stated our own opinion upon your mode of ice-keeping, and at page 32 Mr. Beaton's. We shall be glad to know the result of your trial with no ventilation, and also of the experience of any of our readers who have tried ventilating against not ventilating an ice-house.

FRENCH CLOCKWORK FOUNTAINS (M. B.).—Our correspondent wishes to know where these, to be placed in a greenhouse, can be purchased.

MELON-CULTURE (*A. Rosling*).—We know of no separate work upon this subject; but if you refer to the indices of our last three volumes, you will find almost every point in Melon-culture discussed. Also in the last edition of our "Kitchen Gardening for the Many," you will find a good epitome of Melon-culture.

PRIMULA LEAVES DROOPING (*Subscriber, Lee*).—Bringing the plants from the moist air of a greenhouse to the intensely dry air of a sitting-room, will usually produce such flagging of the leaves. We introduce Primulas in a similar way, but we have either a glass shade over each pot, or plant the Primulas in a Bijou Plant Case. In neither mode of treatment do the leaves flag; and if you drop a single drop of gum water into the centre opening of each flower, it lasts longer in beauty.

FIELD MICE BARKING HOLLIES.—W. Hill will be glad of a hint as to the best way of getting rid of these pests. The woods and plantations are swarming with them. Quantities of Hollies, planted-out last April, are completely stripped of the bark from 2 to 3 feet high. Phosphorus poison has been tried, but this seems to have no effect. Poisoned grain would be dangerous on account of the Game.

GRUBS AT THE ROOT OF A FERN (*C. C., Stafford*).—The Fern is Asplenium viviparum. The grubs are the larvæ of Bibio Marci, a two-winged fly, which appears in great numbers in early spring. The grubs feed chiefly on decaying vegetable matter; but they also devour roots of plants, especially if not in good health. Lime water or gas tar water would doubtless dislodge them.—W. W.

SCOTCH FIR FENCE (*B. B.*).—We presume the line of trees you speak of, 5 or 6 feet high, has been planted either for shelter or ornament, as the Scotch Fir will be useless as a fence against cattle. Assuming it to be for one of the first-named purposes, and to consist of a single row of trees which are becoming naked at the bottom, we fear they have already stood too long untouched; but if they are still green at the bottom, thin them by taking away one-half of the number. If this is likely to make the place look naked, mark the trees you intend to remain, and cut away the lower branches of the others on the sides they touch and interfere with the permanent trees. This precaution ought to be taken in time, in order to retain the bottom branches as long as possible on the trees intended to make the future boundary; but this cannot have a permanent effect, as the natural habit of the tree to shed its lower branches will manifest itself in time; therefore, for a screen or fence under 12 feet high, we should have preferred Holly or Laurel, but as it is we would not advise you to clip the Scotch Firs. You may, however, top them if you do not want them hereafter for timber; but we would not advise more being cut-off than last year's shoots. If space and other circumstances allow of it, it would be better to plant a row of Laurel or Holly in front of the Firs, if the latter have lost their green branches at the bottom; for, unlike a deciduous tree, the Scotch Fir never regains its lower branches, and clipping only helps to destroy the green.

JARGONELLE PEAR TREE 2 OR 3 FEET FROM THE WALL (A. B. C.).—If your tree is healthy and vigorous, it might be very safely cut-down, so as to leave all the principal branches a foot long, or even less than that if you can find a smooth place, where we would advise the branch to be grafted. Even if you thought of continuing the same kind, it would be as well to put in some grafts in the ordinary way of crown-grafting, as the shoots from them could be made to point more in the direction they are wanted to grow, than if produced from the trunk of the tree. Other kinds might also be introduced at pleasure. April is soon enough for grafting in this way, but your scions ought to be in readiness before. Although few Pears excel the Jargonelle, we would, nevertheless, try some later kind, as Glou Morceau, Beurré d'Arenberg, Marie Louise, Vicar of Winkfield, and others. If the tree is very vigorous, it would be as well to root-prune it a little at the time it is cut-down; otherwise the superabundance of sap may seek for itself some other outlet than the limited one left for it. Your former letters, which you say were addressed to us on other subjects, have either not come to hand, or have been answered in a way in which you may have overlooked them.

YOUNG BRANCHES OF PEACH TREES DYING (L. G.).—The roots of the trees against the back wall of your orchard-house have either been kept too dry, or they have descended into an ungenial subsoil. If the latter supposition is the truth, you must cut away those roots, and by surface-manuring slightly, and mulching, induce the roots to keep more upwards. The tree which bore no fruit had sufficient sap to perfect its young wood; the trees well laden with fruit had not such sufficiency.

GLASS LABELS (W. F. S. A.).—Our correspondent wishes to know where glass labels for Rose trees are to be had. We make them for ourselves by making a glazier scratch with his diamond the names on strips of glass. In notches filed on the edges, wire may be fastened for attaching them to the trees.

PHYCELLA HERBERTI AND CYPELLA HERBERTI CULTURE (T.).—All the Phycellas, and all other bulbs from the same country, Chili, are very precarious when grown in pots. They do much better in raised borders under a south wall. Your dry bulb of Phycella Herberti ought now to be just pushing the points of the roots from the black bulb after having been at rest since last August. None of the Phycellas should ever have peat in pots, nor be watered after the end of August until February; and as they cast the old roots like Hyacinths, they are more safe out of the pots packed in sand in a box or drawer, and should be repotted early in February in good loam made light with sand, and the bulbs covered up to the neck with the soil. The greenhouse is too hot for them at the time of flowering, or after the leaves have finished their growth early in June, and it is in the excitement of overhear that causes them to go wrong, fail of flowering, and keep green out of season. A cold-pit treatment is best for them. *Cypella Herberti* ought to grow and bloom freely enough in a greenhouse in June and July if it had a winter's rest, and was in half peat and half loam the previous season; but many greenhouses are more for roasting plants in summer than helping them on. All such summer-growing bulbs do better in damp cold pits than in most greenhouses from April to October.

GLADIOLUSES IN POTS (A Cottage Gardener).—All that you and your friends have to do with your new purchases of Gladioluses, is to put them in No. 48-pots, one root in each, during the middle of February. Place the bulbs just within the soil, which should be as for Fuchsias, rather damp but not wet or dry, and do not water them, but put them out of sight somewhere, a cool cellar being the best place till the leaf is half an inch out of the ground; then a cold frame to the second week in May. Plant them then, where Cauliflowers would be likely to succeed well, in the garden, or if they are to be kept in pots repot them, and keep to the same first-class Fuchsia compost.

AMARYLLIS (Idem).—There are several kinds, and every kind requires a different treatment; but if we knew your sort we would aid you.

CLIMBER FOR A SHADED MOSS-HOUSE (W. H. B.).—As you did not mention the part of the country or of the three kingdoms where the moss-house is, all we can do is to answer as if it were on the shore of the Pentland Firth, to make sure of our selection being fit for the moss-house. And the best climber we know for a moss-house on the Pentland Firth is the Ruga Rose; it will cover it all over very soon, but not so thickly as to spoil the thatch. Gourds of all kinds are grown in the open air.

VARIEGATED MINT AS EDGING (Idem).—It will certainly make edgings not more than 4 inches high in one season in the strongest and richest land if it is treated properly, as we last season reported from the practice of Mr. Eyles at South Kensington, and also as we have often stated in these pages.

MOSSSES (Moss).—C is *Hypnum proliferum* of Linnaeus, and *Hypnum recubitum* of "English Botany." G is *Hypnum cupressiforme* of Linnaeus, and *nigroviride* of "English Botany." The "class of Mosses to which these belong," is that in which the theca is lateral—that is, the flower and fruitstalk come from the sides of the Moss plants, not from the top, or terminal, as in the Bog Moss or sphagnum.

CHRYSANTHEMUMS NOT BLOOMING (Idem).—The reason why your Chrysanthemums do not, or did not, open their flower-buds in the greenhouse is, that they were too late in forming the flower-buds. If you could introduce the plants to stove heat, and give them as much as 60° at night, and plenty of water, every one of them would open. We have seen such a thing forty years ago.

YELLOW-BERRIED HOLLY (Idem).—It is not very common, although there is no reason why it should be scarce. There is only one way of propagating it; bud or graft it on stocks of the common Holly.

GLASS EFFRONES (Patekin).—We have had no experience of these, and cannot advise.

PUTTING LAPS IN A GREENHOUSE (Idem).—We would putty all laps, and give air otherwise.

MELON-HOUSE (A Real Greenhorn).—We approve of the whole of the arrangements. We would only make one suggestion. In the bed, make a layer of concrete, smooth on the surface, below the pipes; and then, by a drain-tile, you can pass water among and through the rubble, and thus have moist bottom heat whenever you like. The same would be effected by having 6 inches of rubble above the pipes, 2 or 3 inches of concrete, then 3 or 4 inches of rubble drainage, and then the soil. The first mode would be the more simple.

FOILAGE PLANTS FOR A BED (A Young Sub., Herts).—You say that your "lady employer is desirous of having a bed entirely of foliage plants in the flower garden next summer;" and instead of, for your own improvement, making out a list of the best foliage-plants for beds which you have read about for the last three years, or have seen or heard of otherwise, you ask us to do so for you. You must also have read in this Journal that we do not supply lists to plant any particular bed; all that is proper for us is to criticize the lists for planting which our subscribers send up to us for that purpose. All young gardeners ought to have known that long ago. Make use of your own judgment, and we will criticize your selection and plan if you send them to us.

CAMELLIA LEAVES SPOTTED (J. E.).—The spots are occasioned by the roots being kept too wet or too dry. There is deficient root-action from some cause which we can only guess at. Probably the centre of the ball of earth is hard and dry. The Fern you enclosed is *Cyrtomium falcatum*.

USE OF A VACANT PIT (A. E. F.).—We cannot afford either time or space to answer all your queries. Fine-foliaged Begonias may now be moved to the forcing-pit, and kept rather dry even there until the fresh leaves begin to come, when they should have most of the old soil shaken from them, be repotted, and kept close and warm until growth commences. You may place there cuttings of any Fuchsias. The young plants in the greenhouse, if wanted large, would stand more than greenhouse heat. The large plants, now dry and leafless, should have a little water. The same may be said of cuttings of all kinds of Geraniums, Petunias, Cobæas, Plumbagos. They will stand from 55° to 65° at night, but must have more air as soon as struck. The Stephanotis we presume is in the forcing-pit, as unless your greenhouse is kept warm it would not be healthy there; and the cuttings of that will stand from 5° to 15° more heat after it is struck than the Geraniums and Fuchsias. The coolest part of such a pit would do to strike cuttings of Phloxes; but the cuttings will be best obtained a couple of months or so after this, when the young shoots are some 2 or 3 inches in length. You may sow any perennial greenhouse seeds, whether herbaceous plants or shrubs, and by potting them off early, they will make nice little plants before winter. Of seeds of annual plants for the greenhouse we should scarcely sow any now, except the different sorts of Cockscombs. All other annuals would be tender and drawn. For planting out of doors, we would confine annual-sowing now chiefly to Intermediate and Ten-week Stocks; and these, as soon as fairly up, would need to be moved to a cooler place. The same may be said of all sorts of Pansies, and the new Chinese Pinks.

CUCUMBER-PIT (A. H.).—The simplest plan against your south wall would be a pit above the ground level—say 6 feet wide, front wall 2 feet in height, plate for rafters on wall 4 feet in height; flue, single or return, in centre; platform across, with means for letting the heat up; sashes made to slide, and entrance obtained by moving sashes. The following would be a little more expensive but much superior, making a house instead of a pit:—Front wall 2 feet high, with ventilators in it; width, 8 feet; back wall, 8 or 9 feet; roof fixed; sash-bars 3 inches, to receive glass 18 inches wide by 12; trellis, 15 inches from glass; wood ventilator hinged at top, 9 inches wide; flue, 2 feet from front, and pots placed over flue.

WHITE AND BROWN SCALE ON FERNS (Ignoramus).—Try dipping the Ferns in size or gum water, just strong enough to be a little sticky between the thumb and finger. Keep the plants in a shaded place for a day or two, and then dip them and gently move them about through clear water at about 120°. If very bad, it will be best to let the fronds ripen by curtailing water, and then cut-down freely and start afresh—that is, if the kinds will admit of that treatment. Such plants could then be washed at the base of the stems, and a fresh potting given them, so as to remove a portion of the old soil, and fresh growth encouraged.

CUCUMBERS AND MELONS IN A HEATED GREENHOUSE (A Constant Subscriber, Britonferry).—We would advise training the plants up the front and top of the wall, and then 18 inches from the glass roof, putting the pots of Melons in front and the Cucumbers at the back. We would have entered more fully into your case, but cannot give you more definite directions than you will find at page 24; only, when you have good strong stems of Cucumbers, you must stop them often, as you want a continuous supply, whilst the Melons will only ripen one crop.

GERMAN IVY (J. H.).—You will find all we know about it at page 795 of our last volume. Any of the large nurserymen who advertise in our columns could procure it, if they do not happen to have it. The cocoa-nut-fibre dust was advertised in our last Number by Messrs. Barsham, Kingston-on-Thames.

MARIE LOUISE PEAR UNFRUITFUL (Tyro).—If you cut it down as you propose, you will only have, as its successor, a wild Pear or whatever kind it was grafted on. You had better shorten the branches and graft on the stumps, as recommended in the present Number to the owner of another barren Pear tree.

GRAPES RIPE BY AUGUST (Y. Z.).—To have Grapes ready for the 1st of August, you will not be too soon if you begin to break the Vines very quietly at once, and the Grapes will be none the worse if ripe a few days earlier, though a fortnight or even three weeks later would do.

PLUNGING MATERIAL FOR A PIT (An Irish Subscriber).—The best material is just according to circumstances. If your pots stand near the bricks and tiles, cocoa-nut fibre will do well to pack among your pots, because it will keep the heat about them, from its nonconducting property. If you placed your cocoa-nut fibre a foot thick over your rubble, and then set or plunged small pots on it, you would obtain little bottom heat from the same cause, so long as the fibre next the rubble was dry. If damp all through, and water placed in contact with the pipes, your fibre would then absorb and conduct heat. Where nice growth is desired, we should prefer sweet tan to any fibre, though we have not tried the latter for the purpose. For neatness, we would as soon have sand as anything. It is easily moistened. We recommend the "Fruit Manual" for descriptions, and the "Florist and Pomologist" for coloured representations of the best fruit. There is no modern work on fruits with coloured drawings of them exclusively.

A BELT OF TREES ON CLAY SOIL (An Old Subscriber).—On a strip of cold, heavy, damp land that has been in fallow for the last five years, after a crop of Scotch Fir, Yew, and Elm, we would not plant any of the Fir tribe now, but Elm would do quite as well as before. For country work the wood of the Black Italian Poplar and that of the Huntingdon Poplar come soonest to hand, and pay best; and they and the Elms are just the right kind of timber for such a strip of land.

CLIMBER NOT BLOOMING (J. C.).—It is *Jasminum campanulatum*—a very old stove plant that will never thrive in a greenhouse.

VARIOUS (H. A. Doyne).—You will see about *Gladioluses* in pots in an answer to-day to another correspondent. Plant your Ashleaved Kidney Potatoes at the beginning of March in light rich soil in a sheltered situation. You may safely nip off the tops of the over-tall *Verbena* cuttings.

ORCHARD-HOUSE (Novice).—We see nothing against your system answering, except your ventilation. The 18 inches all the way along the front will do; but if you have no more than the two end lights at top, of 36 by 20 inches, then we also judge that the Vines, and more especially the Peaches and Apricots, will be eaten up by red spider. Have a ventilator at the apex equal to 10 or 12 inches all the way, and you may do, or as is represented in Pearson on "Orchard-Houses," page 43. The bush Vines would be as well not to be more than from 5 to 6 feet.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

HYBRID BETWEEN PHEASANT AND FOWL.

As this subject has attracted notice in our columns of late, we are anxious to give our own experiences in the matter. We had seven hybrids that were the produce of one hen. A tame cock Pheasant had been brought up in the yard with the fowls, and chose as his mate a chicken of his own age, a rather small Brown Dorking hen. They never, either of them, consorted with or took any notice of the other fowls, but constantly wandered away together. They lived in a rick-yard principally. It was bounded by that which is now becoming a scarce sight—a hedgerow. The hen stole her nest there and brought out her chickens.

It has often been said that spangled fowls, whether Malays, Polands, or Hamburgs, derive their spangled breasts from some mixture of Pheasant blood. Nothing can be more erroneous. The produce of these birds was neither Pheasant nor fowl, yet so plainly a mixture of both that no one could be deceived as to its origin. It was decidedly a hybrid incapable of breeding, yet there was sufficient difference of size and even of appearance to cause every one to call the birds cocks and hens. They were so only in name. Not one had the comb of the fowl, nor the rich red face of the Pheasant. The so-called hens took interest in nothing. The cocks would watch the fowls all over the place for the pleasure of sitting on the eggs, and we have often regretted since that we did not, as an experiment, allow one of them a few eggs. We have since seen so many curious mothers (?) that we have no doubt these would have done very well. We will attempt to describe them. The largest and finest bird was brown-bodied, with black hackle and saddle, large pheasant-shaped body; head, eye, and carriage belonged to the Pheasant; beak, five claws, and tail, although long, made up of ten straight feathers, belonged to the hen. Some of the smaller birds, called hens, evidently threw back to the hen's forefathers, as they had most unmistakable Dorking plumage. None had fowls' tails. Most of them had five claws; several were speckled brown and white, but there was not a pure Pheasant's feather, a spangle, or a lacing among them. Some had the dark head and neck of the cock Pheasant, but no approach to the colour, gloss, or brilliancy of these, nor were they composed of the same small feathers. They were tame spiritless things. After the novelty had worn off they were hardly interesting, and we gave them away.

Some time afterwards we were offered another, which our friend said was bred between a cock Pheasant and a Spanish hen. We had our doubts, but the first sight dispelled them. It was the finest bird of the sort we have ever seen, thoroughly black all over, with the glossy tint of the fowl; but having the head, tail, shape, and carriage of the Pheasant. We should have liked to have kept this one, but it was so spiteful we were obliged to kill it; no bird could live with it. This, again, had neither comb nor red eye.

In every instance that we have known, and we believe in all other cases, the cross has been between the cock Pheasant and common hen; we have never known a fowl take to a hen Pheasant. It is also absolutely necessary that the Pheasant should not only be a tame-bred bird, but that he should be brought up with the hens he is intended to breed with. With every help, knowledge, and contrivance crossing is seldom accomplished. Crosses are almost unknown where birds are in a state of nature, and those that have occurred have generally been among escaped tame birds in the neighbourhood of keepers' houses.

We have never met with a cross between a Partridge and any other bird.

MANCHESTER POULTRY SHOW.

FROM accidental causes I am only this day (January 17th) in receipt of your Journal of the 6th inst., where I observe at page 16, when commenting on the above Show, the Judges are accused of making a mistake in Class 65. Of course all persons must know the very difficult and unsatisfactory position a poultry judge occupies at the present day, and a "mistake" is very possible, as it may arise from several causes; but with regard to the pen of fowls in question (presuming it as implied that the first and second prize pens should exchange place), writing from memory, if a straw-coloured hackle, with brassy feathers in the wings of a Silver-pencilled Hamburg cock are points of excellence I allow the Judges are wrong in their decision; but if otherwise, maintain our award to be right.—WM. LLOYD.

POULTRY CLUB.

A MEETING, in connection with the Poultry Club, was held at Liverpool on Wednesday, 21st inst., Mr. Stretch in the chair, the following gentlemen being present:—Messrs. Teebay, James Munn, Tudman, Eden, Douglas, T. H. Ashton, Kelleway, E. Smith, Glendinning, Ashcroft, Hyde, Wood, Walthew, Capt. Heaton, &c.

It was proposed by Capt. Heaton, and seconded by Mr. Wood, "That a Poultry Club be established."

Proposed by Mr. Munn, and seconded by Mr. Kelleway, "That the yearly subscription be 10s. 6d."

Proposed by Mr. Wood, and seconded by Mr. Munn, "That Mr. Tudman, Ash Grove, Whitechurch, Salop, and Mr. H. Ashton, 4, The Terrace, Richmond Hill, London, S. W., be the Honorary Secretaries."

Proposed by Mr. Kelleway, and seconded by Mr. S. H. Hyde, "That the next General Meeting be held at Worcester, at the time of the Agricultural and Poultry Shows."

The following gentlemen were elected Stewards for 1863:—Mr. T. Stretch, Capt. Heaton, Mr. J. Hindson, Mr. T. H. D. Bayley, Mr. James Munn, Mr. R. Teebay, Mr. T. P. Wood, jun., Mr. Kelleway, Mr. W. H. Berwick, Mr. Peter Eden, Mr. S. H. Hyde, Mr. James Douglas.

All persons desirous of becoming Members of the Club are requested to communicate with Mr. Tudman, who will receive their subscriptions.

LIVERPOOL POULTRY EXHIBITION.

THIS was held on the 21st and 22nd inst. There were about 370 pens of Poultry and 100 of Pigeons.

JUDGES.—For Hamburgs, Game, and Game Bantams, Mr. R. Teebay. For other varieties, Mr. G. Fell, of Warrington. For Pigeons, Mr. Harrison Weir. The following were their awards:—

SPANISH.—Silver Cup, R. Teebay. Second, H. Lane. Third, J. K. Fowler. Highly Commended, J. R. Rodbard; W. Brundrit.

DORKINGS (Coloured).—Silver Cup, Viscountess Holmesdale. Second, Capt. Hornby. Third, C. H. Wakefield. Highly Commended, A. Potts; Viscountess Holmesdale; Capt. Hornby; W. T. Everard; Rev. J. F. Newton E. Tudman.

DORKINGS (Silver-Gray).—First, E. Musgrove. Second and Third, G. Cargey. Highly Commended, T. Statter.

COCHIN-CHINA (Buff and Cinnamon).—Silver Cup, C. Felton. Second, Mrs. H. Fookes. Third, E. Musgrove. Highly Commended, T. Stretch; H. Bates; Mrs. H. Fookes; J. W. Kelleway; R. E. Ashton.

COCHIN-CHINA (Partridge and Grouse).—First, Capt. Heaton. Second, J. Shortrose. Third, T. Stretch. Highly Commended, C. Felton; C. H. Wakefield; E. Musgrove.

BRAMA FOOTRA.—First and Second, R. Teebay. Highly Commended, H. Lacy.

GAME (Black-breasted Red).—Silver Cup, J. Hindson. Second, M. Billing, jun. Third, Mrs. Hay. Highly Commended, J. Fletcher.

GAME (Brown Red).—First, J. Fletcher. Second, Rev. F. Watson. Third, T. Statter. Highly Commended, J. P. Smith; T. West; J. Wood.

GAME (Duckwing and other Greys).—First, J. Hindson. Second, F. Worrall. Third, J. Foden. Highly Commended, G. Hellewell.

GAME (Other varieties).—First, T. West. Second, A. Guy. Highly Commended, W. Dawson.

HAMBURGHS (Golden-pencilled).—Silver Cup, J. Munn. Second, J. E. Powers. Third, Rev. T. L. Fellowes. Highly Commended, C. W. Brierly. Commended, J. Munn; W. Kershaw.

HAMBURGHS (Silver-pencilled).—First, J. Robinson. Second, S. Shaw. Third, D. Harding. Highly Commended, C. Moore; J. E. Powers; D. Harding; S. Shaw.

HAMBURGHS (Golden-spangled).—First, W. Cannan. Second, H. W. B. Berwick. Third, S. H. Hyde. Highly Commended, N. Marlor. Commended, H. Carter.

HAMBURGHS (Silver-spangled).—First, W. Cannan. Second and Third,

J. Fielding. Highly Commended, J. Robinson; R. Bell; Commended, S. Shaw.

POLANDS (Any variety).—First, H. Carter. Second, R. P. Williams. Highly Commended, Miss E. Beldon.

BANTAMS (Black and Brown Red Game).—Silver Cup, J. W. Kelleway. Second, J. Camm. Third, T. H. D. Bayly. Highly Commended, T. H. D. Bayly; E. Yardley; M. Turner; J. Camm; W. S. Forrest.

BANTAMS (Duckwings and other Game varieties).—First, W. Silvester. Second, R. Horsfall, jun. Third, W. Lawrenson. Highly Commended, T. Davies; J. Camm.

BANTAMS (Other varieties).—First, T. H. D. Bayly. Second, M. Leno, jun. Highly Commended, J. Mangnall.

DUCKS (Rouen).—First, J. Munn. Second, R. E. Ashton. Third, S. Shaw. Highly Commended, E. Longton; T. Robinson; R. E. Ashton. Commended, J. Foden; T. Statter.

DUCKS (Aylesbury).—First, T. E. Kell. Second, J. K. Fowler. Third, Mrs. T. W. Hill.

DUCKS (Other varieties).—First, T. H. D. Bayly. Second, F. W. Earle.

COCHIN-CHINA CHICKENS (Buff and Cinnamon).—Cup, A. F. Watkin. Second, J. W. Kelleway. Third, T. Stretch. Highly Commended, T. Stretch; H. Tomlinson; Rev. G. Gilbert; Mrs. H. Fookes; J. W. Kelleway.

COCHIN-CHINA CHICKENS (Partridge and Grouse).—First, T. Stretch. Second, E. Musgrove. Third, R. White. Highly Commended, E. Musgrove. Commended, T. Stretch.

SINGLE COCKS.

COCHIN-CHINA (Buff and Cinnamon).—First, Mrs. H. Fookes. Second, E. Smith. Third, H. Chavasse. Highly Commended, T. Stretch; E. Musgrove; H. Bates. Commended, J. T. Lawrence; T. Boucher.

COCHIN-CHINA (Partridge and Grouse).—First, E. Musgrove. Highly Commended, Capt. Meaton.

DORKING (Any variety).—First and Second, Viscountess Holmesdale. Highly Commended, T. Statter; J. D. Hewson.

SPANISH.—First, J. Potter. Second, T. P. Wood, jun. Highly Commended, R. Teebay; W. W. Brundrit.

HAMBURGH (Golden-pencilled).—Prize, J. Munn.

HAMBURGH (Silver-pencilled).—Prize, D. Harding.

HAMBURGH (Golden-spangled).—Prize, J. Mellor. Highly Commended, W. Kershaw; J. Davies; W. Worrall.

HAMBURGH (Silver-spangled).—Prize, J. Fielding.

GAME BANTAMS (Black and Brown Reds).—First, J. W. Kelleway. Second, E. Musgrove. Third, T. Moss. Fourth, T. H. D. Bayly. Highly Commended, E. Yardley.

GAME BANTAMS (Other varieties).—First, C. W. Brierly. Second, W. O. Kenyon. Highly Commended, J. Munn; W. Lawrenson.

SWEEPSTAKES.

GAME COCKS.—First, F. Fletcher. Second, J. Hindson. Third, T. Statter. Fourth, J. Stubbs. Fifth, J. S. Butler. Highly Commended, T. Robinson; R. Swift; T. P. Wood, jun.; G. Cargay.

Cockerels.—First, M. Billing, jun. Second, S. Mathew. Third, J. Hudson. Fourth and Highly Commended, J. Fletcher. Fifth, J. S. Butler. Commended, M. Billing, jun.; J. Wood; S. Mathew; N. Grimshaw; C. Kellock.

PIGEONS.

CARRIERS.—First and Second, P. Eden. Commended, A. L. Silvester.

ALMOND TUMBLERS.—First and Highly Commended, F. Else. Second, P. Eden.

SHORT-PAKED TUMBLERS (Any other variety).—First, P. Eden. Second, E. T. Archer. Commended, F. Esquilant.

POWTERS.—First, R. Fulton. Second, S. Robson. Highly Commended, P. Eden. Commended, T. H. Evans.

JACOBS.—First, Highly Commended, and Commended, J. T. Lawrence. Second, F. Esquilant.

TURBITS.—First, S. Shaw. Second, A. L. Silvester. Highly Commended, J. T. Lawrence; S. Shaw.

BABES.—First, P. Eden. Second, J. T. Lawrence. Highly Commended, S. Shaw; J. T. Lawrence. Commended, T. D. Walker.

OWLS.—First and Second, F. Else. Highly Commended, A. L. Silvester. Commended, H. Morris.

FANTAILS.—First, J. W. Edge. Second and Highly Commended, F. Else. Highly Commended, D. Thwaite. Commended, J. R. Bailly, jun.

TRUMPETERS.—First, S. Shaw. Second, W. H. C. Oats. Highly Commended, J. R. Bailly, jun. Commended, S. Robson.

ANY OTHER BREED.—First and Third, S. Shaw. Second, A. L. Silvester. Fourth, F. Esquilant. Highly Commended, A. P. Leite; A. S. Bretherton. Commended, H. Yardley.

THE GREAT FRENCH POULTRY FARM.

WITH care and good management, no branch of domestic industry is more profitable than rearing poultry. Many persons have supposed that what is profitable on a small scale might be made still more so when carried on to a larger extent, but repeated experiments in this and other countries have proved this to be a mistake. The secret of the matter is, that hens cannot thrive and lay without a considerable quantity of animal food. Where but a limited number of fowls are kept about the farmyard, the natural supply of insects is sufficient to meet this demand; and hence, when attempts have been made to extend the business beyond this source of supply, they have not prospered. It will be seen from the following interesting account, that M. de Sora, of France, has adopted a method that has proved completely successful, by affording an artificial supply of this essential portion of food.

The French practical philosophers certainly know how to make the most of things. A M. de Sora has recently discovered the secret of making hens lay every day in the year by feeding them on horseflesh. The fact that hens do not lay eggs in winter as

well as in summer is well known, and the simple reason appears to be that they do not get the supply of meat which they obtain in the warm season from worms and insects. M. de Sora was aware of all these facts, and living at the time upon an old, delapidated estate a few miles from Paris, the acres having been bequeathed to him a few years previously, he set himself earnestly at the task of constructing a henary which should be productive twelve months in the year. He soon ascertained that a certain quantity of raw mince-meat, given regularly with other food, produced the desired result; and commencing with only some 300 female fowls, he found that they averaged the first year, some twenty-five dozen eggs in the 365 days. The past season he has wintered, thus far, about 100,000 hens, and a fair proportion of male birds, with a close approximation to the same results. During the spring, summer, and autumn they have the range of the estate, but always under surveillance. In winter their apartments are kept at an agreeable temperature; and although they have mince-meat rations the year round, yet the quantity is much increased during the cold weather. They have free access to pure water, gravel, and sand, and their combs are always red. To supply this great consumption of meat, M. de Sora has availed himself of the superannuated and damaged horses which can always be gathered from the stables of Paris and the suburbs. The useless horses are taken to an *abattoir* owned by M. de Sora himself, and there neatly and scientifically slaughtered. The blood is saved clean and unmixed with offal; it is sold for purposes of the arts at a remunerative price. The skin goes to the tanner; the head, hoofs, shanks, &c., to the glue-maker and Prussian blue manufacturer; the large bones make a cheap substitute for ivory with the button-maker, while the remainder of the osseous structure is manufactured into ivory black, or used in the shape of bone-dust for agricultural purposes. Even the marrow is preserved; and much of the fashionable and highly perfumed lip-salve and pomade was once enclosed in the leg bones of old horses. Uses are also found for the entrails, and, in fact, no portion of the beast is wasted.

The flesh is carefully dissected off the frame, of course, and being cut into suitable proportions, it is run through a series of revolving knives, the apparatus being similar to a sausage machine of immense size, and is delivered in the shape of a homogeneous mass of mince-meat, highly seasoned, into casks, which are instantly headed-up, and conveyed per railroad to the egg-plantation of M. de Sora.

The consumption of horses for this purpose by M. de Sora has been at the average rate of twenty-two per day for the last twelve months, and so perfectly economical and extensive are all his arrangements, that he is enabled to make a profit on the cost of the animals by the sale of the extraneous substances enumerated above—thus furnishing to himself the mince-meat for much less than nothing, delivered at his henary. It has been ascertained that a slight addition of salt and ground pepper to the mass is beneficial to the fowls; yet M. de Sora does not depend upon these conditions alone to prevent putrefaction, but has his store-rooms so contrived as to be kept at a temperature just removed from the freezing-point through the year, so that the mince-meat never becomes sour or offensive; the fowls eat it with avidity; they are ever in good condition, and they lay an egg almost daily in all weathers and in all seasons. The sheds, offices, and other buildings are built around a quadrangle, enclosing about twenty acres, the general feeding-ground. This latter is subdivided by fences of open paling, so that only a limited number of fowls are allowed to herd together, and these are ranged into different apartments, according to their age, no bird being allowed to exceed the duration of four years of life. At the end of the fourth year they are placed in the fattening-coops for about three weeks, fed entirely on crushed grain, and then sent alive to the city of Paris.

As one item alone in this immense business, it may be mentioned that in the months of September, October, and November last, M. de Sora sent nearly 1000 dozens of capons to the metropolis. He never allows a hen to sit. The breeding-rooms are warmed by steam, and the heat is kept up with remarkable uniformity to that evolved by the female fowl during the process of incubation, which is known to mark higher on the thermometer than at any other period. A series of shelves, one above the other, form the nests, while blankets are spread over the eggs to exclude any accidental light. The hatched chicks are removed to the nursery every morning, and fresh eggs laid in to supply the place of empty shells. A constant succession of chickens is thus insured, and, moreover, the feathers are free from

vermin—indeed a lousy fowl is unknown on the premises. M. de Sora permits the males and female to mingle freely at all seasons, and after a fair trial of all the various breeds, has cleared his establishment of every Shanghai, Cochinchina, or other outlandish fowl, breeding only from old-fashioned barnyard chanticleers, and the feminines of the same species. He contends that the extra size of the body and eggs pertaining to these foreign breeds can only be produced and sustained by extra food, while for capon-raising the flesh is neither so delicate nor juicy as that of the native breed. The manure produced in this French establishment is no small item, and since it forms the very best fertiliser for many descriptions of plants, it is eagerly sought for at very high prices by the market-gardeners in the vicinity. The proprietor estimates the yield of this year at about 100 cords. He employs nearly 100 persons in different departments, three-fourths of whom, however, are females. The sale of eggs during the past winter has averaged about 40,000 dozen per week, at the rate of six dozen for four francs, bringing the actual sales up to 250,000 dols. per annum. The expenses of M. de Sora's hennery, including wages, interest, and a fair margin for repairs &c., are nearly 75,000 dols., leaving a balance in his favour of 175,000 dols. per year.—(*Scottish Farmer*.)

MULE BIRDS.

Will the undernoted crosses give beautiful-plumaged birds?—Goldfinch and Bullfinch, Chaffinch and Buff Canary, Chaffinch and Yellow Canary, Goldfinch and Yellow Canary, and Goldfinch and Buff Canary. Should a Bullfinch cock and Goldfinch hen be put together, or the reverse, and so of the others? What is the best way to proceed? Should they be wild or tame, and kept in the house or outside?—T. S.

[The crosses mentioned will give beautiful-plumaged birds, with the exception of the Chaffinch and Buff Canary, which would throw out dull colours. In each case the Goldfinch and Chaffinch should be the male bird, and should be tame; if possible, brought up from the nest. The birds would do best in the house; and, provided they are to be turned into an aviary, they must be well paired previously. But we would recommend that they be put in separate breeding-cages.]

DESERTION OF HIVES, AND ITS CAUSES.

I HAVE perused with much pleasure Mr. Lowe's interesting article on bees deserting their hives, and can confirm his observation of the fact that when colonies of the Italians and the common species are in close proximity, a certain degree of intermingling is the result. I am disposed to attribute this circumstance to individual bees mistaking their hives, and either by eluding or bribing the sentinels, obtaining a recognised status in the colony to which they have in the first place accidentally introduced themselves. With regard, however, to the common stock in which 20 per cent. of the Italian race were discovered, we must I think attribute the intermixture to a far different cause. I shall indeed be surprised if desertion have anything to do with it, and have little doubt that it is really a case of hybridisation, the black queen having been impregnated by a Ligurian drone, and a mixed progeny being the natural result.

I had myself an amusing case of desertion this autumn. A second swarm with a few combs and about a couple of ounces of honey having been presented to me, I transferred the bees from their straw hive into a box partially furnished with combs. Although they appeared at the time to acquiesce in the change, they resented the interference by quitting their new domicile a few hours afterwards, and my garden accordingly presented the unwonted spectacle of bees swarming late in October. The queen having probably dropped from weakness in some obscure corner, the bees refused to cluster, and it was not until I had presented them with two other queens that they adopted one and permitted me to hive them—a woefully diminished cluster—in the box which they had quitted in dudgeon a couple of hours previously. The loss of the queen was otherwise of little importance, since deposed sovereigns were at that time nearly as plentiful with me as they were on the Continent in the memorable year 1848.

The tendency to fraternise with strangers which is occasionally manifested by bees relieved me from a difficulty last summer. A very strong stock sent from a distance reached me in a most

deplorable condition. Owing to want of ventilation, resulting from bad packing, every comb was smashed, multitudes of the bees were dead, and the remainder in a most lamentable state—few, indeed, being able to use their wings. Utterly at a loss what to do with the survivors, I opened the hive in my garden, luckily in the immediate neighbourhood of a small box containing a queen and a few hundred bees. In one minute the difficulty was solved. The few bees that could fly betook themselves at once to this little community, and stood with vibrating wings on the alighting-board. This hint was enough. I propped the chaotic hive in front of the small colony, and a living stream forthwith resulted, which had the doubly beneficial effect of strengthening the community to which they migrated and preserving themselves from destruction.

I am glad to learn that Mr. Lowe is about to investigate for himself the wonderful phenomenon of parthenogenesis in the honey bee, and shall be happy to assist him by every means in my power. Although he declares that several might be urged, I am not myself aware of a single loophole that has not already been most thoroughly explored and effectually stopped. Having, I believe, investigated this subject more thoroughly than any other Englishman, I may be permitted to indorse the conclusion of Dzierzon, who declared so recently as March last, "To me at least is this proof a strictly mathematical one, and so convinced am I of the truth of parthenogenesis in bees—namely, in drone-production—that, to speak like Brüning, I would lay down my life for this conviction."—A DEVONSHIRE BEE-KEEPER.

FEEDING IMPRISONED BEES.

I HAVE put rather a weak stock of bees into a chamber, and am feeding them with the "inverted bottle" at the top. The hive, which is one of Neighbour's, is shut up close, so that the bees are confined, except that they have access to a glass bell on the top. At times in warmer weather, when the glass in the hive is at 60° or higher, they seem to grow very angry, and swarm into the bell. Will this close confinement hurt or smother the bees, and when will be the best time to put the hive out of doors again? I have known a hive of bees tied up in a sheet and hung up in a room all the winter. Why are mine so restless?—B. B.

[We do not wonder at your bees becoming "very angry" under such circumstances. Feeding bees whilst in confinement is most injurious to them, and we should not be surprised to learn that yours are dead ere this. If they still survive, by all means give them their liberty without delay, and if feeding be imperatively necessary, keep a full bottle at the top of the hive. You will find they will appropriate its contents during mild days, and leave them untouched in cold weather.]

PROFITLESS BEES.

It is now many years since I began to keep bees, and I remember a very respectable seedsman telling me I could keep bees if I would feed them, but they would not keep themselves. I have kept them on the old plan in skeps on the Podolian plan, and these last four years on Payne's plan as in your "Bee-book for the Many." My bees are always so light in autumn, that I have to do as the seedsman said—feed them. I never saw stronger colonies than I always have, nor can any be healthier. They are not infested with insects or other enemies, and I seriously tell you I have spent upwards of £20 on bees, and during the course of my bee-keeping never had one ounce of honey from my bees. I never could induce any one hive to adopt either a glass or wood super. I keep them in a roomy beehouse of wood, where they are always quite dry, with a south-east aspect; they never fight or attack each other; the house will hold two rows of four one above another. I am quite in the country—all green fields and gardens around, with no manufactories of any kind for a mile and half. I feed them in the autumn with syrup, and in the spring with barleysugar. They are always strong, numerous, courageous, and healthy.

Can you tell me a plan to manage them so that I can treat my wife as the German Albert Braun, and how best to work them so as to keep always and only three hives through the winter? If so, you will greatly oblige, as I am now becoming tired of so profitless a pursuit.—T.

[Many amusing and edifying bee-stories have unquestionably appeared in our columns during the past four years, but none

appear to us so astounding as your own. Your ill-success must, we should think, be attributable to an indifferent honey locality, supplemented probably by some mistakes in management. Where you may have erred we find it impossible to say, but as the main object of bee-keeping is undoubtedly the procuring a return in the shape of honey, we should recommend you to go back to first principles, and, abandoning for the time all attempts at supering, &c., try the old-fashioned swarming system. From three strong stocks you may reasonably expect from four to six or even more swarms during the summer. A little trouble in weighing will tell you when these are at their heaviest (probably in August), then expel their inhabitants by driving, and apportion them amongst your three old stocks as recommended in pages 45 and 46 of "Bee-keeping for the Many." You will thus be able to treat your wife to some beautiful honeycomb, and contemplate with equanimity any trifling outlay for sugar (supposing it to be required) to provision your old stocks during winter. Any empty comb should be carefully preserved, and if inserted in your supers and glasses the following spring, will most probably overcome the reluctance which your bees have hitherto evinced to work in them. By thus going back, as it were, to rudimentary bee-keeping, and feeling your way upwards and onwards step by step, we have little doubt of your ultimately overcoming all difficulties, and even rivalling those amongst our correspondents who are able to exhibit their forty or fifty-pound supers of pure honeycomb.]

BEEES IN BUILDINGS.

I HAVE had but little experience with regard to keeping bees in buildings, but that little rather induces me to form an opinion adverse to the adoption of the plan of sheltering hives.

In the autumn of 1859, a large globe-hive was brought in from the country, and placed in an unused drawing-room, the bees working out through a slit under the window-frame about 20 feet from the ground. Here the bees remained the winter, no fire ever being lighted. In the spring they commenced breeding and working early, and showed symptoms of increasing population, as soon as any of my other stocks out of doors. But when the cold winds of March and April came, the ground and areas in front of the whole row of houses were daily thickly strewn with dying bees, so much so that my neighbours complained of them as a nuisance. Partly owing to their remonstrances, but chiefly to save the lives of the bees that were left, I removed the hive to the country, where it quickly regained its strength, and in June sent out a very fine swarm.

I have tried a hive in a greenhouse, but it never thrived satisfactorily. The house was elevated considerably above the ground, and I am inclined to think that this is one cause of failure. At the same time, I have known gentlemen, enthusiasts on the subject of bees, who have built costly structures of brick for their favourites, but they have not thriven in them. The reason why is by no means apparent, as every care seemed taken to insure success.

Bees will, however, sometimes thrive in holes in walls, or under roofs and ceilings of their own seeking. Mr. George Fox, of Kingsbridge, last season removed combs and bees of several colonies under these circumstances. In some of them he found a considerable quantity of honey, and in one the combs were nearly 3 feet in length and of considerable depth, several of them of this size being in juxtaposition. The bees had occupied these situations for many years. When their habitations are situated under slated roofs, and in other cold situations, I am inclined to believe that the bees usually perish in the winter, and that an early swarm repopulates the deserted combs. There was one such establishment, which, the owner of the mansion assured me, he believed to be so replenished every summer.

A gentleman in Ireland, a kind friend of mine, once asked me to remove an immense swarm of bees which had taken possession of a square open hole outside his stable wall. He had caused a front of wood to be fastened up against the open space; but as the roar of the bees was so plainly heard inside the stable, he was afraid of his horses, and wished the bees to be removed. Having properly protected myself with a bee-dress and thick gloves, I removed the board, which exposed an aperture about 1 foot square, by perhaps 9 inches in width. This was literally filled with bees. They were quickly brushed into an empty hive and tied-up, and I hoped that the queen and the entire swarm were in my possession, the owner having given them to me, if I could

carry them off. But great was my disappointment when information came from the stable, that the roar of the bees was to be heard louder than ever.

The true fact now dawned on my mind. The bees so lately secured did not constitute a swarm which had taken possession of the recess, but those clustering out from a colony which had its quarters in a narrow space between the ceiling and the floor of the loft above. The noise almost exceeded belief, and extended back for many feet, seeming to show that the combs occupied nearly all the space between the joists, running across the floor. Nothing more could then be effected, but it was agreed that on a future day, the flooring should be ripped-up and the contents appropriated. The bees confined in the hive were taken home, but, I need hardly say, perished, or deserted from the want of a queen. At that date (1852) I was not so well versed in the mode of supplying an artificial queen as at the present time.

After the foregoing operation, my host informed me he had something else to show, and we ascended to the leads of the flat roof of his house. He asked me to look down one of the chimnies, and a curious but beautiful spectacle met my view. At about 15 inches from the top of the chimney, which in that part was about 1 foot square, a swarm of bees had taken possession, building combs diagonally across the open space. The upper edges of the combs were totally unattached to any substance, so that the bees must have commenced building on the perpendicular brickwork of the chimney; yet were they most singularly regular in form. The bees were very thickly clustered level with the upper edges of the combs. The covering from rain or air was very imperfect, being a piece of slate which but partially closed the aperture, and which was put on after the bees had constructed a large quantity of combs. This stray swarm I was also asked to expel from its stronghold, and an early day was named for the purpose, but before that day arrived my kind friend died suddenly while walking over his grounds, and I never knew what was done respecting these two colonies of runaway bees.

Since writing the above the Journal has come to hand, and the letter of "A RENFREWSHIRE BEE-KEEPER" is before me. His experience in keeping bees under the circumstances, respecting which information is required by "A NORTH-STAFFORDSHIRE BEE-KEEPER," seems to have been much greater than my own, and would warrant your correspondent in adopting a trial of the plan; nevertheless, I am still inclined to believe that in a majority of cases the results will not be found altogether satisfactory. If kept in a garret at the top of a lofty house the bees suffer greatly from the wind. These rooms are also often intensely hot in summer. But the chief objection is one which is admitted by the writer of the letter before me—viz., the great improbability of saving the swarms which may issue. These almost invariably get away. It is very well to say the bees must be worked on the depriving system, but notwithstanding all the care of the owner, swarms will be thrown off occasionally from such hives. This entails no small loss, as these swarms are usually much above the average size. Where bees are kept at these elevated positions, it may be very probable that a northern aspect is best suited to them. The prevailing rough winds are south-east and north-west, often attended with driving rain. Northerly winds are seldom so boisterous (I am speaking of Devonshire now), and are drier; but the grand reason is that the bees are not so likely to be tempted out in cold windy weather with a bright sun, by which an immense mortality is caused among bees in hives facing south, or points east and west of south. That large quantities of honey are occasionally taken from runaway swarms which have established themselves in holes in walls and under roofs I have already admitted; but they form the exception, not the rule. In the great majority of instances, where I have known an assault made in these colonies, the result has been found sadly disappointing. Frequently the spoils have been calculated beforehand as likely to amount to one or more hundredweights, whereas the actual quantity obtained has been but 2 or 3 lbs., chiefly of black miserable stuff, which has been devoured by the boys and men gathered round to snatch what they could. That this does not altogether affect the question as to the housing of hives in a room must be admitted. I am glad the question has been opened. Doubtless our friend "B. & W." can afford us some of the results of his experience, which, if I mistake not, has not been small, on this matter.

It is to be hoped that your inquiring correspondent will give the plan a trial this coming season, and let the apiarian readers

of the Journal have the benefit of his experience. It is my intention to do so, if I can fit up a suitable room for the purpose, and whatever the result may be, I shall be happy to communicate it, and it will afford me very great pleasure to be compelled to modify the opinion here expressed adverse to keeping bees in dwelling-houses and analogous situations.—S. BEVAN FOX.

BEES IN CHURCHES AND OTHER BUILDINGS— THEIR DELIGHT IN RETIREMENT.

I HAVE long been convinced that bees are fond of quiet and retirement, having for some years watched their movements in secluded spots. The first colony I noticed was fixed in the end of a building at Willoughbridge Wells, near Market Drayton, Salop, the property of Mr. Meynell Ingram, of Temple Newsham, then in the occupation of his agent, the late Mr. Samuel Harding, and which building had in days of yore been occupied as a cock-pit, but was subsequently converted into more pious service and used as a chapel by Mr. Harding. I was informed the bees (which were 7 or 8 yards from the ground), had been there for years, and a more powerful colony I have seldom witnessed; but in the course of one severe winter they died, not without in the following summer another generation laying claim to and taking possession of the residence, there being no inmates to dispute their title thereto.

I was told by those who had noticed their movements, that they were several summers ere they became as formidable as the original tenants, but that they swarmed, pillaged, and destroyed as the decayed nation had done before them, and were in fact a standing menace to all the smaller bee-states for some distance round, as in the case of the bees at Hough Hall.

My attention was subsequently directed to several swarms which took up their abode in smaller buildings, but from some cause unknown they did not survive the winter, and having recollected that when a boy at the Acton Grammar School my attention had been drawn by the Rev. Mr. Wilson to some bees working over the porch (he himself being a close observer and ardent admirer of this interesting little insect), curiosity led me two years since to visit the scene of my boyish exploits, and there, to my astonishment, I found the bees in full work. Now, whether there had been any interregnum or not I was unable to learn, but the colony was of amazing strength. It is about 10 or 12 yards from the ground, the entrance being between the cracks in the stones of the church wall.

Since then I was told there was a colony of bees at Shrewbridge Hall, near this town, the residence of W. H. Hornby, Esq., the member for Blackburn, where, I believe, they had been for a dozen years; but I found some enemy had destroyed them, although Mr. Hornby's intelligent gardener seemed to think the domicile would be in the forthcoming summer tenanted again; the distance would be 8 yards from the ground.

There were several colonies in the trees of Doddington Park, the residence of H. Akroyd, Esq., which were carefully watched during the swarming season by the workmen for the swarms, but from inquiries made I was not able to discover a single colony left. They were generally fixed about 10 yards from the ground.

In Cholmondeley Park, the residence of Lord Cholmondeley; and at Combermere Abbey, the abode of the venerable hero of Bhurtpore and Salamanca, I hear of several colonies in the oak trees there, but the last summer having been so very unpropitious I was not able to follow up my inquiries.

Generally bees in this state are not to be approached with impunity, but the most extraordinary circumstance which has attracted my attention was at Sound Heath, near Nantwich. In the thick part of a walnut tree there is a strong colony of bees. This tree was originally growing at Wrenbury-cum-Frith, and was cut down last winter (and the fall of the tree would not be small), and its present owner obtained permission from the timber merchant who bought it to sever the portion of the tree which contained the bees and bring it home, a distance of three miles, when he placed it in his garden, having stopped-up all crevices.

When I visited the garden where it stands, this summer, I ascertained that the bees, which were then remarkably quiet and strong, had experienced no ill effects from the rough usage, and had every year previously sent out a swarm when the tree was growing, and it was stated to me they had had undisturbed

possession of their tenement for a dozen years at the least. Anybody acquainted with the particular odour emitted by very old families of bees could soon perceive upon approaching that it was one of considerable standing, and I came to the conclusion it was the age and toughness of the comb which had preserved the family from complete destruction, as the repercussion of the falling tree was likely to smash the contents to atoms.

Now, it strikes me that there were some of your numerous and able correspondents to take up the inquiry in the several parts in which they reside, we should soon hear of instances similar to those I have before narrated, as I read that in the year 1834 a swarm of bees housed themselves on the top of Chichester Cathedral, having taken up their quarters below the weather-cock; and I remember in the year 1850 (July), during one whole week the officers of Chester Castle were prevented from locking the gate leading to the little Roo Dee, and they were compelled to employ a whitesmith to remove the lock, when to their great astonishment they discovered a swarm of bees had taken possession of the lock, every ward of which was completely filled with honey and wax.

The height and aspect of bee-hives has for some time engaged my attention. My own are in a room well ventilated, S. by S.E., the entrances made of wood plugged in the wall 8 feet from the ground, well protected from winds, and free from noises of every description, but I am not in a situation to brag they do one bit better than those which are placed on a common bench uncared for. I, however, remember a friend who kept two colonies in his bedroom, working them through the window-frame, which did remarkably well for years, and he has been known to take a couple of eight-pound glasses from each stock, but the master and servants are now gone.

It is almost impossible to account for the singular places where bees will fix themselves. I have myself tried nearly all places, heights and aspects, but I am puzzled to find out a remedy to guard against the damp; and I am afraid our friend the "NORTH STAFFORDSHIRE BEE-KEEPER," will learn, as many have done before him, that no aspect or height will evade the penalty imposed upon us by that dread enemy, humidity.—ED. WYNDHAM JONES.

OUR LETTER BOX.

FOWL AND COW-KEEPING (E. M. D.).—You can have from our office, free by post, "The Poultry Book for the Many," if you send seven stamps with your direction. For thirteen stamps, you can similarly have "How to Farm Two Acres Profitably," which contains full directions for managing not only a cow but pigs.

SHELL-LESS EGGS (Nidus).—As the pullet has abundance of burnt shells, we think you feed her too highly, and there must be some inflammation or excessive irritation of the egg-organs. Do not give her Indian corn or animal food; but only barleymeal and boiled potatoes. It is very likely that those pullets which do not lay are over-fat.

GAME FOWL PRIZES AT KENDAL AND MANCHESTER (Fair Play).—More than one expression of reprehension of the decisions at Manchester have reached us, and we shall keep our attention fixed on certain facts. We would observe, however, that the classes at Manchester were generally more strongly represented than at Kendal; and we would further observe that no man should consent to be a Judge at a Show where a near relative is to exhibit. He may be honest, but his awards will be liable to bias, and certainly will be suspected.

PROMOTING LAYING (Susan).—Warm food is not absolutely necessary to make hens lay well, if by warm food is meant that mixed with hot water, or boiled and given before it is cool. The warmth should be the result of better and more nourishing food. Good ground oats mixed with milk, scraps of cooked meat, and an occasional handful of hempseed, are all good for the purpose. Any stimulating beyond this we hold to be hurtful.

QUANTITY OF FOOD REQUIRED BY FOWLS (A. B. M.).—Your question is difficult to answer. The quantity of food consumed will depend on the condition of the birds, and the manner in which they are fed. It is utterly impossible to say how much ninety-five head of poultry should eat. For instance, birds in low condition and coming from a bad home or run, will eat twice as much for a time as those that have been well fed, and are proportionably comfortable. We do not much approve your feeding. We would advise for Turkeys and fowls ground oats given by hand as long as they will eat them, for the Ducks and Geese whole oats. Where food is thrown down whether wanted or not, much will always be wasted; but where only a certain quantity is given just so long as they will eat with appetite, you will soon be better able to judge than we to inform you. You may vary the ground oats with some whole corn now and then.

PLEASANT HYBRIDS (Lex).—See an article in this week's paper treating of the subject.

THE SINGING-BIRD MANUAL (Bird).—It will be published this spring, and the price will be very moderate.

PARROT PICKING OUT ITS FEATHERS (Gertrude).—Put a soup-plate full of tepid water daily, where the bird can use it as a bath. If the bird does not bathe in it, pour tepid water over it through the rose of a watering-pot.

WEEKLY CALENDAR.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 45.3° and 32.5° respectively. The greatest heat, 62°, occurred on the 9th, in 1831; and the lowest cold, 4°, on the 9th, in 1847. During the period 129 days were fine, and on 123 rain fell.

SHOULD NOT THE ROYAL HORTICULTURAL SOCIETY BE MORE NATIONAL?

One of our most learned philosophers very aptly remarked, "Knowledge is power;" and yet, although the most fertile brain digs deep into the mine, analysing and scanning its contents in a way which astonishes and delights minds of a more limited compass, its length, breadth, and depth are apparently as unlimited and in-

exhaustible as ever. The progress of knowledge is undoubtedly great, and the benefits accruing therefrom no less so; but look at the thousands working all in different directions in the explo-

ration of that mine, each excellent, and excelling in the sphere to which his talents are best suited, and then form an estimate of how little really the most erudite and painstaking individual efforts can achieve.

Co-operation, however, judiciously planned and energetically proceeded with, has effected much in assisting the development of science and art. It brings together eminent men, who interchange ideas and promulgate theories which are thoroughly agitated and discussed. It brings together a host of practical men, such as agriculturists and horticulturists, who often lend force to their argument by the excellent condition of the subjects upon which their skill has been brought to bear, and all in a way contribute to the advancement of knowledge.

Horticultural societies have done their share, it may be said, to provoke emulation in the art, for they are neither few nor far between all over the country; but their influence generally is comparatively circumscribed, and the benefits resulting therefrom are purely local. In fact, judging from the complaints that emanate even from disinterested parties, the majority of the prizes are monopolised by one or two individuals, who, by dint of extra energy, and extra accommodation, and other accessories, very often eclipse their less fortunate rivals. With all this the public in general have very little to do, because it scarcely resolves itself into a national concern. Such a monopoly has a tendency to damp the ardour of those who are anxious to win the way to fame, and has a dragging tendency in the onward progress of the art; although, let it be distinctly understood that our remarks are not intended to strike at the root of any of these societies, but rather to indicate the more palpable defects, leaving amendment to time and the experience of the district managers.

Again: There are societies centred in the midst of large urban populations, which exercise a different sort of influence upon the public generally and competitors particularly, because from their resources they are enabled to offer a much more tempting field to all and sundry, whether near to or distant from the place of exhibition;

and the prizes to be gained and the honour to be won, if there be numerous entries and all above mediocrity, are prizes and honour indeed. There are Birmingham and Brighton, Manchester and Liverpool, and the great gatherings at Bishop Auckland, Edinburgh and Glasgow, Dublin and Belfast, and some others of our large and populous towns, which by their wealth and population are enabled to frame schedules of a pretty satisfactory character upon the whole, and all in their circles give a considerable impetus to the progress of gardening; but nobody who knows the real state of matters will pretend to say that the whole gardening strength of the district is represented at these exhibitions. Even go to the great metropolis, where three great rival Exhibitions exist and prosper, and where remuneration and honour are at the maximum; and whether you are surprised or not, you will find, especially among the heavier portion of the articles exhibited, that the prizes go year after year to nearly the same individuals. In fact any one, even living at a distance, who has been in the habit of taking cognisance of the names of successful competitors in the great plant-classes, could almost foretell the awards.

In a word, then, the gardening strength of the country is not represented at our great exhibitions as it might, and as it would be if we had a national Horticultural Society correlative in character and operation to either of the Royal Agricultural Societies; because few, if any, noblemen or gentlemen in the country, who keep up large establishments and disburse considerable sums towards plant-cultivation, we shall say in order to satisfy themselves and their families in the first place, will be induced, year after year, to allow their gardeners to go to either or all of the London shows, supposing the chances were ever so good. It would be quite a different affair if there were a Society of a migratory character, infusing, as it would be sure to do, a spirit of emulation in all districts, where its influence would be more immediately felt; for district would endeavour to rival district in the aggregate amount and success of the undertaking, and once such sympathy and ambition were fairly enlisted, the success of the scheme would be placed beyond dispute, and horticulture would be immensely the gainer.

There might be something said about the difficulty in organising such a scheme—in securing sufficient influence to patronise it and take it by the hand. There might be a great many things said suggestive of failure both commercially and horticulturally speaking, for there are always a few croakers ready to preach the downfall of any and every innovation, let it be ever so politic. We have only to point to the amount of opposition and hostile criticism that the organisers and promoters of these migratory Agricultural Societies had to meet with in the first instance, and to call attention now to their triumphant success, which cannot be altogether ignored as a precedent, although a little different in kind. Of course, we shall be told that no society of such pretensions could thrive out of London—that there the wealth is, and there the population—and that, in short, supposing it were set a-working under the very best auspices with the view of

promoting the science and art, it would never be self-supporting—that its patrons would never be off the road begging for its maintenance, and, consequently, death would be the end of it. Time will only solve that problem in a satisfactory manner; but if such a rural spot as Bishop Auckland, with an active managing body can get up a horticultural show, which, we believe, is now second to none in the kingdom, that will induce, as was the case last season, upwards of 20,000 people to come and see it, what will those great commercial cities which we have named not do if called upon?

Let us quote one other example of a mighty kindred gathering. When the Agricultural Society of England held its Show at Leeds little more than twelve months ago, no less than 70,000 people went through the turnstiles in one day to see that Exhibition. And may we not argue that a Horticultural Society properly organised, which should command all the influence of the horticulture-loving community of England, would achieve an amount of success proportionately great, and that such a project most emphatically warrants, nay, even demands, the earnest consideration more especially of those who have elected gardening as their profession?

There is plenty of room for the inauguration of such a Society without disturbing the harmony and efficiency of any that is already in existence, and it would go far, as has been already hinted, to draw out those who have held aloof because they have either distanced all competitors who have entered the arena with them, or else they have considered the stake at issue unworthy of their notice, and the honour to be gained only of a local, and, therefore, of a limited kind. The press by this means would be enabled to bring before the notice of their readers a much greater variety of subjects. The number of prizetakers, too, would be much more diverse, and the value and honour of the prizes much more enhanced. It would incite a community of interests unknown even in metropolitan showing, and would have a tendency to draw closer the bonds of brotherhood. I have merely initiated the idea, and hope to hear your own and your readers' views thereupon.—JAS. ANDERSON.

[Our friends well know that we have long entertained the opinion that there is open to the Royal Horticultural Society that field of usefulness hitherto unoccupied, and now pointed out by Mr. Anderson—holding an annual meeting in some country district of England, similar in character to that held yearly by the Royal Agricultural Society.

If such a meeting were held at the season of the year when the gentry of England return to the provinces, and at places so distant from London as to allow gardeners to compete who have hitherto been precluded from exhibiting in London, the Society would confer a great boon; and at the same time a stimulus would be applied to the gardening of remote districts, not only by the intercourse thus secured, but by exhibiting produce which the amateurs in those districts had scarcely deemed attainable.

We do not attempt to propose a plan by which the idea could be brought into operation; but a Committee would soon make the necessary arrangements, and local subscriptions to sustain the project, would, we think, flow in plentifully.—EDS. J. OF H.]

CROSS-BREEDING GERANIUMS.

I WROTE the answer to Mr. Darwin so hurriedly, that I made a mistake or two, which might lead readers into greater errors. Thus, "I had a commission to work over, again and again, every experiment [for changing the colour of Peas] mentioned by Gärtner and Weigmann," and the absurd assertion of "Sageret," about crossing between the Cabbage and Horseradish.

I did not try over again all the experiments they put on record; at least, not under that commission. That was as far back as 1833, 1834, and 1835, and the conclusion was, that Dr. Weigmann was not even aware that the garden Pea could not be crossed by any other Pea or plant whatever, without artificial means, and very likely there is no want of such opinions at the present day.

From thirty to forty trials in each of those years, Gärtner's assertion that he changed the colour of a Pea by pollen was proved to be wrong, and yet he very probably had a different-coloured Pea in the mother pod as he says; and if so, that was caused by a natural sport, more than one-half, if not every one, of our present race of Peas being natural sports induced by cultivation probably. But, in some cases, the change would appear to be induced by some chemical constituent of the soil in which

the plants are grown, for I know a soil which will change the bean of the Scarlet Runner to a jet black three times out of five sowings, and, no doubt, many gardeners have noticed the same effect in this and in other seedlings of their own rearing.

Again, when I said *Pelargonium* "is not a natural genus," I meant not botanically, but for the purposes of the hybridiser, in its strict meaning—that is to say, that all the species of *Pelargonium* could not cross together without destroying *Erodium*, because there is a section of *Pelargoniums* in which the species are affected in the peduncle by the pollen, exactly as the species of *Erodium*, and the species of *Erodium* are as differently affected in the peduncle from those of *Pelargonium* as the affection itself is different from the more usual course of nature. In the "usual course" impregnation would seem to be only one single process, which it certainly is not in many plants.

To explain the affection to people who know little of such subjects, let me say that a truss of such flowers is like the foot of a Game cock; the claws are the peduncles, or stalks, which support the individual flowers in a head, truss, or bunch of flowers. When the pollen affects one of such claws, that claw is, as it were, paralysed, and is drawn-in under the foot of the bird, the nail on the claw being the flower, but it is then the seed part. Now, if the effect of the pollen reached the young seed, or ovum, and put life into it, the claw would, in time, be restored very gradually from the seeming paralysis to its natural position, which position would be gained just as the seed was fit to sow, but not just quite ripe for harvest. It is a very pretty phenomenon; but being as common to gardeners as covering cold pits, few of them care aught about it.

That way of drawing-in the claws under the foot one after the other as soon as each is affected by the pollen is peculiar to about two-thirds of the species of *Pelargonium* only. The other third of the species are differently affected, and in the same way as all the *Erodiums* are. With these, the *Erodiums*, the joint of the leg above the claws, or what you might call the ankle, would seem to be out of joint, and to pull up the claws, one at a time, straight up against the leg; and by the time the seed would be ripe each claw slackens from the rigid strain, and finally turns up to take the original spread-out form as the seeds become ripe. But without the pollen, the claws or peduncles would never change out of the original and natural direction.

Now, would it not seem the oddest of the doings of Nature to undo the joint of the footstalk of a flower as the first result from the effect of the pollen, if that effect merely passed through the style to the seed in a long tube, as it is said to do? But when you have five hundred wild species, and a multitude of seedling flowers, which go directly to prove the footstalk out of joint, or affected by pollen, although the seeds of none of that vast number of plants had been touched, or affected at all, the mind of man could hardly conceive a greater error in natural history than the way they say the pollen reaches the seed; and yet nine-tenths, if not all, the learned professors of botany of this generation believe that way firmly.

Lastly, when I said I obtained a real cross from "Scarlet Defiance, which is over fifteen years old; but I may be mistaken," I ought to have said that I believed Defiance was fifteen years old, though I might be mistaken about its age, not mistaken as to the cross, as the sentence might be taken to imply.

I would ask, in return, Has any gardener obtained a real cross from this Defiance during the last fifteen years, and if so, what is the name of the seedling, and who let it out? It may be of some use to cross-breeders to know the reason why I ask this.

It took me eight years to obtain that cross, and yet they say I ought to know all about such ways. Some years I touched over a hundred of its flowers without a fertile result, and yet I was quite sure the pollen took a certain degree of effect; for the footstalk of a great number of the flowers touched relapsed to the perpendicular downward position, but some did not, because the pollen I made use of was foreign to the kind.

If a plant is absolutely barren the footstalk cannot be thus affected; and when we say a plant is barren because we cannot force a seedling from it, we may be saying what is not the fact. Of one thing, I think, we may be sure in a seedling of *Geraniaceae*, if the peduncle yields to the effect of pollen—namely, that that seedling is not naturally barren, though we may fail to force it to seed. And that is what I wish that cross-breeders should bear in mind, and therefore endeavour by a change of treatment—such as a warmer or a colder climate, a different

soil, and a differently aged plant, with different degrees of health and strength in the plants—to obtain the desired cross.

Even should all attempts fail us, we may rest assured the cross is obtainable in some other locality or country differing from our own.

Then, if that be true of Geraniaceae, and I can see no cause to doubt it, there can hardly be a question about its not being an isolated fact in one order of plants only; although we cannot discern it in those orders where the process of fecundation is positive, or effected at one stage of the process.

I said, long since, that the surest way to effect a difficult cross in Geraniaceae was to subject the mother, previous to attempting impregnation, to a sudden check, and that was how I overcame the inertness of Scarlet Defiance, although I failed for seven years even by that move; but another move seems to have been equally necessary. The plant, for the eighteen months preceding the period of that seeding, was kept at, or as near, the starvation-point as could be without killing it; the poorest sandy soil, and the smallest pot to cramp the roots in, with no more water than to lift the leaves after they all flagged, was the treatment repeated through two summers.

The fact is, that plant was a giant sport, and it was necessary to reduce the giant to the level of its ordinary kindred before it could seed by the pollen of any one of them; and I have found it necessary to reduce it considerably in strength before I could seed it by its own pollen, which makes me anxious to learn if it has been found more easy to effect by any one else whose soil and treatment might be very different from mine.

I am supposed, by many, to know more about crossing than many others, which obliges me to be so much the more particular about everything I have to say on the subject. But every one of our readers who has a turn for crossing knows just as much about it as I do, for I know nothing of it which is not down in these volumes, and some may know much more of it; for all the cross-breeders over the country have, each one, their own peculiar breeds to work on, and, of course, every one knows something, practically, which no one else can know so well for the want of practice in that particular breed. One thing, however, we all know, and that is, how very little the best of us really does know about it. Depend upon it, there are scores who have never crossed twenty kinds of plants in all their practice, who can tell you twice as much about it as the most practical of us who have been at it all our gardening lifetime. They can do every conceivable turn in it without going out of doors; we, very little indeed, even if we devote our whole time to it. But the greatest difference between them and us is, that they can account for every effect produced, which enables them to foretell events in crossing; while we cannot reach farther than our experience places before our eyes. D. BEATON.

FLOWERS OF THE PAST SEASON.

PANSIES.

MANY are the conjectures and terribly magnified pictures which are presented to us from time to time, of the condition in which this "tight little island" would be if the Gulf Stream through any disturbing cause, were to be diverted from our shores. And, by-the-by, may we not say, in passing, that this is one of those things so little dreamt of by many, for which we ought to take shame to ourselves that we are not sufficiently thankful for those daily and unnoticed mercies which a gracious Father is ever bestowing? We have been enjoying a winter mild beyond description—we, perhaps, think too mild. We see our Roses pushing, buds of our Currants and Gooseberries swelling; and, as is our wont, we shake our heads, and only "wish we had a little sharp frost to keep things back," little considering what a boon this has been to those poor distressed souls in Lancashire, or to the large mass of still more destitute creatures who, in our great metropolis, are exposed to a depth of misery that Lancashire knows nothing of.

Well, the Gulf Stream has not deserted us, and we are, I hope, thankful. But what has that to do with Pansies? Nothing, except in the way of "a circumbendibus." That stream has deserted us in the south, and we are fain to look northwards now for the cultivation of this pretty spring flower; nor do I think that the position in which it is placed, or the manner in which it is disparaged, is either at all fair, or at all likely to advance its cultivation.

I am quite as sanguine as to the future of the Fancy Pansy

as any one can be. I believe that Mr. Dean, of Bradford, is likely to do wonders with it; but I do not therefore see any reason why the old love should be cast away. Then the Royal Horticultural Society has thrown its weight into the adverse scale by offering lower prizes for florists' Pansies than for Fancy ones—prizes, indeed, so small in amount, as, I fear, not to make it worth the while of any grower to send them. The whole meaning of this is, that a few persons have taken it into their wise heads that there is too great a sameness in Pansies; and that by the way of obtaining variety it is best to squelch them altogether. It is a somewhat novel doctrine; but perhaps people are becoming so very wise now-a-days that they must be drawn out of the old trammels. I grant that there is a great deal of sameness, but so there is in every florists' flower. Look at a collection of Tulips worth hundreds of pounds, or at one of Fuchsias or Pelargoniums: it is surely just the same thing there. The person who grows them can see variety. He will pay his money for new flowers which he believes in some one or more points to be better than others which he has, and his opinion is scarcely worth more than that of a mere outsider. Imagine the horror with which Sir Octavius Oldboy would regard you if, after taking you through a room rich with the plunder of Egyptian tombs, you were to say, "Dear me, Sir Octavius! these are all very much alike!" And do you not think, if you were merely a looker-on and knew nothing of the real merit of these images of "Pasht" and other Egyptian dealers, it would be rather more modest to hold your tongue? "Alike, sir! As much alike as you are like a monkey! Look here. Do you see this one is of bronze and that of earthenware? Look at the size of this compared with that; mark the peculiar expression in these eyes; and I can only tell you, sir, that if you have any that you think like these, I can very soon show you that there are differences which you cannot appreciate." "Well done," says your companion, "I think you caught it there;" and probably the result is, you have learned a lesson that may be of benefit to you through life. When any one, then, runs down a box of flowers because of their sameness, let him only have the owner standing by, and probably he will learn a lesson that may in the same way teach him to be a little more modest for the future. And, then, do the decisions of Judges falsify this notion? There were, for instance, four or five first-class certificates given to seedling Pinks this year. I think they deserved it; but I will undertake to place these in a box of twenty-four, and that not one of those who are not growers of Pinks shall be able to see the difference between them and other varieties in the same stand, while a practised eye will at once pick them out. So long, then, as amateurs are satisfied that the new varieties of any florists' flowers are of sufficient merit to warrant their purchasing them, and so long as constituted courts of appeal, comprising the most competent persons to decide on such questions, continue to give prizes and certificates to such new flowers, so long do I consider it to be simply an absurdity for complaints to be made of their sameness.

I have thus attempted to vindicate the Pansy from this charge, or at least to put it on the same ground as other florists' flowers, and indeed we might say greenhouse and stove plants as well—for where they are grown in collections the same charge may also apply, as, for instance, Ferns. Take any one division of these you like, and then see the minute points from which growers will determine that a difference exists, and the distinctions of the florist will not seem to be a bit more minute.

One must now say a word on the present position of the flower. Its admirers, are, I fear, becoming fewer than ever, the difficulty of keeping them through the summer having deterred florists from growing them. The last two summers have, however been favourable, and may, perhaps encourage others to try them again. Be that as it may, it is to Scotland we now look for new varieties—a fact most certainly more complimentary to the perseverance of the Scottish growers than to the propitiousness of their climate; for one almost wonders how they can not only withstand but overcome the terrible foes of cold, wet, and wind that they have to contend against. To one of the several firms who are in the habit of raising and letting-out new Pansies I am indebted for the opportunity of seeing a few of the novelties of last year—I mean Messrs. Downie, Laird, and Laing, of Edinburgh, and Stanstead Park Nursery, Forest Hill; and the following are the notes that I have been enabled to make. I see that they are again advertising a batch of new ones, amongst which a self named Masterpiece seems to be pre-

eminently distinguished. They have besides Ajax, Alexander Tait, Baroness, Leonard, Miss Hay Newton, Mrs. Wyllie, Thomas Martin, William Austin, and Carlos.

Albee Downie.—Light, creamy white ground, the belting rich dark purple; blotch dense and clear; shape beautifully round.

Charles Watson.—A very fine dark bronzy purple self, the petals very smooth and the shape good. This flower was awarded a certificate by the Scottish Pansy Society in 1861—a good proof of its value, as the Society is very chary of its certificates.

Elgaro.—Yellow ground, belting a bright bronzy purple. Distinct in its appearance.

Miss Berry.—Deep golden yellow, belted with bright bronzy purple; blotch very distinct and clear.

Miss Williamson.—Pure white ground, belted with deep purple; blotch dense and clear. A very nice flower.

Rev. Thomas Downie.—Deep golden yellow ground, deep bronze purple belting. An excellent show flower.

Telegram.—Yellow ground, deep purple belting. A large-sized flower of good properties.

Vesta.—White ground, belt moderately broad; colour rich purple; blotch and eye dense and good.

Wallace.—Deep yellow ground, very rich in colour, belted with broad deep purple. Of excellent quality.

William Merricks.—A very handsome flower. Ground colour pure golden yellow, belt rich purplish-crimson; blotch very dense.

These seemed to me the most striking of the flowers I had an opportunity of seeing; and I think any one may fairly add them to their collection with a good expectation of being pleased with them.—D., Deal.

CALANTHE VESTITA CULTURE.

THE principal object cultivators have in view in growing plants is the production of flowers, always, of course, excepting such plants as are cultivated on account of their beautiful foliage. Now if any one were to tell a lover of flowers how to grow them so as to double or quadruple the number of flowers any given plant could be made to produce, such information, no doubt, would be gladly and thankfully received. I think I am in a position to give such useful information to the growers of at least one species of plant—the above-named lovely Orchid, *Calanthe vestita*.

I had occasion lately to visit my young friend Mr. Abel North, gardener to T. Shorrocks, Esq., the Lodge, Ashton Mersey, near Manchester, and whilst there I, of course, had a look at his Orchid-house. Though an old grower of Orchids myself, and having visited at least nine-tenths of the collections of these plants in Great Britain, I cannot but confess that I never saw such a display of flowers on this *Calanthe* as I saw there. He had 12 pots, and each pot had on an average twelve spikes of blooms, most of them 3 feet long; I counted the flowers on one selected at random, and it had thirty-five flowers on it. So eager were the pseudo-bulbs to bloom, that many of them had two and some three spikes each, some even flowering from the side and top of the bulb.

They were growing in eight-inch pots of the ordinary shape. There were from six to eight bulbs in each pot. I inquired the means he used to obtain such successful results; and Mr. North, being no niggard, answered my queries very fully.

His pots during March, cutting-off all the roots, and uses the following compost:—One-third caky cowdung, two-thirds turfy loam and leaf mould, adding a moderate quantity of river sand, passing the whole compost through a coarse riddle; he then drains the pots effectually, and places a layer of what remains in the middle over the drainage.

In potting, the largest bulbs are chosen, and put in the pots at equal distances from each other. The smaller bulbs are put into large pots, and grown on till they attain the required size. No flowers are allowed on them till they are fully grown. But little water is given at first; but as roots and leaves are pushed forth more water is applied, and a liberal allowance of that element is given till the plants are in bloom, then the quantity is gradually reduced, and the plants allowed to go to rest for three months or thereabouts.

By following this method any one may be equally successful in blooming this winter, or, at least, late-autumnal-flowering

Orchid. Florists who grow flowers for sale would find it worth their while to cultivate this free-flowering Orchid for the purpose of making bouquets of its long-lasting flowers. It does not require a very high temperature, nor any very nice attention. Any ordinary stove would suit it well.

Like all other terrestrial Orchids it requires a period of rest, a period of growth, and a time to bloom. When at rest keep it rather cool—say from 55° to 60°—and just dry, but not parched so as to shrivel the bulbs.

I noted also in bloom a fine specimen of a good variety of *Dendrobium nobile* 3 feet high and as much through; also *Cypripedium insigne*, a remarkably handsome plant with ten flowers all expanded at once; *Oclogyne cristata*, with many spikes of beautiful pure white flowers; *Bletia Tankervilleæ*, *syn. grandiflora*, very strong, with fifteen spikes; and lastly, the old, yet handsome, *Zygopetalum Mackayi*, well bloomed.

The East Indian Orchids, I observed, were healthy, most of them showing several spikes of bloom, particularly *Ærides*, *Saccolabium*, and *Vanda*.

The collection is not large, but very select, and in most luxuriant health—a fact very creditable to the manager, especially when it is remembered that he has only had the charge of them for little more than two years, and never had the care of Orchids before. Let this example be an encouragement to all good, zealous, plant-loving gardeners never to fear undertaking the management of Orchids, if, like Mr. North, they are determined to spare neither time, labour, nor patience in the cultivation of this most interesting and singularly beautiful tribe of plants.

In the stove I observed many fine specimens of the better kinds of Ferns, which at this time of the year are more remarkable for their beauty than in summer, when there is more floral display.

The greenhouse contained some handsome specimens of New Holland plants—such as *Boronias*, *Pimeleas*, *Aphelexis*, *Epacris*, &c.

The whole place is neatly kept, showing industry and that test of good gardening—attention to minutiae.—T. APPELBY.

AN AMATEUR'S NOTES ON M. DU BREUIL'S SCIENCE OF TRAINING FRUIT TREES.

ON looking over, the other day, some Numbers of last year's *JOURNAL OF HORTICULTURE*, an inquiry for a book on the pruning of fruit trees caught my eye, and the answer it met with, to the effect that there was no special work to be had on the subject.

This vacancy in horticultural literature has been supplied from a foreign source. Our neighbours across the water, with the logical severity that characterises them, take a pleasure in reducing everything to rule—from the framing of a political system, it appears, to the formation of a Plum tree. No Englishman has the least wish to see our old Constitution, irregular as its growth has been, submitted now to the pruning-shears and cut to the approved continental fashion, whatever finish it may be promised in the process. But there are many who will welcome a logical treatise on gardening.

M. Du Breuil's book by some persons may be thought dry. It contains no rambling gossip, no friendly jokes, no superfluous illustration; but it has the merit of always keeping to the point, and the rare charm of lucidity. How is it that an amateur finds it so difficult to master the various minute directions with which treatises on gardening abound—a difficulty so great as to deter many of us from all further researches into the matter? I believe it will be found mainly owing to the want of this same logical precision in the writers. Even Mr. Rivers—whose genial temper, evident freedom from professional jealousy, and liberality in unlocking to us amateurs some of the arcana of his art, attach to him every one interested in gardening—does not, it must be confessed, write plainly. How many times had we to refer to his book to ascertain the number of inches to be pinched off this branch, or off that—in this month or that—on this kind of tree or that—whether it were two, three, or four, we never could remember until we had learnt elsewhere *why* they were pinched at all. How much more intelligible the teaching which first gives the principles and axioms of the science, the habits of the tree, and the laws that govern them, and then on this basis rears the superstructure of practical directions. There was a well-known tutor in a certain university, who used to say that he could never remember anything unless he had a peg to

hang it on. In gardening we have hitherto been allowed no pegs to carry our memoranda, which, in consequence, are found sadly mixed together in the pocket when needed for use.

M. Du Breuil's treatise, therefore, appears to me to deserve a hearty welcome, if only as a step in the right direction. Whether his easy dictum will stand the test of experience remains to be proved; but the calm and dignified composure of his tone, his simplicity and brevity, seem to elevate horticulture into the rank of the exact sciences.

An instance of this lucidity is his practice of invariably distinguishing the pruning necessary for the formation of the tree from the pruning which is intended to insure the annual crop of fruit. In most treatises we find one set of directions for pruning the Apple, and another for the Plum; but no division of this kind, although the two kinds of pruning mentioned above are most distinct in their aim and object.

M. Du Breuil's favourite trees seem to be the Pear and the Peach. For the Pear he describes at length six modes of training. "The pyramid," which by the way, is twice the height and size of the tree with which Mr. Rivers has made us familiar; "the goblet," fitted for windy gardens; "the cone," or cypress-shaped tree, which seems to be a pyramid with less strongly-developed branches; "the Verrier palmette," which may be described as a horizontal espalier with the termination of the branches carried up from a horizontal to a perpendicular position, each lower branch being outside, and in its angle embracing the branch above it—the shape one sometimes sees in the arms of a candelabrum. This is intended for the wall, and takes fourteen years to complete.

Then comes "the cordon oblique," which has been already described in Mr. Bréchant's interesting *brochure*, in which the trees run up the wall at an angle of 45°, presenting in their closely-spurred and rounded form some distant resemblance to a cable. Lastly, we have the "double contra espalier in vertical cordon," which, if its name does not frighten them, will, we think, win the favour of many a cottage gardener.

Imagine a double row of Pear trees, each a slender stem of 9 feet high, the rows close together, 6 inches only between them, while the trees are planted zigzag, that one row may not shade the other. Twelve inches separate tree from tree in the row. Thus each tree has a radius of 6 inches for the utmost limit of its branches; a leafy cable 9 feet in length, thick set with spurs and fruit-buds. The trees are secured from wind by strong posts sunk into the ground at every 20 feet, and connected together by fencing-wire. This wire steadies a nine-foot lath to which each tree is fastened. Copper wire, it strikes us, would be lighter than a lath, and shade less. What a picture in autumn this lofty, leafy wall studded with yellow fruit! How safe from wind! how easily protected in spring! It is twice as fruitful as "the pyramid," the author assures us, comes into bearing in half the time, and attains its perfect form in six years.

But this wall of foliage will not be complete without the low edging which M. Du Breuil wishes to see accompany it on either side. About 1 yard from its foot he carries a dwarf hedge of Apple, formed by a single rod running horizontally 18 inches from the ground, and pruned as a cordon. The trees that nourish this rod are planted 5 feet apart, and bent horizontally, till the stem of one overtakes and touches its neighbour, into whose stock its extremity is then inarched. In this way, when the line is complete, the sap flows continuously through the whole, and the closely-united brotherhood become an exact emblem of the strong ministering to the necessities of the weak. These are also held in their place by low posts and fencing-wire.

The directions for Peach-tree training are quite as minute. He equally admits only two methods for this tree, "the cordon oblique," and the fan-shape reduced to the exactitude of a mathematical system. The illustrations here, and, indeed, throughout the book, are profuse, evidently copied from living specimens, and in every way admissible; they add greatly to the value of the work.

Standard Peaches in orchard-houses he does not contemplate. But much of great service to the orchard-house cultivator may be learnt. It is not uncommon, for instance, to find the laterals on a too-luxuriant Peach producing 3 inches of bare stem without a bud either upon it or at the base. For this evil, which will throw next year's wood too far "from home," M. Du Breuil has a remedy. By suppressing all flower-buds at the winter pruning, and half-severing the lateral at its base, he compels it to emit wood-buds there.

Here is another wrinkle. It is known that a fruit-bud may be

grafted in August on the Pear, and bear fruit the following year. M. Du Breuil tells us that this graft has the extraordinary effect of making all the fruit on the branch above it larger than they would otherwise be. He compares it to the effect produced on fruit by an annular ring taken off the bark—a method applied, I believe, by English gardeners to branches of the Vine.

At page 156 is a statement which will cause, some surprise. "It may be thought that the blossoms upon these small branches unaccompanied by a wood-bud, must prove sterile, and ought to be cut off at pruning, as though of no value. Quite the contrary, however. Experience proves that these blossoms produce the finest fruit." And he straightway recommends the shoot to be cut above a fruit-bud, although there are no wood-buds upon it anywhere except at the base.

Those who send fruit to exhibitions will be glad to learn that it is possible to administer a tonic to the objects of their anxiety, and that they are very much the better for a solution of sulphate of iron.

The several plans for equalising the growth of the tree, reducing the gross, and invigorating the feeble branches, will be found interesting. Trees are capricious, and will have their *enfants gâtés*, favourite gluttons, and rude robber-shoots; but none are allowed to remain in the well-disciplined *gymnase* of M. Du Breuil. "*Suaviter in modo, fortiter in re*," is his motto. Without the least harshness, but by the never-failing, almost imperceptible pressure of a dominant will, the plethoric rebel is brought into order, and made to abate his pride. His head is bent on one side out of the way of the stimulating sap, or the foliage which matures it for his uses is half clipped from him, or his spirit is tamed by pinching, or his heart broken by being made to carry all the fruit, or he is hampered by imprisonment and close nailing, while his poor brother wantons in the wind; or if the worst comes to the worst, a dark hole formed by an overhanging shutter brings him to his senses, and all the while his sickly brother is made much of, petted with a tonic, encouraged by the best places, and allowed to run riot as he pleases; till he is strong enough to match his rival, and win his fair share of the maternal juices.

The translation is tolerably executed; but in another edition, which will certainly soon be called for, it will be well to avoid such gallicisms, as "extension," used throughout the book for last year's growth, and "anticipative" bud (page 69), which seems to mean wood-bud. Some obscurity is caused by the use of the word "branch," which in common English is used to denote a shoot of some size, but here is applied to small shoots, spurs, and even embryo fruit-buds.

How are we to understand the following (page 175)?—"When the shoots of the successive branch extensions have attained a length of about 3 inches, suppress only the buds behind; then the double or treble buds;" which after some study we take to mean, "when the shoots from last year's wood have attained the length of 3 inches, suppress the shoots behind the branch, and also the double or treble shoots."

At pages 72, 138, 160, 178, and 180, other errors have caught our eye. Are we to suppose, too, that the cost of copper wire is so great in France, as to make a wire trellis amount to 5s. per square yard, which is half as much again as the cost of the wall in an English stone country?

We are left in the dark as to what are Mr. Wardle's contributions to the present edition. His remarks are sometimes imbedded in the text, and sometimes are found in footnotes. It would have been better if they had been confined to the notes altogether. We should then have had M. Du Breuil's directions fitted for a southern climate, and the necessary qualifications and adaptations to our own in notes. As it is, we do not know at times whether we are listening to the opinions of M. Du Breuil, or those of his translator; and, on the other hand, some statements that need explanation in England, as, for example, that Apple trees suffer from heat, are left as they are.

But these are minor blemishes easily removed, and all who love the fruit garden are indebted to the writers who have brought to their notice this well-considered and scientific treatise.—WYESSIDE.

BEURRE SUPERFIN PEAR.—This Pear has kept with me wonderfully well this season. I have still (Jan. 23rd), five fruit left. I am not sure I had any ripe in September, but I had it through October, November, December, and a few in the present month. Can this be said of any other good Pear? Those that

have kept till the present month have been small and medium-sized. Some of the fruit have been much richer in flavour than others, and most delicious, and when at its best I believe this fine Pear to be beaten by none, and equalled by very few.—E. B.

PLACES OF PUBLIC RESORT.

SUNDERLAND PARK AND WATERWORKS.

The great facilities now offered for travelling by the many lines of railway by which the country is intersected, and the opportunities thus afforded being in so many cases taken advantage of, the necessary interchanges of ideas, customs, or habits in the communications of one class with another, are tending fast to remove local peculiarities; and the customs of remote districts are certainly becoming modified through the instrumentality of the young people, and probably through some of the older ones too, who have travelled for information. True it is, nevertheless, that local circumstances must ever maintain a difference. Cornwall and Cumberland, though both hilly, differ widely in their vegetation, climate, and other features; Norfolk and Derbyshire cannot be compared together. There is, however, one thing in which all seem to agree, and that is improvement. Some of the customs of bygone days may still be held up as golden rules, but there are great numbers of them open to improvement; and one of the best tokens that all the advances in the various departments of industry have not been made under the grovelling spirit of tending to individual gratification, is that the public at large have been thought of; for in most of our large towns public libraries and reading-rooms have been thrown open to all classes, while museums and other sources of intellectual cultivation have been enriched by many and often well-directed endowments.

Other and by no means the least useful of all the places of public resort are parks or pleasure grounds of easy access to all. Doubtless the immense advantage of the London parks to the densely populated districts by which they are surrounded led, in the first instance, other large towns to attempt something of the same kind; but some of the first steps that way were certainly much in advance of the times—such, for instance, as the Arboretum at Derby, which, however worthy, as it doubtless is, and ever will be, of the munificence of the donor, is nevertheless bordering on a higher standard of arboriculture than the million are yet prepared for. Something equally pleasing to look at and easier to comprehend is what is wanted by the generality of our park-strolling company. But the gratification of the latter is by no means so easily accomplished as it was twenty years ago. So many gardens of the very highest class and best keeping having been thrown open to public inspection during that time, the public taste has risen to a degree bordering on fastidiousness; and Criticism so rife on public gardens, parks, cemeteries, and such like places, that unless a considerable amount of taste and skill be exercised in the formation of anything fresh, woe be to the unfortunate individual on whom the public displeasure will fall. Nevertheless, with all the vaunted knowledge which is to be attained by existing examples, now and then serious blunders are made.

The Great Exhibition of 1851, which had no precedent to guide its managers, was nevertheless an acknowledged success in every respect, while there are certainly some very grave errors in the present one of 1862. The building and its fittings cost very little short of three times what the Crystal Palace did, yet everybody admires the cheap one, and condemns the dear one as supremely ugly. The builder doubtless expected his large domes to attract attention; but John Bull does not care for glass domes—their inutility is transparent. In truth, it is the fact of being able to see completely through them from the outside that offends the eye and diminishes their size; and yet from the cost of the building it is only fair to suppose that these two huge glass domes, about which the public do not seem to care a pin, cost as much as the whole building of 1851.

There are many opinions, too, on the Kensington Horticultural Garden; but censure here has certainly in many cases been unjust, for in so small a place, and surrounded as it is by myriads of chimneys, it would have been utterly impossible to have given it the sylvan scenery some writers pant after. Architectural, sculptural, and other artificial ornaments were almost all that could be adopted: therefore I can find but little fault with it except in name. It is certainly a misnomer to call it a horticultural garden at all, when perhaps not more than fifty or say a hundred species and varieties of plants are cultivated in

it. Plenty of cottage gardens belonging to humble labourers could furnish a more respectable array of names. Failures, however, are as useful monitors as successes, and tend by comparison to enhance the value placed on the award of public approbation.

The course of public opinion on matters of interest in which it is concerned is, nevertheless, sometimes carried on to a mischievous length, and factious opinions instead of conscientious ones are often enough put forth; even great societies are sometimes the means of deceiving the public. Fortunately the freedom of opinion is accorded to all, and this in some measure secures us against great mistakes. And, as the will of the mighty public is more potent than that of most mighty men, most of our public undertakings are the subject of more care and anxiety on the part of those who execute them than private undertakings are. Great taste is often shown in buildings and other works that are far from costly, and some public parks or gardens will vie with those of any nobleman or even Royalty itself. Where is more variety collected into a moderate space than is shown at Birkenhead? Other places are rising into fame, while some, which from their natural disadvantages can never be expected to occupy a prominent place in cultural matters, are, nevertheless, equally important for other reasons which render them at all times pleasing and agreeable, if not also instructive objects of interest. Such a place is Sunderland Park, of which the following short description may, perhaps, suffice, since the general bearings of such places have been more extensively treated of.

SUNDERLAND PARK, generally so called, occupies an elevated position immediately adjoining the southern edge of the town. Originally it was a quarry, and it was on the waste stone and rubbish that the formation of it had to be carried out. The southern side of the plot showed the face of the rock where the workings had been left off, and this, being some 40 or 50 feet high, forms an excellent feature in it. The high and bleak situation of the whole, and its being only about half a mile from the seashore, precluded all chance of cultivating many of the shrubs and plants often found in more genial situations; but the formation of the ground, the excellent walks, and the annuæ, creepers, and such shrubs and trees as will withstand the chilly blasts of the German Ocean, gave to the whole an air of neatness I was hardly prepared to find in such a place. The ground that had been excavated and been left in irregular heaps, had been in some degree altered, not by levelling but by increasing the size of these mounds and in all cases rounding their tops. Curved walks of a beautifully grey-coloured stone-shatter, hard, firm and smooth, wound along the valleys in various directions; and what appeared well worth copying in other public gardens was, that in most if not in all cases the walk was in so deep a cutting that the sloping turf edges could not be walked on, while at the same time they were so nicely adjusted to the walk as to leave the latter of a regular and uniform width and a faultless outline. All who have had public walks to deal with, well know the anxiety of so many to walk on the turf and its consequent wearing away, but here I did not see a single gap or blank—in fact, the steep character of the edgings made it difficult to set foot on them.

Some of the mounds were capped with clumps of shrubs, but the ungenial climate was fatal to most of these. In the more sheltered recesses they were a shade better, and some at the base of the rock promised to grow up; but it was evident only a few of our general garden favourites were able to endure the keen sea air. Of the most healthy were *Cotoneaster microphylla*, some Ivy, Poplar, Vine, and other things, but I do not remember seeing the Tamarisk, which certainly ought to do in such a place. But the great beauty in summer lies in the annuæ, of which there was an excellent assortment and all in a thriving condition; while in winter the beautiful dryness of the walks, the rock with its perennials and creepers, and the excellent turf by which the whole of the space not occupied by walks or beds is covered, will give it always a cheering aspect. Amongst the annuæ occupying the very highest part of the ground, were excellent French and African Marigolds, Stocks, Delphiniums, Dianthus, Calliopis, and other popular annuæ; and hanging from the rock were Sedums, Saxifrages, Wall-flowers, Ivy, Nasturtiums (which by-the-by I also saw in another place not more than a stone's throw from the ocean), Vines, and, what I believe would do very well, *Cineraria maritima*. In the bottom and in a more sheltered position were some beds of Scarlet and other Geraniums, Verbenas, Calceolarias and other

bedding plants in tolerable order; but annuals were the most gay at the beginning of October. It ought also to be mentioned, that a bronze statue, said to be of great merit, of General Havelock, whom Sunderland claimed as a townsman, occupies the highest part of the ground; near this is also one of those trophies so often met with in towns of less note—viz., a Russian gun. The Havelock monument is, however, well placed, and is said to be a good likeness of the hero, and the view from its base is very fine. A forest of masts is seen over the tops of the houses in the foreground—further off the glittering ocean, dotted here and there with specks of human handicraft slowly making their way to their destined port; and the town itself, though less ornamented with church-spires and monuments than some of more ancient date, is seen to possess few of the dirty narrow lanes and slums which disgrace so many cities of more renown.

A peep at another public work will show that mere utility need not necessarily banish the beautiful, for in this both are combined.

SUNDERLAND WATERWORKS.—It is not usual that this class of undertakings is in any way connected with gardening matters, but the managers in this case have given their works such an ornamental character in the gardening way as to entitle them to notice—in fact, the floral beauties and good-keeping of the place make it a fashionable resort for those who do not object to a walk of a mile and a half from the town, and that mostly up-hill, for the waterworks are on very elevated ground, commanding the highest buildings in it. The salubrity of the air is great as well as the excellence of the water, to obtain which a steam-engine is at work lifting one hundred gallons each stroke, and that twelve times a minute, and yet the noise is little, and of dirt there seems none. Very large basins of the crystal fluid, in which very small objects may be seen 12 feet deep, are surrounded with terraced walks, and these are bordered with turf-edging kept scrupulously neat, while the vacant ground is carved up into slopes, flower-beds, and borders, with groups of trees near the entrance.

Near one of the boundary-walls, which was covered with Roses and some Ivy, were groups of the most fashionable bedding plants of the day. Petunias seemed to do better than near London; *Lobelia speciosa* was flowering very well; while *Geraniums*, *Verbenas*, *Ageratums*, and *Calceolarias* were pretty good; and *Gazanias* remarkably so. Amongst annuals were *Saponaria*, *Asters*, *Stocks*, *Phlox Drummondii*, *Mignonette*, and French and African *Marigolds*, with some few patches of *Gladiolus*, all in good keeping; and in an out-of-the-way corner I noticed some common *Primroses* bedded-in under trees, doubtless to be brought forth for winter decoration. Amongst shrubs were some rather promising *Yews* and *Ilexes*, and the excellent keeping of the whole reflected great credit on all concerned. To my mind the raising of 1200 gallons of the purest water per minute from the bowels of the earth was not the least imposing feature, and the machinery seemed neither bulky nor noisy. The Directors in making their grounds so ornamental deserve the thanks of all, and it is to be hoped they will derive other and more substantial advantages as well. J. ROBSON.

VINDICATION OF GÄRTNER—EFFECT OF CROSSING PEAS.

In my last communication I said that Gärtner had proved that the colour of the Pea in one variety of the garden Pea may be changed by the direct action of the pollen of another differently-coloured variety. Mr. Beaton authoritatively remarks on this: "Gärtner never found that—he only asserted it; and when he was pushed to the proof he lowered his sails, made a second edition of his great work, and confessed many of his errors." He adds, "No cross-breeder of any practice in England at the present day would like to have his name associated with that of Gärtner for or against any exploit in crossing."

I should have taken no notice of this, although I should be sorry to lie under the imputation of having made an entirely incorrect statement, and although it is not pleasant to be flatly contradicted; but I wish much to be allowed to endeavour to vindicate the memory of one of the most laborious lovers of truth who ever lived. It is painful to see a long life of honest labour repaid by contumely from a fellow-experimentalist, who, I suppose—anyhow I hope—never read one page of the great original work—namely, the "*Bastarderzeugung*," published in 1849, a mine of wealth to all who will explore it.

Gärtner, when young, and at the very commencement of this long work, committed a very foolish action; he crossed a

number of plants belonging to distinct genera without having taken due precaution to exclude insects, and when he found their capsules full of seed, he thought that he had succeeded in crossing them. With the enthusiasm of a beginner he most unwisely published the result, and to this first paper Dr. Herbert has alluded with proper blame. When Gärtner found his seedlings came up pure, he, like an honest and excellent man (as all who knew anything of his life will admit that he was), publicly confessed his error.

Gärtner's great and last work, entitled "*Versuche über die Bastarderzeugung*," contains in 790 closely-printed pages the detailed results of nine thousand distinct experiments in crossing, together with admirable observations on the whole subject of hybridisation. This is a greater number of experiments than, as I believe, have ever been published by any other man, even by Kölreuter, and a far greater number than those published by Dr. Herbert. One great superiority in Gärtner's work over those of Kölreuter, Herbert, and others consists in his having actually taken the trouble to count the seeds in the capsules of every cross and hybrid which he made. He kept an exact record at the time of making each experiment; and this I have reason to believe was not done by Herbert, and certainly has been very far from the case with other English experimentalists.

I cannot resist here mentioning—as some who honour, as I do, the memory of Dr. Herbert, might like to hear the fact—that I have reason to believe that the last words ever uttered by Herbert were on his favourite subject of crossing. I called on him in London, and saw that he was very feeble. I wished to leave him, but he stopped me, and talked with much interest on this subject. An hour or two afterwards, as far as I could judge by the published account, he was found dead in the chair in which I left him.

But to return to the Pea-question. An account of the various crosses made by Gärtner (he selected the most constant varieties) between differently coloured Peas, with the results given in detail, will be found at page 81 to 85 in his "*Bastarderzeugung*." Gärtner was led to try these experiments from doubting the accuracy of Wiegmann's statements, and he found many of them incorrect; but he was compelled to believe in the Pea case; not that Peas can be crossed with Vetches, to which other statement of Wiegmann Mr. Beaton alludes. I may add that Gärtner knew of the account, published in vol. v., pages 234, 237 of the "*Transactions of the Horticultural Society of London*," on the influence of pollen on Peas. In an old volume of the "*Philosophical Transactions*," vol. xliii., page 525, there is a full account, with every appearance of truth, of Peas in adjoining rows affecting each other. The Rev. M. J. Berkeley has, as I have been informed, subsequently to the publication of Gärtner's book, tried again the Pea-experiment with the same result. —CHARLES DARWIN, *Down, Bromley, Kent*.

GOOD-GRACIOUS PANSY.

WE observed in your issue of 20th inst., a letter of protest against the name given to the Double Pansy now offered for sale by us, and we shall feel greatly obliged if you will insert the following in reply.

The plant was submitted to the notice of Mr. Beaton, and spoken of by him in No. 66 of your Journal, page 248, under the name of "Good-Gracious" as follows:—

"The 'Good-Gracious' Double Bedding Pansy was sent in the name of Messrs. Carter & Co., and had a first-class certificate from a flying quorum of the Floral Committee, for they all seemed on the wing; but besides the Sub-Committee, who were appointed to do the honours of the Summer Shows, there were the Chairman, J. J. Blandy, Esq., and the Rev. J. Dix, who take the Chair in turns; the Secretary, Mr. Moore, and a lot of us; and we were unanimous in the award. Many ladies also seconded our resolve; and you may expect it next spring as cheap as it is good. But I have not yet had its genealogy, further than that it is a Devonian.—D. BEATON."

When we gave the plant the name of "Princess Alexandra," we had forgotten that Mr. Beaton had already introduced it to the notice of the public in the pages of your Journal under the name "Good-Gracious;" and not wishing to confuse the public by offering the same plant under different names, we of course reverted to its originally-published cognomen. We do not, however, wish it to be inferred from the foregoing observations that we agree with your correspondent's opinion, and desire to

throw the presumed blame upon Mr. Beaton: far from it. The name may be inelegant, and that is the only objection to it. To say that "Good Gracious" is a profane expression is simply absurd; and who that was not morbidly sensitive would ever dream of attributing blasphemy to it? We entertain the highest veneration for sacred subjects, and for their professed exponents, and we must say that in our humble opinion both have been, to say the least, unnecessarily brought forward in this matter by your correspondent.—JAMES CARTER & Co., 237, 238, *High Holborn, London.*

[Having now published the objection that some of our readers take to the name of "Good-Gracious" applied to a flower, and having also published what Mr. Beaton and Messrs. Carter have to say in its defence, we will close the controversy, so far as our columns are concerned by observing, that though we do not consider the name profane, yet it approaches too near to the vulgar to be a desirable name for a flower. There is but a shade of superiority in "Good Gracious" over "Oh, my eye!" which would not sound pleasantly though applied to a very wondrous Rose.—EDS. J. or H.]

ROYAL HORTICULTURAL SOCIETY.

HIS Royal Highness the Prince of Wales, feeling "that he is contributing towards carrying out the wishes of a beloved parent, that the memorial of the Great Exhibition of 1851 should be inaugurated with every circumstance of honour," has consented to inaugurate the memorial on the 5th of June next, being the anniversary of the opening of the Royal Horticultural Society's Gardens in which it stands.

At the anniversary Meeting on February 10th we understand that Sir Daniel Cooper, Bart., the Rev. Joshua Dix, and J. Kelk, Esq., will be proposed as new members of the Council; William Wilson Saunders, Esq., as Secretary in the place of Dr. Lindley, resigned, and who, we believe, will be proposed as a Vice-President in place of the Bishop of Winchester, who retires; and John Clutton, Esq., as Treasurer.

ABUNDANCE FROM A SMALL SPACE— BROCCOLI CULTURE.

It is a very popular notion, that one requires a considerable degree of insight into the mysteries of the art of cookery to be able to boil a Potato well, and yet no vegetable is more generally and extensively cooked than the Potato. It is profitable as a crop, easy to cultivate, and generally liked, so that almost everybody makes use of it. Thousands cook and eat it, and yet it is only a good cook who can boil a Potato well.

Again: Who being in possession of a plot of ground does not try to cultivate one or more of the numerous tribe of Cabbage-works? Yet for all that, it requires a very skilful cultivator to grow any of the Cabbage tribe well under the numerous difficulties which many gardeners find in the way. I do not mean to imply those who have space, for then the principal difficulty is removed. Provided there is sufficient labour and space, the difficulty of keeping up a supply of vegetables is not great; the ground can lie fallow for a short time, provided one crop is off before it is time to put another in, and all may go on comfortably. This is not the case with regard to small plots which are sometimes devoted to kitchen crops, and which are often made to produce as much as gardens of much larger dimensions.

I do not intend to speak in any way disparagingly of those who cultivate vegetables on four or five acres of ground, that being the size of the kitchen garden; but I do mean to assert, that more credit is due to him who manages to supply a family with vegetables all the year round from a quarter of an acre of ground. In fact, I have known this done when the same extent of ground has been thickly planted with fruit trees and bushes. How it is done it would be difficult to describe; but it can only be by careful watching and untiring industry, managing so that one crop shall be half grown before another is done with; that what is lost during the growth of one crop shall be replaced; and that the ground shall be kept exceedingly rich and fertile while its resources are severely drawn upon: and, perhaps, here is the main secret, for it is a fact that the handling of stimulants is a very delicate matter.

When soil becomes thoroughly exhausted it appears to become filled with minute organic forms, which seem injurious to the growth of garden crops. The endeavour to enrich it often

increases the evil and sours it instead. Many swarms of grubs may be traced to the manure applied, and plants may be easily destroyed by manure given in a liquid state; and it requires some considerable practice to be able to know to a nicety just what plants require, and to give no more.

It is in consequence of this knowledge that many gardeners, who are otherwise unknown, are able to achieve much with very limited means—a talent for making the most of everything so that there is no waste.

It may appear like stretching the matter to say, that two or three dishes of vegetables and salads every day in the year—all kinds of fruits, as Apples, Pears, Plums, &c.—all kinds of wall fruits, bush fruits, and Strawberries—can be supplied from a kitchen garden of little more than a quarter of an acre. It is nevertheless a fact, and probably the details would be worth knowing if they could be made intelligible. It is not, however, my intention now to enter into details even if I could, but to make a few remarks on the culture of Broccoli—one of the most useful classes of vegetables that can be grown, especially for winter and early spring use. Yet Broccoli is a most exhausting crop, and does more towards impoverishing the ground than any other, and where it is continually grown requires some management to make it sufficiently productive. The question is, therefore, not so much how to grow it, as how to grow it profitably on the same spot year after year, and at the same time to obtain other crops from the same ground every year also.

If ground is to produce so much more than the average it will be necessary to make good the loss sustained; for this is not usually done in the ordinary method of wheeling manure on to the ground and trenching it in as the crop comes off.

Everybody who writes about kitchen-gardening makes it a point to urge trenching as a matter of the greatest necessity. The fact is, I think, this is too often overdone. It is not always good for plants to root deeply into the soil. If a tree forms a tap root and goes deep into the soil, it is generally an unfruitful one; and if a Cabbage or Broccoli roots deeply, it runs to leaf and stalk, but makes a very poor head.

What is wanted in a plant or a tree is a mass of close fibres near the surface, and it is then sure to be productive. I have trenched the ground preparatory to planting Broccoli on many occasions, sometimes deeply—as much as 4 feet—at other times not more than a foot, adding plenty of manure at the same time, but never did I find any satisfactory results proceed from it. A friend of mine, an ingenious and industrious gardener, once told me that he used to trench the ground deeply for Broccoli, but never found it do well. At last he left off trenching and it answered better. He even planted it in hard ground where he had to use a crowbar to make the holes, and then it grew much better than when planted on trenched ground. "I will never," said he, "plant Broccoli again on newly-trenched ground." Of course, some allowance must be made for the quality and texture of the ground. I very much doubt if light ground is ever improved by trenching.

However, to return to causes. The principal one is in making good the loss of matter drawn from the ground by the previous crop, and in supplying the succeeding one with a proper quantity of suitable food. This, of course, is given in the form of manure. The usual method is to have a load or two of rich-looking, highly-coloured stuff drawn in at the moment it is required. I doubt if half the good is ever done in this way that is supposed. There are colour and sometimes smell, but are these the necessary qualities required by plants? I venture to say not. On the other hand I think a plant looks for something rather different as its natural food, and takes manure only when it is in such a condition that its constituents are ready to decompose or part asunder without being under the influence of putrescent fermentation, and that is when it is neither disagreeable to the sense of smell, sight, or feeling—not that plants are supposed to be possessed of these senses, for it is not known that they are; but then they do absorb nutritive matter, and it must be in a condition that is not unpalatable to them.

From this I deduce that manure ought to be perfectly rotten, and, to make it still more sweet and natural, it should be mixed with a like quantity of soil (good turfy loam I prefer); that two years is a very good time for it to lie together, after being well mixed, before applying it to the ground; and that every year when a part of the heap is used a like quantity ought to be added to lie together the same length of time.

Here is presented the chief difficulty. Very few people care to devote a portion of their ground to a store of manure, and still

fewer to keeping it so long. The most important part of the business is considered the most objectionable; but it must be surmounted, or the plan I would recommend of growing good crops on a limited space cannot be accomplished. However rich and fertile the ground may naturally be, such crops as Broccoli soon alter the texture of it; and I, for one, put more faith in good sound manure and fresh soil than in phosphates and other salts, given, as they are and should be, in homœopathic doses. But where there is a will there is a way; and the means of concealing a heap of manure, or of turning it to account while it is undergoing decomposition, will present themselves readily enough if desired.

Of the three most important points to be attended to in the cultivation of Broccoli in small gardens, keeping the ground firm is the first—that is, as far as my own experience goes; for, having had chiefly to deal with light ground, I can affirm that I never knew Broccoli do well in it if planted soon after it had been trenched, although the experience of others may give a contrary result. Next comes manure, which has already been spoken of; and thirdly, the distance of planting them from each other. We are sometimes told to clear Broccoli of dead leaves as the winter approaches. Now why should this be necessary? If a plant receives plenty of room at planting it makes a short thick stem, and spreads out its broad vigorous leaves covering a yard or 4 feet, or even more, no dead leaves being visible, and if you happen to lift up the leaves in damp weather you will see the surface of the ground so covered and shaded completely matted with small active fibres. Now spread 3 inches of loam and dung over those fibres, and the plant will continue to grow, and no leaves will die; for, from its receiving a continued supply of proper food, it does not require the constituents of old leaves to build-up fresh, and then when frost comes the plant receives no injury, for the leaves droop and cover the stem—a provision of Nature which ought to be noted and allowed for.

So, then, in planting the Broccoli, first choose strong healthy plants that have been pricked-out from the seed-bed. Plant them, if in rows, not less than 4 feet apart and not less than 3 feet apart in the row, and do not plant till the soil has been run together by the rains of the last three months or so, at least if the ground is light; but remember, no manure need be dug into the ground. When the plants have grown considerably lay about 3 inches of it on the surface, without digging it in, and there need be no fear that the plants will not find it, for

what the fibres do not reach up to the rains will wash down to them. All this may be done between other crops, such as early Peas, Beans, &c.

It is one of the most common mistakes to suppose that the closer plants are packed together the more is obtained from the ground. It may be so with regard to individual crops, but as respects a succession it is a great fallacy. In sowing Onions, Parsnips, Carrots, and such dwarf crops, sow two rows about a foot apart, and then go about 4 or 5 feet and sow two more. Let the intermediate space remain till the time for planting winter crops of Cabbageworts, and plant one row of these through the centre of this bare five-foot space. They will cover the ground after being treated with manure as described, not dug in, but laid on the ground between and about the stems, covering the roots, and preventing evaporation. There will then be no necessity for clearing away dead leaves, or laying down to protect from frost—a plan which I have often adopted to my cost, for the mice attacking them have eaten out the hearts, and spoiled the crop.

With respect to sorts, no better authority can be given than late Numbers of THE JOURNAL OF HORTICULTURE. I have usually grown the Walcheren, because it yields for a length of time. I grow Early Cape on account of its not coming in all at once; Snow's Winter as a winter crop; Purple Sprouting as a profitable crop; and Miller's Dwarf, from its hardiness and lateness, yielding heads almost till autumn-sown Walcheren comes in again. I have occasionally grown other sorts, but find their particular points of excellence are of more consequence to the large than the small grower: therefore it is unnecessary for me to enumerate them. The same may be said of the time of sowing, for able pens have already done much on this point. I consider March the best time for sowing early sorts, and April for late ones.

But there is one practice I would recommend—that is, never to plant the first and strongest plants from the seed-bed. I once had a fine crop of Purple Sprouting Broccoli. I chose the very best plants I could find, and let them run to seed; there were no other plants of Broccoli or any other Cabbagewort seeding within a long distance of them that I knew of, and yet when I sowed the seed and planted-out the strongest plants they all came green and ready; but the second planting was perfection. Since then I usually throw away the leading plants from a seed-bed.—F. CHERRY.

THE HORSE CHESTNUT.

IN the reign of George III., there happened to be at the same time two members of the House of Commons, one of whom was Montague Matthews, and the other Matthew Montague. They similarly differed in politics, for one voted for the king's interests in preference to those of the people, whilst the other always voted the other way. On one occasion the Royalist's opinions were attributed to the democrat, which started the latter from his seat to assure the House that though they bore the same names, yet they as much differed as did a chestnut horse from a Horse Chestnut.

Quite as mistaken was our contemporary, "Notes and Queries," when it gravely informed one of its inquirers that the Horse Chestnut is so called because the fruit is given to horses! Its name so implies; but if horses could speak, they would assure our contemporary they never eat anything with a flavour so disgusting. Gerard may have been right, who wrote about the period when it was first introduced here, when he said it is called "Horse-Chesnut, for that the people of the East countries do with the fruit thereof cure their horses of the cough, shortness of breath and such-like diseases;" but we rather think that the prefix "horse," was merely employed to denote harshness and powerful flavour, as in the case of Horse-radish.

Its native dwelling place is among the mountains of Thibet, but it came to England direct

from the Levant, though a few years before, as Parkinson observes, "our Christian world first had the knowledge of it from Constantino-ple."

Here, we have at present, only to "make a note of it," as an ornamental tree. Gilpin thought it too heavy and too roundheaded, and when planted alone it is not libelled by that description; but we have seen it very effective when grouped with conical-formed trees, which broke the monotony of the outline formed by the Horse Chestnuts.

The double-blossomed variety has the additional merit of continuing longer in bloom than the single-blossomed.

"*ÆSCULUS HIPPOCASTANUM*, var. *FLORE-PLENO*. (Double-flowered Horse Chestnut.) — *Nat. ord.*, Sapindaceæ. *Linn.*, Heptandria Monogynia. It is a rather uncommon, and a very ornamental tree, equalling in vigour the common sort, from which it differs only in its double flowers. These are very showy, having a strong resemblance to those of a good double Hyacinth; they are pale blush, with deeper red at the base of the petals. Our figure was made from a specimen communicated by Mr. Rivers, of Sawbridgeworth, who informs us that he received it from the Continent about eighteen years since. The spike of flowers we have represented was not so long as is usual, owing to the tip having been killed by frost in May. The trees flower when quite young." — (*Gardeners' Magazine of Botany*.)

Æsculus hippocastanum flore pleno.

A FEW DAYS IN IRELAND.

WOODSTOCK.

(Continued from page 75.)

On the north side of this wall are the usual sheds for gardening purposes, flanked with beds of flowers, and backed with rich masses of Rhododendrons. Well back, so as to have plenty of light, are three or four ranges of houses and pits, with broad walks between them. A walk at the west end and a bank of Rhododendrons separate these from the conservatory, which stands at the north end of the first raised terrace. These houses were well supplied with plants for growing and forcing in winter—as Cinerarias, Primulas, Oranges, Justicias, Ruellias, Poinsettias, Euphorbia jacquiniæflora, bulbs &c. Other houses were filled with Fuchsias in bloom, Oranges, Camellias, &c., and all in good condition. We noticed a number of fine healthy plants of *Cantua dependens*, which is managed successfully, if we recollect aright, by resting the plants in summer and growing them in January. Most are more or less span-roofed houses; and a fine one, devoted to Pine-culture, is covered with Hartley's best rough plate-glass. The Pines, planted out and in pots,

with and without hot-water pipes beneath them, were in the finest health, stems thick, leaves short and stubby. In this and another house Vines in pots are forced early with great success, the pots being placed beside and over an open gutter through which a hot-water pipe passes. To enumerate all the outs and ins of these houses would require an article. Mr. McDonald traced something of the fine condition of the Pines to the rough glass, which he considered allowed more of the beneficial rays of light to pass through than even the clear plate. He had evidently studied deeply the subject of light in reference to glass houses, and we should be glad to have a detail of the conclusions at which he may have arrived, as in general we are rather in a maze on this important subject. These houses—those in the walled-in gardens and the conservatory—are heated by one of Weeks' tubular boilers, and a tunnel takes away the smoke, the most of which, however, is consumed.

From these houses we mount a granite stair and stand in front of the circular conservatory with domed roof, the roof being coloured delicately blue, and the bottom glass a light grey, thus requiring no shading and giving rise again to questions of suitable colours in glass. In order not to confuse our readers, however, it will be better to step through the walled garden and come out at the gate of blue and gold at H, where the three flights of steps stand facing us, and such a combination of bright colours presents itself to the right and the left, and on three different levels as can rarely be witnessed. We first find ourselves in the middle of a parterre next the wall, formed of T-beds. We rise six steps and we are on terrace H, 36 feet wide, formed of circles in chain pattern, extending to the right to the conservatory, a distance of we should say more than

170 feet, and to the left even considerably further, and terminated by a fine iron circular garden seat, of a bright blue and yellow colour, which is backed by a group of evergreen Oaks. Each circle in these chains is 12 feet across. We mount to the next terrace, which is of the same width and length, and which is formed with a chain of diamonds, with blunted triangles in the openings. These diamonds are 18 feet across.

The T-beds next the wall would have looked very well anywhere else except in the vicinity of the larger and more dazzling masses on these two upper terraces. We made a number of memoranda but from a drenching rain they became much obliterated. We must, therefore, confine ourselves less to particular than to general features. First, We were glad to find the beds well raised in the centre, the circles not only being circular in

their circumference, but circular across, forming more than the half of a globe. This is different from the practice of some people, who must have their circles a dead level. Mr. McDonald stated, with great truth, that "the elevating of the beds added a third to their surface, and different colours were shown-off with much better effect." Second, The beds on each side of these flights of steps were planted to match, as uniformity in such cases is always pleasing. The second and third beds, &c., generally follow suit. Each bed is intended to be a picture in itself; whilst, at the same time, it either contrasts with, harmonises with, or shades into, its next neighbour. In some beds the colours are contrasted, in others they are shaded; many Scarlet Geraniums are shaded-down, whilst the variegated sorts are shaded-up. A splendid shaded diamond bed consisted of Mrs. Maylor, Trentham Rose, and Princess Royal. Spitfire Geranium set-off to great advantage the immense trusses of Glendinning's Scarlet Seeding; and again, Spitfire formed a fine ground for what Mr. McDonald styled the "dazzling Stella of Beaton." Hardly any Verbenas are used in these terraces, except such a bright sort as Lord Raglan for lighting-up Lady Plymouth Geranium. No Calceolarias is so much esteemed as amplexicaulis; and even after the torrents of rain, its bright lemon colour and its large loose trusses or panicles were very charming. Variegated Geraniums are often mixed, not formally but in little groups, so as to present a broken surface. We have forgotten to state that the amplexicaulis Calceolaria is planted in peat and sand, which seems to answer well in the moist climate of Ireland. The best-coloured leaves we have seen out of doors of Farfugium grande were on this terrace. Third, There was every evidence that not only great thought had been exercised in the planting of the beds, but that they had received unintermitting attention ever since in regulating, thinning, and nipping, so that a shoot or flower should not be out of place. The beds, therefore, though full were not crammed, but the plants had room to grow; and such edging plants as Golden Chain were close to without touching each other. A high finish is given to the whole by the beds being covered neatly with moss, which was as green as if grown in a shady wood. We have tried moss several times; but in hot weather we could not keep it green, even if the birds would have let it alone. In a few hours they would scatter it over gravel or lawn. These beds at Woodstock would seem to say that the feathered tribe had not learned to scratch and tear there.

Now for an opinion, for we will not venture to criticise. This terrace of circles is the most telling and massive affair of the kind we have ever seen; thanks, not only to the planting of the beds, but to the treasures of our lofty friend Mount Alto. The pearly white spar that surrounds the beds, and the bright red gravel that forms the walks next the glass, render the whole a picture of great beauty. If anything seemed to be wanting, it would be a few elevated plants to break the uniform level of that mass of diversified beauty; but even on that we should be afraid to venture. In the upper terrace of diamonds, the beds are quite as beautiful and as well managed every way as the terrace of circles, and yet it seemed to us much less satisfactory. This was solely owing to the whole of the triangles on each side being filled with white spar. We do not object to the colour, but to the baldness and low level of the colour, though variety even here would not be unpleasing. Coloured gravels have a good effect round regular clumps, or even in dividing figures in a group; but we have never been satisfied with them when they formed the only garnishing of clumps themselves, when these were connected with other beds planted with flowers of tolerable height. Such composition-groups interfere with unity, even as respects level and outline. The raising of certain beds, or of particular plants in these beds, above the general level, has a very different effect from a whole series of beds having patches of colour sunk so much below the general level. To maintain this unity, even as respects the level outline of the picture, the white of these triangles ought to be as clearly seen from a distance as the flowers in the diamonds, which could only be done by either elevating the white gravel or sinking the plants, so that the masses of flowers should not be on a much higher level than the gravel, which, of course, would spoil the beauty of the picture. Convinced of the refined taste of the proprietors and their manager, it is not without diffidence we express the above opinion; but, considering the almost overpowering somewhat-level splendour of the circle terrace, we would be inclined, for variety, to plant these triangles, and to have the central plants as high as, or, rather, considerably higher

than the central plants in the diamonds. The fine gravels may then be used between and for walks as now. Without such planting, we think more unity would be secured by removing the inner lines of the triangles, filling the whole of the space with one kind of gravel, and having the walk of another colour. There can be no better opportunity for ventilating a subject which is daily absorbing increased attention. Our simple idea is, that a regular clump in a parterre should be filled with plants; or, if mere colouring material is used, there should be unity as respects level.

We now pass on to the circular conservatory that stands at the end of the terrace of circles. The outline of this elegant house, built by Mr. Turner, of Dublin, is, therefore, peculiarly appropriate. Elegance and lightness are its marked features; the lofty dome has given the key-note to the inside arrangement, the plants being grouped in blunt rounded pyramidal form. In the centre was a fine plant of a dwarf variety of the Date Palm, supported with Musas, Hedychium Gardnerianum and coronarium, the latter adding its sweet white flowers to the attractions of its fine foliage. Then there were fine plants of Begonia fuchsoides, with huge clusters of depending blooms, fronted with fine-foliaged plants of Begonias and other genera, and relieved by noble plants of feathered Cockscombs, gold and crimson, and huge masses of Vallota purpurea, many counting fourteen large flower-stems in a pot. From the roof were suspended baskets of creepers and climbers, allowed to hang over the baskets, and also mount on wires. Instead of the common round pot, ovals and other shapes were used; but even these did not seem artistic enough for such a scene. A gentle shower can be sent over these plants from the roof when desirable; and we may mention here that the hose and the pipe can be freely used in watering elsewhere, which is a great advantage. From the conservatory, over the flower-beds, over the Oaks that back the fine garden seat, a fine outline is obtained of the mountains of Carrigurn. Some lovers of uniformity might wish that another conservatory occupied the site of the elegant garden seat.

From the steps at L, the sloping lawn on the left side of the Irish Yew-walk, from L to M, though open in places, is massed with shrubs, which conceal all view of a roseroy and bulb garden beyond; these gardens being again blocked-out from each other by masses of Rhododendrons, &c. On the right side of that Yew-walk, and reaching to the boundary farther back than the line of the conservatory, the sloping lawn is open, and on it are clustered the finest specimens, with one exception, of the Pine tribe at Woodstock.

The walk is terminated by a seat at M, and in the background is a fine plant of the Cedar of Goa, with a diameter of head of 50 feet, and the trunk near the base $2\frac{1}{2}$ feet in diameter. On the lawn such kinds as Pinus insignis were as green as if there had been no severe frost in England in 1860 and 1861. Among Araucarias and Deodars was a fine plant of the latter 30 feet in height, which had become diseased when young, and had fresh strength given to it by being grafted on the Larch. The following were fine plants from 30 to 40 feet in height:—Pinus excelsa, Ayacahuite, ponderosa, pinaster, Hartwegi, &c., with recurring branches, and apulensis, with fine graceful foliage; Abies cephalonica, Douglasii, morinda, &c.; Picea pinsapo, Webbiana, &c.; with smaller plants of nobilis, Wellingtonias, and other choice kinds; also fine, thick, upright specimens of Cryptomeria japonica, and one of the finest specimens we ever saw without protection of the Cunninghamia sinensis, from 30 to 40 feet in height. From the end of the walk at M fine peeps are obtained, between these specimens, of the terrace gardens and the ribbon-borders through the gates in the walled garden. At this point we should think the height would be fully 150 feet above the level of the bowling-green.

Turning now to the left side of the walk we soon enter into a roseroy, the beds being oval in form, surrounded with arches for climbers, and a straight walk so arched leading to it and from it from east to west. In an open space of lawn near it stands the exception above alluded to, the unequalled specimen of Araucaria imbricata, above 40 feet in height, and the bole 21 inches in diameter near the base. The great beauty consists not so much in the size of the plant as in the density and luxuriance of the main branches, and the drooping character of the branchlets—a beauty of which even a photograph gives little idea unless looked at through a proper glass. Proceeding north-westward we come to a beautiful summer-house close to the boundary, from which fine views are obtained of Brandon Hill, side views of Saddle Mountain, with cottages on the cul-

tivated land, and fine spiral trees in the foreground. Returning eastward by a fine curved walk, backed with masses of Rhododendrons and specimen Cypresses, &c., along the sides, leaving a Boxed bulb garden and a splendid fountain on our left, we again cross the lawn and come near the steps at D and E to obtain a good view of the Araucaria-avenue.

This avenue is at present 600 yards in length and 50 feet in width from tree to tree, the trees standing 30 feet apart from each other in the row. One charm of this avenue is the sloping rising ground on which it is placed—somewhat similar to what we have shown in the pleasure ground. A second charm is its being backed on each side with masses of flat-headed and spiral trees; a third consists in the present termination being somewhat closed by a John-O'-Gaunt arch, formed by a fine old Scotch Fir on each side; and a fourth charm will be found in the mode of planting for securing health and a natural appearance to the trees. Note here that most if not all of those plants had previously been planted in different places at Woodstock; but they had fallen into a very unhealthy state, the hard foliage being crusted with green slime through deep planting and stagnant moisture. To remedy this, a deep track, more than 5 feet deep, down to the rock or slaty bed, was cut 40 feet behind and parallel to each row of Araucarias. On the site for each tree two or three loads of rough stones were placed chiefly below the original level, and then on that a mound formed of twelve loads of good mixed earth. Meanwhile the whole plant of every specimen was carefully scrubbed with soap water and small brushes, and well syringed with clean water, and in many cases the roots were also washed, and the whole were planted in December because there was most time then. So well was that planting done, that plants some 6 feet in height without stake or tie never swerved from the perpendicular, and were fast becoming as distinguished for green luxuriance, as they were previously marked by a sickly hue.

The surface of the avenue was a little rough when we saw it, but a fine, wide, hard promenade of grass has been made along the centre, higher than the ground at the sides. The bottom was formed of schist and granite gravel, the finest at the surface, mixed with peat and well pounded till solid; on this a thin turf was laid, fine soil scattered over it, then sown with Hard Rescue Grass seed, and thoroughly rolled so that a horse may gallop over it almost without leaving marks of hoofs. We can believe the latter fact thoroughly, as the finest grass walk we ever saw, was one that had been allowed to form itself naturally over a disused well-drained gravel path.

Standing at the end next the mansion the Scotch Firs make such a nice termination that we are perfectly satisfied; but when we reach where these Firs stand, a hankering desire comes over us that the avenue should be continued a considerable distance farther on to the boundary of the deer park, so that the eye would rest on the sky outline and the fine masses of timber beyond on Mount Alto. We see no objection to this, except exposing the substantial wall of the deer park, but that could be concealed either by a covering of Ireland's evergreen creeper or a bank of turf. We can well imagine that this matter of fences is one of great importance; as, though there are some thirty-five acres of dressed ground, and a range of ornamental grounds averaging one mile in every direction from the mansion, and these are all substantially fenced, you never by any chance see a boundary until you come right up to it.

Turning eastward and southward from the top of this avenue, we traverse a fine open glade formed of dense masses of Oaks and Pines, with newer things at the sides, and through the wood that leads to the glen, passing in our way huge masses of the Flowering Fern, *Osmunda regalis*, until we reach the Swiss cottage—a private picnic rendezvous for the proprietors and their friends. Of the antique furniture, table service, library, &c., it is not our province to speak. The position is beautifully picturesque and romantic, close to a precipice overhanging a dashing waterfall. Before reaching the glen fine views are obtained of the distant Carlow mountains, and southward, near New Ross, of the meeting of the Nore and the Barrow—

"which long Sundered do at last accord
To join in one, ere to the sea they come;
So flowing all from one—all one at last become."

The glen is a lovely place, especially on a fine summer's day. There is now the sweet murmur and the rattling din of the streamlet as it emerges from a quiet pool or battles with a huge boulder rock, or rushes down a precipitous incline or fall. There are the narrow paths, with nothing artificial about them except

a few flints and stones in the softest places, winding round along the almost precipitous at times and at others more shelving banks; whilst these banks themselves are clothed with luxuriant timber, and all suitable openings planted with Deodars, Araucarias, and others of our best Conifers. In addition to the other undergrowths, we ever and anon meet with the New Zealand Flax in flower, great masses of different kinds of Ferns—as *Aspidiums*, *Aspleniums*, *Athyriums*, *Blechnum boreale*, and *Ceterach* in great abundance; *Lastreas*; *Hymenophyllums* in large patches; *Woodsias* rather scant; *Polypodium vulgare* in great beds, and lesser patches of *bifurcatum*, *cambricum*, *dryopteris*; plants of *Trichomanes*, and plenty of *Scelopendrium*s in different varieties; and here again huge plants of *Osmunda regalis* 10 feet in height and 30 feet in circumference of head.

We must confess, however, that grand as was the picture, we were not in the best mood for particularising its distinctive features; for, feeling some twinges of rheums the previous night, when the thunder rolled and the rains poured, as they can do in Ireland, we would have fled to the nearest shelter but for something like a feeling of shame and cowardice; for there walked Mr. McDonald as unconcerned as if clothed with ducks' wings, and there stood the ladies, who honoured us with their company, admiring some romantic view, or stooping to gather some extra beautiful Fern-frond, or so wrapt in the admiration of the beautiful that they

"skelpit on through dub and mire,
Despising wind, and rain, and fire"—

not even holding their bonnets, and leaving ribbons and crinolines to look after themselves. Surely, surely the worthy old sage who once gave us the advice as the essence of wisdom, "Never walk with a lady on a rainy day if you can help it," could never have had the opportunity of observing with what a calm philosophy our sisters could look upon such an occurrence in Ireland.

We were, therefore, glad to reach the Red House, situated close to the river, with fine views upwards and downwards, and about a mile distant from the mansion. With the exception of the terraces, &c., near the mansion, which can only be seen by application, the whole of the rest of this beautiful demesne is open for the enjoyment of visitors. The Red House is, as it were, set apart for their comfort; and the chief employment of the people who lived in it seemed to be to minister to their happiness. A large upper room is set apart for picnics, banqueting, fiddling, and dancing. A nice drive of nearly two miles takes us to the village of Innistioge, by the side of the river. After the glen this is somewhat tame, though furnishing fine peeps of the mansion and grounds, and Mount Alto in the background, until, passing the line of the mansion, we come to the precipitous bank, which we have already mentioned. As we come to a cottage on the side of the river, a waterfall tumbles down from the opposite bank, only a little less lofty than that on the side on which we stand. The whole road to Innistioge from this spot is charming—the luxuriance of the trees; the wreaths and long ropes of Ivy, Clematis, and Woodbine; the masses of creepers and Ferns—and the introduction of such thorough mountaineers as Conifers, Deodars, and Araucarias would, as they grow, add still more grandeur and grotesqueness to the scene.

Noticing the gates at Innistioge, a fact came out incidentally well worth chronicling. These gates are locked at a certain time in the evening, but are opened for egress on request. A party had kept merry at the Red House until the short hours of the morning, and on arriving at the gate, though belonging to what are termed the upper classes too—the lower classes would not have done it—because the people in bed could not hear them quick enough for their fancy, they burst open the gates and took them from their hinges. Many, indignant, counselled inquiry and exposure; but Col. Tighe simply wished the gates to be put right, and no notice to be taken; no doubt concluding that the reflections of the wrongdoers must, to a certain degree, be a punishment.

Through the kindness of the estimable proprietors, we had a drive over the Fern-wreathed bridge of Innistioge along the rising ground on the opposite side of the river, and through the cultivated land between it and the hills; went through the buildings of a nice compact farm homestead; partook of whiskey and biscuits in the parlour of the nice substantial house, that had handsome plants in the windows and a flower garden in front; and noticed that the cottages in our route, built and building, that came in so nicely in the views from Woodstock,

were built with a greater regard to comfort than any mere picturesque effect. From that elevation the whole of Woodstock, the mansion, terraces, blue-domed conservatory, glades, masses, and the splendid backgrounds of Mount Alto, come in as a charming picture.

Farming is also carried on with great spirit under the supervision of Mr. King. We had only the opportunity of admiring the neatness of the homestead; the cleanness of all carts, ploughs, and utensils; the fine appearance of cows and horses; and the extra luxuriance of a large field of Mangolds and Carrots—the Mangolds being in rows about 33 inches apart, and the Carrots in rows between the Mangolds. These Mangolds Mr. King often keeps good till the following autumn.

And now we must say adieu to charming Woodstock. Much of its beauty must be seen to be appreciated, much we have left untold, much, no doubt, we have forgotten; but we shall not easily forget the brotherly communicativeness of Mr. McDonald, the kind attention of his fellow servants, and though last, not least, the courtesy and generous hospitality of the proprietors, which we valued all the more because, looking on them as a proof—additional, no doubt, to others of a more tangible character—that they fully appreciated the services of their talented superintendent.

R. FISH.

GRAPE-JUDGING.

I MAKE no doubt the readers of your valuable Journal will think enough has already been said respecting the question of Grape-judging at our future exhibitions. I am not about to criticise the views of previous correspondents on the subject, neither do I support them; but must at once admit that I have not yet seen the subject brought forward in a direct way, supporting what, in my humble opinion, is the most important feature in Grape-judging and Grape-growing—viz., the colour.

We shall, no doubt, soon be made aware of the alterations to be effected in this all-important question; but for my part I cannot perceive any reasonable grounds for any alteration whatever. Many will ask, Why should Grapes not be tasted as well as other dessert fruit? The question appears feasible enough, but in my experience I have always found the best coloured Grapes to be of the best flavour—far before those of more inferior colour; and so long has it been customary to judge Grapes by their colour, &c., that I think it will be long ere exhibitors will reconcile themselves to the system of having their Grapes tasted.

We are all aware that by far the greatest number of exhibitors bring their Grapes deficient in colour. This, I think, is owing to the idea that when a Grape commences its colouring it requires no farther care; and not only does a Grape look well when thoroughly coloured, but I think we cannot call it brought to perfection unless it is so.—HARRY.

RAISING BEGONIA-LEAF AND OTHER CUTTINGS ON HOT-WATER PIPES.

LATE last autumn I had some of the choicest kinds of Begonias sent to me. Not having at the time a place I could allot to them with a little bottom heat, I was rather at a loss what to do with them.

Just at the time I was about to start my winter crop of Cucumbers, and being desirous to raise some plants from these fine leaves, I took some old half-inch slates and placed pieces on the hot-water pipes in the Cucumber-house. I filled some 60-size pots half full of potsherds, filling up the remainder with leaf mould, a little fibry loam, and about half an inch of silver sand on the top.

I cut the leaves into wedge-shaped pieces, about an inch in length, and inserted them in the sand as thickly as I could, and then placed the pots on the slate, where they obtained a steady bottom heat. Some might think it was rather dry, and so it would have been had I not sprinkled the slate over with water two or three times daily. The cuttings wanted little or no watering, the moisture of the house being ample.

In a very short time each piece of leaf had produced a young plant. As they had done so well I put in some more store cuttings—such as of the Croton, Cissus discolor, Vincas, Clerodendrons, Hibiscus, and many others, besides a lot of Lycopodiums, &c., which struck in a comparatively short time.

I potted them off when struck into 60-sized pots, and placed

them again on the slates, where they soon made a rapid move, and so did all the other plants above mentioned.

I soon found they wanted a shift, when I gave them a 48-pot, and placed them again on the slates, where they grow very luxuriantly and soon made large plants. I then removed them to a rather cooler house, where they stood until Christmas. Then some of them were placed in a silver vase and stood upon the dining-table, and I think nothing at this season of the year could look superior than a healthy, compact, and well-grown Lycopodium.

Well, the time came for Chrysanthemums. As soon as the shoots were 2 inches long I had them put in. I had twenty-five sorts and I filled twenty-five pots, as above stated about Begonias—sticking the cuttings in as thickly as I could, and placing them in the same house; and in about fourteen days the pots were full of roots. I potted them off, and placed them in another house with a rather lower temperature. I then put in a batch of Verbenas, variegated Alyssum, Gazania splendens, Lobelia speciosa, Tropæolum elegans, &c. I have begun in time no doubt, but there is nothing like being in time when you can see a chance before you. The Verbenas were put in on New Year's-day, now they are all well rooted, are growing like weeds, and ready for hardening-off by degrees.—J. B. C. F.

PLANTING AND TRIMMING HOLLY AND OTHER EVERGREEN HEDGES.

LADY GEORGINA OAKLEY would be glad if the Editors would answer the following questions:—1, What is the best time to plant a Holly hedge? 2, What is the best time to trim a Holly hedge, old and overgrown? 3, What is the best time to trim a Laurel hedge, old and overgrown? 4, Can old Laurustinuses be moved with safety, which have been kept low, having formed a thick hedge?—*Lisburne House*.

[The best time to plant a Holly hedge in most parts of England is the last week in August and the first week in September, or as soon after as the first heavy rain occurs subsequently to the heat of August. If the rain poured down in torrents any time after the 20th of August, we would begin planting Hollies, Laurustinuses, Portugal Laurels, and such difficult evergreens, and we would wait for the rain till the 20th of September, but no longer. The next best time to move Hollies under 10 feet in height, and Laurustinuses under 5 feet high, is the last fortnight of May, and the first fortnight of June. Any day, however, from the 20th of May to the 20th of August is far better for removing large evergreens than any day from the end of October to the end of April.

The middle of April is the best time to trim a Holly hedge, but the middle of May is better for trimming a hedge of Laurustinus. All other evergreens are better trimmed between the middle of April and the middle of May, and again to have "a look-over" in July.

Old Laurustinuses are difficult to move, but you have no need to fear, as you have a certainty of success if you order the old plants in the old hedge to have the roots cut down on both sides of the hedge any time in April—say to open a trench on each side of the hedge as if for lifting the plants, and after cutting all the side shoots straight down to fill-in the trenches. A mass of fibrous new roots will take possession of the new soil during the summer, and in the autumn the plants will take up the same, almost as if they were out of plant-tubs and almost as safely. The same treatment is applicable to Hollies. Hedges of common Laurel may be made any time from September to June, but not Portugal Laurel hedges. Under the above treatment you need not entertain the least fears about your Holly and Laurustinus.]

PLANTING PAMPAS GRASS.

WHAT is the best season for transplanting Pampas Grass, and can the transplanting be done safely in the spring?—M. B.

[April is the best month in the year for transplanting large plants of the Pampas Grass, and the middle of May is the best time to turn Pampas Grass out of pots. Large plants of it are very easy to move—almost as easy as rhubarb plants. They carry very large balls, and the balls are full of roots, and almost as dry in most soils as a pot ball that has received no water for a long time. Removing the largest plant of Pampas Grass in

April is only a question of strength, on account of the weight of the ball, and the difficulty of reducing it by reason of the number and tenacity of the roots. Nine out of ten Pampas Grass plants in the three kingdoms which are over three years old from the planting-out, stand now very much in need of transplanting, in order to give free scope and fair pasturage to the roots. Every large Pampas Grass plant that is to be removed in April—say after the middle of the month, ought to receive three thorough waterings during the three weeks preceding the operation, and a thorough watering to a full-grown Pampas Grass means from twelve to thirty gallons of clear soft pond water.

The hole for a large Pampas Grass plant should be 1 foot wider than the well-moistened ball to be inserted in it, and should be filled in with the richest and most permanent compost that can be made.

The best Pampas Grass we have seen had forty gallons a-week of strong liquid manure from the first appearance of the flower-stems till all the flowers were at their full prime. From that plant, and from what passed under our own eyes, this notice is written.]

JUNIPER HEDGE.

I AM courteously reminded by a correspondent from Ireland that in the list of plants given, some time ago, as suitable for hedges, the Juniper was omitted. I hope to hear of other cases where plants not named in my list are found to make either useful or ornamental hedges, and I feel more obliged than otherwise to those who can correct any imperfection in my communication.

That the common upright Juniper, as our correspondent says, makes both a pretty-looking and a useful hedge, I verily believe. I have seen the Italian Juniper somewhere planted in a row, and looking remarkably well; but I do not remember seeing the common Juniper so treated.

I believe the kind alluded to by Mr. Beckett, the gardener to Lord Lismore, Shanbally Castle, Ireland, to be one of the improved varieties of the common kind growing wild on dry, hilly places, where the Heath, Furze, and Savin are found; but it is much less commonly met with than they are, and seems to recede more quickly before cultivation than many plants. I have no doubt, however, but with the advantage of a better soil it grows freely as a hedge plant.

Perhaps Mr. Beckett will be kind enough to inform us how Pinuses do in general in the more humid climate of Ireland. I should expect the Silver Fir section, as *Picea Webbiana*, and others might, perhaps, do well there; with us they are less satisfactory. The *Taxodiums* are also likely to grow well in Ireland. Communication from the sister island is at all times acceptable, and I hope we may often be favoured with notices of plants which are either in an unusual condition of luxuriance or the contrary, for both are equally interesting and instructive, as well as all other information on horticulture and its kindred arts.—J. ROESON.

SUCCESSION OF PEAS.

If "D." of Deal will sow his succession Peas throughout the summer, of Sangster's No. 1, he may enjoy that Pea both as an early and late variety. He must be aware that Daniel O'Rourke is the same variety as Sangster's No. 1.—W. G., *The Gardens, Cubyean Castle*.

[We think this is not the information "D." of Deal needs, for no one would like to have a continued repetition of Sangster's No. 1. It is a very good early Pea, but its flavour will not bear comparison with that of later varieties. "D." of Deal we think would like to know when to sow the better-flavoured varieties, such as *Champion of England*, *Ne Plus Ultra*, &c., so as to have an uninterrupted succession.—EDS. J. OF H.]

INFLUENCE OF A LIMEKILN ON GROWING POTATOES.

Do you consider the proximity of limekilns to a field of Potatoes would be likely to have an injurious effect upon the crop?

Persons in the neighbourhood have observed that those growing near the kilns have been healthier and finer than others at a

distance under precisely similar cultivation; and feeling interested in the question from the probability of some kilns being erected near my ground, I should feel grateful for your opinion on the subject.—A KENTISH SUBSCRIBER.

[The observation you quote is really an answer to your inquiry. The volumes of gas and vapour given out by chalk in the process of converting it into lime by the limekiln are chiefly steam and carbonic acid, both of which are more likely to prove beneficial than injurious to Potatoes, and, indeed, to any other crop. So far is carbonic acid gas from being injurious to plants, that it has been found to be beneficial though amounting to one-twelfth of the air in which they were growing. In the calmest day the air over a field surrounded by limekilns would not contain one-hundredth part of carbonic acid gas.—EDS. J. OF H.]

WORK FOR THE WEEK.

KITCHEN GARDEN.

CONTINUE to prepare ground as directed last week. If any part of the garden is not drained, drain it effectually. Make drains 3 feet deep and 18 feet apart. Use tiles and soles, and place 6 inches of brickbats, stones, or rubble over the tiles. Shake a small quantity of litter over the stones or other material before filling in the soil, which will render the drainage more perfect. *Cauliflowers*, give air freely to the plants in frames or under hand-lights. *Mustard and Cress*, keep up a regular succession, and sow Rape when such is required for salading. *Peas*, when the weather will permit draw a little earth to the stems of the early crop, and if cold bleak weather prevails, they will be benefited by the shelter of a few spruce fir branches on the windy side. *Radishes*, those on banks or borders will require strict attention, the coverings to be removed every fine day, and dry soil, charred refuse, or dry wood ashes strewn amongst them for the prevention of damp, mildew, or shanking. *Sea-kale* and *Rhubarb*, keep up a succession either by covering with pots and fermenting material, or by planting in pots and placing them under stages in the greenhouse or stove, the latter being the least trouble—a great consideration in the busy time which is approaching. Continue surface-stirring, and watch opportunities for the destruction of slugs, which if not kept under will soon destroy the labour of weeks. Look over previous directions, and endeavour to bring up arrears. *Basil* and *Margoram*, sow small quantities in heat where such are required green.

FLOWER GARDEN.

Proceed as rapidly as the weather will permit with the removal and planting of large shrubs. Layering may now be successfully performed where the plants have become bare and unsightly at the bottom. Finish the planting of Box-edgings, and fill up all gaps in the old ones. For the destruction of worms on lawns the following receipt is recommended:—Take 1 ounce of corrosive sublimate, pound it fine, dissolve it in sixteen gallons of water, then with a watering-can and a fine rose water the turf infected, when they will soon appear on the surface and can be gathered-up and removed. Prepare beds for Pinks, Carnations, and Pansies. Look over the Dahlias, and remove all decayed portions from the stems and roots.

FRUIT GARDEN.

Planting in every part both against walls and in the open quarters should be completed without delay. Mulch the newly-planted trees, and stake those requiring it at once. Where Filbert trees are kept dwarf, which is the best method of cultivating them, remove all suckers and fork-in some manure about the roots. Shorten all the shoots of last year's growth, but do not interfere with the small shoots, which are the productive ones. Thin out the wood if crowded.

GREENHOUSE AND CONSERVATORY.

Established plants in the conservatory should about this time have the mould well stirred in the pots. Every plant to be kept free from decayed foliage and fading blossoms, with frequent movings and removings from the forcing and other structures, in order to maintain health and gaiety. Place suitable trellises to the *Tropæolums* that are not already furnished, laying a good foundation by furnishing the bottom of the trellis wall. The varieties of *Kennedya*, *Zichya*, *Hardenbergia*, *Gompholobium*, &c., should all have suitable trellises and early training. Water Heaths with care; air freely night and day if the weather is at all favourable. Be cautious with fire heat; even when frost occurs it must be moderate. Stop the strong shoots of

the free-growing varieties, and always keep the dead flowers cleared-off. Any compact plants of Scarlet Geraniums which are intended as specimen plants for vases, baskets, or single specimens on the lawn or terrace during the summer to be now shaken out of their pots and repotted, using turfy soil with a little leaf mould, old cowdung, and sand. Give them, if possible, a gentle bottom heat for ten days or a fortnight, until they make fresh roots, and keep a moderately moist atmospheric temperature of from 50° to 55°. When they have made fresh growth remove to a light, airy part of the greenhouse. Repot them into larger pots or tubs towards the end of March. The Fuchsias should now be looked to without delay. Where fine specimen plants are required, shake the old plants out, reduce the roots, and repot them. Introduce them to a forcing-house at a temperature of about 60°, and as soon as you can obtain cuttings an inch long, strike them in pans of sand kept damp. When struck to be potted into small pots in a compost of turfy sandy loam, turfy peat, and leaf mould, and some sand, and to be shifted into larger pots, as they require to be grown in a warm moist atmosphere, remembering that if you want large plants they must be grown to a considerable size before they show bloom.

FORCING-PIT.

Syringe freely. Continue a kindly humidity. Apply air in suitable weather, taking advantage of those occasions to apply more fire heat. Be very cautious in the application of fire heat at night, or many varieties of plants will prove abortive.

PITS AND FRAMES.

Give plenty of light and air to these structures in fine weather. Look over the plants frequently, and pick-off all decayed leaves. Pot-off the autumn-struck cuttings of Scarlet and Ivy-leaved Geraniums, Fuchsias, Verbenas, shrubby Calceolarias, &c., that are still in the cutting-pans or pots; to be then placed in a gentle heat till they are well rooted. Make a hotbed for cuttings and seeds with fermented dung well-sweetened. W. KEANE.

DOINGS OF THE LAST WEEK.

ROUTINE much the same as the previous week. Wheeling, trenching, turning over ridges, &c., in crispy mornings; pruning, nailing, tying, &c., in fine days; potting, turning soil in sheds, making stakes, tallies, &c., when wet and sloppy.

KITCHEN GARDEN.

Sowed Sangster's No. 1, Dickson's Favourite, and Jeyes' Conqueror Pea, for second crops. Will sow for the first out-of-doors crop three weeks or a month hence, in boxes, to be transplanted. Sowed Tom Thumb and Bishop's Dwarf in boxes under protection, to be transplanted under fences, to succeed those that will have a little glass protection. Stirred the surface soil among those in rows and pots, and the same among Lettuces, Radishes, Parsley, Cabbages, &c. Sowed Carrots, Radishes, and a few Cauliflowers in a slight hotbed of leaves. If Lettuces and Cabbages are likely to be scarce, a pinch sown now in such a mild heat, and hardened-off by degrees, will come in only a very little behind those sown in autumn, and they always seem to eat rather crisper and sweeter. In sowing such a bed of Carrots, we sometimes throw the seed broadcast, and at other times, and perhaps it is the best way, we sow such kinds as Early Dutch and Early Horn in rows about 5 inches apart, and the Radishes and Cauliflower between. The thinning and drawing of the first give room to the Cauliflowers, and when these are pricked out under cover of a mat at night, there will be plenty of room for the Carrots. Potted, also, in four and five-inch pots a number of plants of Cauliflower, and set them where they could have protection, and they will come in useful if we should have severe frost in spring. Put more Asparagus into a slight hotbed, and placed more Rhubarb and Sea-kale in the Mushroom-house.

Swept over all the Mushroom-beds; and as a few woodlice appeared notwithstanding our care, poured some water, nearly boiling, down by the sides of the bed, where they would be sure to lodge after the sweeping. If the water is thus poured from a small spout it will penetrate the bed very little. In addition to this, when the woodlice become numerous, we place small pots with a piece of carrot or turnip in them, and filled lightly with dry hay or moss, and turn the vermin into hot water in the morning. Since we have taken to smoke the house with sulphur in the autumn, we have been troubled very little with woodlice; but a few are apt to come in with the manure material. Potted Dwarf Kidney Beans out of a box, sowed more, and moved

Potatoes in pots into a colder place under glass. Potted Cucumbers in a small dung-frame, as we do not yet wish to use fire heat for them, and for raising young plants nothing after all beats a bed of sweet decomposing material. When the necessary material, and time and care can be commanded, no sort of heat suits them and Melons better. We have cut better fruit of the latter in the end of April from frames than ever we did with hot water; but then the plants never had the chance of suffering from a chill, and the banks of fermenting material that came in afterwards as enriching composts would do our eyes good to look at now. We suspect the fine new improvements that in some places are keeping everything but the distant scent of manure from the gardens, will perforce secure sweet vegetables, if they should be small. A good many of us could not grow them rank if we tried.

FRUIT GARDEN.

Pruned and nailed common trees as opportunity offered, leaving Apricots and Peaches alone, but loose-nailed to let the air about them, and to prevent the trees becoming heated from contact with the wall in such a sunny day as we had on the 28th ult. Have not pruned any Gooseberries yet, as we did it too soon last year. Feel almost disposed to let them alone until the fruit shows, the birds getting at ours with all our care last year. The weather has as yet been too mild to tempt birds much. Will syringe the bushes with a mixture of lime, clay and soot, the bitterness of which will tend to keep birds away as the buds swell. Just inserted the points of a fork between the rows of Strawberries to keep the dung, &c., on the surface loose, and let the rains pass freely through them, pressing the rich soil to any buds that seemed to stand naked or higher than the rest. We have long found that Strawberry plants will stand much cold if there is little or none of the stem exposed below the buds. Two years ago we were asked to look at a plantation of Strawberry plants, which though seemingly strong produced nothing but leaves. We noticed that the plants if separated might have been taken for little dwarf standards, so long and naked were their stems; and to the effect on them of a severe frost, and watering late in autumn with very rich liquid manure, we attributed the ruin of the flower-buds. At any rate, another plantation in a neighbouring garden, of the same kind of Strawberry and planted at the same time, which had received no such treatment, presented no similar appearance, and was a mass of bloom and swelling fruit.

Forward Strawberries in-doors will need more water as the fruit is swelling, but to be given moderately in such dull weather. Those freshly placed in the house should be kept rather dry before the bud is seen moving, and even then rather dry instead of wet until the flowers are expanding. Those in bloom should have a feather or a dry hand waved through them to disperse the pollen. We are obliged for the thanks sent by several, as to not allowing water to stand in saucers during the early stages of the forcing of Strawberries, and some correspondents wish to know if there is nothing else that would do as well as moss for setting the plants on, as they have a difficulty in obtaining it, and it blows so about. We have often used, because we could not help ourselves, thin pieces of turf—say 6 or 7 inches wide and 1 inch thick—placed on the shelf with the grass side downwards. The pots were set level on the earth side, and to secure that level a little leaf mould was scattered along. This secured a moist bottom, and the plants could not be overwatered except by the grossest carelessness. We were rather pleased the other day in a princely establishment, where they had splendid shelves on purpose for Strawberries, with edgings an inch deep and lined with lead and pitch to retain water, to find that the most of the Strawberry-pots, except those fruiting, were either standing on bare shelves, or on temporary shelves covered with thin turves. One side of a long span-house had a stage thus formed; bricks set on the bed supported the upper shelves and their line of turf, and the plants looked extremely well and promising. Our friend in pointing to the shelves said nothing, but the look just spoke thus—"There! if we have such abundant means we don't despise the simplicities." For a swelling fruit nothing can be better than these edged shelves, but the danger is, with careless watering, that the plants at an early stage are apt to become too wet, just as they are liable to do when set in saucers. Last year an amateur asked us to look at his Strawberry plants in pots, they should have just been coming into bloom, but scarcely a bloom opened kindly or showed farina on the stamens, and there need have been no wonder, for though there had been a

week of dull weather the saucers were filled up to the brim every morning, and thus the Strawberry was made a marsh plant. In such circumstances of the plants a good rain out of doors would most likely have secured a fine crop; but then that rain passed beyond the roots and did not stand stagnant around them.

Looked over Strawberry plants in orchard-house to see that they did not become too dry. The house being a lean-to, had the Peach trees against the wall untied well washed with soap and water, and when dry painted with sulphur and clay, putting about 3 ounces to the gallon of Gishurst in it. The wall was then washed with fresh lime paint, darkened sufficiently to a dull colour with lampblack, as in such a house the reflection of light and heat from a very white wall would have been too much, especially when the trees were in bloom. In such lean-to houses used as vineries, the Vines being taken up the rafters, a much whiter or lighter colour may be used. When, however, in such a house, we have used the back wall from top to bottom for shelves, we have frequently given such a wall two washings—first a dull white as above for the early part of the season, that the plants near the wall should not suffer; and then a lighter colour in summer after the leaves of the Vines had fully expanded, but keeping air on for several nights afterwards, in order that all the light possible should be thrown back from such a wall, so as to benefit the Vines in general, and any plants on the floor, or on the stage, in particular. Amateurs with their one lean-to may thus see the importance of not having their back wall too bright in spring if they grow plants against it, and the equal importance of not having that wall covered with dirt and green slime as the autumn approaches. See late notice on "The Science and Practice of Gardening." We mention these little matters more prominently because we are all apt to take to gardening by fits and starts, and if this can be laid to the charge of us professionals, we fear the fault would be found more general amongst amateurs and cottagers. What a difference often in the little houses of the former in spring and autumn, not to speak of the lumber-room appearance in winter; and what a change from the trim garden of the cottager in April and May, and the weeds and decay and wretchedness too often seen in September and October. We recollect once that a company of gardeners expressed an earnest hope that the late Mr. Loudon would not take a tour among certain gardens in the autumn, as they were sure the masses of rotting decayed pea-haulm, and decaying and rotting vegetables, would furnish him with a whip for satire, which would be all the more keen because it was felt to be true and well-deserved.

Went on with forcing very gradually, as detailed last week, keeping the Peach-house from 45° to 50° at night, and 50° or a few degrees more in dull days, with a rise in sunshine to from 60° to 70°, with plenty of air, shutting-up early in the afternoon, and if sun heat can be enclosed, giving little or no fire on mild nights. Earliest vinery averaging 50° at night, buds beginning to swell. Vine-pit, a small place, buds breaking, from 55° to 60° at night. Some Vines in pots that had little but a cool orchard-house to grow in, are showing very fair, though I did not think the wood quite hardy enough for early work. Small Fig-house being full of plants is kept from 40° to 45° at night. All fruit trees in pots out of doors and in-doors in open, cool houses, such as orchard-houses, are plunged in stubble. This has not been necessary this season, as yet; but it is of little use protecting a pot when the soil is as hard as a brick. Giving air has required much nicety, not so much owing to cold, as to the force of the gales, which necessitated the pinning and fixing of sashes to make all secure.

PLANT DEPARTMENT.

Of this we have room to say so little that we must refer back to previous weeks for details, merely stating that walks were swept, and lawns rolled, a few more ashes put on Hollyhock crowns to send the water past, Pansies and Pinks and Carnations firmed, &c. A little dry soil or leaf mould should be ready, for putting as little cones over forward Tulips, if a severe frost should come; ditto as respects Hyacinths; and the surface of the ground intended for Ranunculuses and Anemones should be aired. Plant-pots were watered, cleaned, and arrangements made for having lots of cuttings put in—such as Verbenas, Geraniums, &c. In the grand establishment referred to above, the foreman took us to see a cold pit of Calceolarias, which seemed to have been done exactly as we described our own to have been done in the autumn. Although not a word was said to that effect, we could see at a glance that there was a

little rivalry about these Calceolarias among the young men, and we must own that they were in most excellent condition, and becoming fine strong plants for Mrs. Bird to lift and pot, or for our friend to transplant where he could give them good treatment, as houses and pits seem to rise whenever Fortunatus chooses to put the wishing-cap on. We would even say that the plants are, perhaps, a little better than our own; but as we do not wish ours to hurt themselves with crowding, for more than a month to come, we are rather more satisfied with them than if they had been stronger. We shall also, in three weeks or so, take a few cuttings off the points, as last year we felt the want of some small plants for outside.—R. F.

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

EVERGREEN FLOWERING SHRUBS FOR PALING (*G. K., Sevenoaks*).—Properly speaking, there are no wall, or espalier, or fence evergreen flowering plants. The *Escallonia macrantha* is only a conservative wall plant—that is to say, not sufficiently hardy for all places and all winters in Kent. For a garden paling 4½ feet high, a row of bush plants is all that is needed; and the two best evergreens with good flowers for the style of fence are *Berberis Darwinii* and *ilicifolia*. A hedge of *Cotoneaster microphylla*, kept to the height of your paling, is one of the most beautiful hedges we have ever seen when loaded with its coral berries.

COCOA-NUT REFUSE DUST (*W. H. F.*).—For all pot plants except Ferns and a few very rare plants and bulbs, use the same quantity of this refuse dust as the usual quantity of peat, leaf mould, and sand. The dust supplies the place of sand, leaf mould, and peat in general composts.

GUANO (*W. S.*).—From two to three hundredweight per acre is the proper quantity, the larger quantity being for a soil more than usually impoverished. It is most beneficial on retentive soils.

WATERING ROSES (*A Subscriber*).—Mr. Rivers says the best manure for Roses is three good substantial brown soakings of manure water during the winter months, while the Roses are at rest, and he ought to know what is best for Roses. Your gardener followed his advice.

FINE-FOLIAGED PLANTS FOR A GREENHOUSE (*Idem*).—There is no such thing as a greenhouse class of fine-foliaged plants. All such are now used out of doors in beds and borders during the summer months; and most of the stove fine-foliaged plants do better in the greenhouse, while the badders are out of the greenhouse, than by being kept more close than in a stove, and not so much confined.

BRITISH WATER LILIES (*L. T. V.*).—From the middle of March to the middle of April is the best time to plant the native Water Lilies; but February, or any time during the winter would do. The best way to do the work would be to procure large lumps of the roots with the soil attached, then their own weight would keep them down. The next best way would be merely to take so many of the fleshy roots and fix them in the mud, or, if the mud were too loose, to put thick lumps of turf from a clay ground over them, or, rather, to stick the roots in the turf first, and then place them in the pond. Eighteen inches of water would be deep enough to grow them; but we have had them in water much deeper, and in summer we have had them in a less depth for months and doing well.

GRAFTING ROSES (*J. J. Smyth*).—It is too soon yet to begin to graft Roses on Manetti stocks, unless you have a hot propagating-house to put them into. Mr. Beaton told us the other day he intended to graft Roses in February; but for ourselves, we should think the first week in March about the best time. In the nurseries, they have been grafting Roses since October in their hothouses. The best "liquid that causes cuttings dressed with it to throw-out roots," is rain water collected in shallow ponds at the lower corner of rich meadow land; and the best liquid to cause Vines to root is the same pond water, with gallon for gallon from a deep horsepond, into which the drainage of a farmyard is allowed to run.

ATRIPLEX HORTENSIS RUBRA AS AN EDGING (*R. W.*).—The Purple Orach plant that is used for flower-beds is *Atriplex hortensis rubra* of the catalogues, and is now to be had true almost everywhere. Most people train it down and nibble it to keep it to the proper height, but that is not the best way. The true mode of proceeding is to plant two rows of it 4 inches asunder, to make one row or line, and when it is 6 inches high to pinch-out the tops; after that to pinch-out at every second joint of new shoots, also to pluck-off every leaf as soon as it becomes rusty, which makes constant room for a succession of new leaves. We had it that way all last summer as fresh in September as at the end of May, and quite as low, without a single row being bent or trained.

ARGENTEA (*Idem*).—Argentea is only a second name in plant nomenclature, and there are a hundred kinds of argentea. The plant you mean is rather a nice plant, and the name of it is *Centaurea ragusina*; it is not better than *Cineraria maritima*. The one called *candidissima* is the finest *Centaurea*, but is dearer.

WEEDS ON LAWN (C. B.).—There is no way of destroying "Wild Marjoram," or creeping Buttercup, or Daisy, or Plantain, or any other weed on a lawn except by hand-picking, or unturfing the parts and relaying with better turf, although close and constant mowing does much towards exterminating them.

FUCHSIA SEEDLINGS (Christine).—Your Fuchsia seedlings are not hybrids, unless you had them between two wild kinds called species; they are cross-bred varieties by crossing two seedling varieties in-and-in, as all improvements in florists' flowers are obtained. Of course they will be such as you never saw before, just like our own seedlings, but better may have been already in the field; but no one can believe that of a seedling until the seedling itself proves it one way or the other. Your dwarf seedling, with the developed red leaves, is the most fashionable of them all. It intends to be a foliaged plant like Meteor, with which the Messrs. Carter made half a fortune last year; so you must look to it in earnest, but do not hurry it.

BOOK ON CONIFERÆ (T. Malcomson).—There is none better than Gordon's, "The Pinetum." It is published by Bohn, and, with its Supplement, includes information on the species known down to last year.

GARDENER'S EDUCATION.—The first part of "A YOUNG GARDENER'S" question Mr. Fish will attend to as soon as possible, but the question of lodgings has two sides. Where many young men are kept in a bothy, it tends to increase the number of gardeners, and the number is already too great for the demand. You would see the whole philosophy of the proceeding treated by Mr. Fish some years ago. The same nurseryman alluded to there has written the other day saying, "Oh, for a weeding-out!" The matter most likely will be taken up with other collateral subjects ere long. To those not answered privately, and who want good men at very low wages, Mr. Fish would refer them to some remarks made last year when describing the small garden of Dr. Neligan, at Blackrock, near Dublin. To see the full drift of his argument that article, and the one above on "attention," &c., should be read together. It was the least of his intentions, when recommending "attention," &c., to further the idea that a good gardener was to be had for so many shillings per week.

WEIGHT OF GRAPE AND STRAWBERRY CROPS (G.).—We once made a memorandum of such matters, but cannot now find it, and without it we would rather not answer the query, and more especially as such questions are seldom made except to serve a purpose. But for that, we would say 3 to 4 lbs. of Grapes in good-sized pots, and well done, and from 2½ to 3 ozs. of Strawberries. We have had much less, and in some fine pots much more.

MANURING STRAWBERRIES (A Subscriber).—If your plantation is in rows 2½ feet apart, a coating of well-rotted dung might be laid on the space between, and very slightly forked-in, not allowing the fork of the operator to descend more than 3 inches at the utmost. If this does not bury the dung, spread a little fresh mould on the surface, and the result will be satisfactory. It is better not to cut the leaves much, as they shelter the crowns. The leaves will die down when they are no longer wanted.

GERANIUM HELEN LINDSAY (Leaves).—We also want to know where Helen Lindsay, the new Lobelia's, and the other fine seedlings mentioned in our pages are to be had. But we must wait the dealers' time, and learn from the advertisements. We do not know of any new Lobelia which we have not described already, and until they are announced for sale we do not know where to look for them.

PEAT CHARCOAL (G. C.).—There was a manufactory near London, but we suppose it no longer exists, as we never see its advertisements. Write for information to "The London Manure Company," Bishopsgate Street.

NAMES OF PLANTS (R. F.).—1, *Asplenium trichomanes*; 2, *Pteris tremula*; 3, *Asplenium marinum*; 4, specimen insufficient; 5, *Lastrea filix-mas*; 6, *Cyrtomium falcatum*; 7, *Pteris bastata*; 8, *Doodia caudata*. All *Adiantums* are Maiden-hairs, and all Maiden-hairs are *Adiantums*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHO WILL BE WINNERS IN 1863?

MURPHY made a hit when he predicted the hard weather. It is said that the respected "Francis Moore, physician," who was supposed to preside over the compilation of a certain "Vox Stellarum," or "Loyal Almanack," published annually by the Stationers' Company, came into note, and was made by the fact that in a fit of ill-temper he predicted snow for the 1st of June, and there was snow. The almanac also gave an annual hieroglyphic. It was generally made up of a crown, coffin, and dragon. This sort of thing did for the dreamy times, when people travelled in coaches, and paid 2s. for a letter; but it is different now. Were it not that now and then a bad wife calls in a "cunning woman" to know how much longer the old man will live; or the frightened and half-repentant housemaid goes to the "clever man" to know when her "young man" will return the plate she lent him, and also whether he will surely marry her, we should say the days of predictions were passed. But we forgot the turf prophets—Vates, Agrippa, Sphinx, Oracle, Jones's Boy, the Lucky Baker & Company, who for the small "tip" of thirty postage stamps, will unveil the future in *re* racing, and tell you all the winners of all the great stakes. It was remarked of old, and we suppose it is true now, that he who can make the fortunes of others is generally poor himself.

Undeterred by that fact we assume the character of the "wise man," and we pierce the dark future, venturing to predict, even at this early time, the principal winners in the poultry world for 1863. "Ladies and gentlemen, make your game."

Some of our readers will recollect the days of lotteries. "Five of 30,000, six of 10,000, and all prizes and no blanks." The latter signifying that by investing £32 you were sure to win (P) a sum not less than £1! Nothing was beyond the capability of a ticket in the lottery. Only dream of a lucky number, or come in contact with it, and you were sure to win. We knew a man in a froat who slipped, and broke his leg opposite 311, Oxford Street. He bought a share of the number, and received guineas for pounds. You had only to buy a ticket, and then, if

"You'd portion a daughter in marriage,
Or live independent and free,
If you'd set up in trade, keep your carriage,
Or a member of parliament be,"

why, the ticket would do it. The ticket must be bought before the drawing. In lotteries, as in everything else, numbers of people knew the winning number after it was made public; but they kept their knowledge quiet till then.

Our prediction is, that poultry as an article of consumption will be dear this year, and they will be the winners who set about rearing and feeding their chickens now for April and May. We promise prizes to all those who in those two months shall provide and fatten chickens of the year to the weight of 3 lbs., or 3½ lbs. This is the neglected part of the poultry fancy, and we are aware we are wont to harp upon it.

We shall return to it. Our motive for beginning thus early is, that *now* is the time when the chickens must be hatched, or, at any rate, the eggs put under the hens.

NO ONE SHOULD BE AN EXHIBITOR AND JUDGE AT THE SAME SHOW.

In looking over your Journal of Tuesday last I find a list of awards at the Liverpool Poultry Show, also the names of the Judges. I find Mr. R. Teebay, of Fulwood, near Preston, as a Judge for poultry; also a Mr. R. Teebay that has taken the silver cup for Spanish fowls, also first and second for Brahma Pootras. It is quite a new idea to see a person acting as Judge and exhibiting at one time at the same Show. I consider Mr. Teebay would have been in his proper place as a Judge or an exhibitor, but not both at one time.

I am not accusing any one of unfairness or partiality, but I think it looks very bad for any exhibitor to be in the same room at the same time that the Judges are awarding the prizes.—AN EXHIBITOR.

[We noticed the fact mentioned by our correspondent, and thought it a great error on the part of the Committee. No charge is brought against Mr. Teebay, and he was Judge only of classes in which he was not an exhibitor, yet he was in the room while those classes were being judged in which he did exhibit, which ought never to be permitted. It gives rise to suspicions which are injurious to all parties.—EDS. J. OF H.]

WORCESTERSHIRE POULTRY AND PIGEON SHOW.

THE announcement of this Show, which is in our advertising columns to-day, is very satisfactory. It is to be held in grounds adjoining to and on the same days (July 20th–24th) as the Royal Agricultural Society holds its Exhibition at Worcester. The prizes are liberal, and we have no doubt the Show will be well supported.

SILVER-GREY DORKINGS.

ANOTHER breeder of Silver-Grey Dorkings, and one who has been well known as one of the largest and most successful exhibitors in that class, begs leave to indorse the Editors' opinion as to the impossibility of Silver-Grey Dorkings keeping pure in colour after the first moult. Take, for instance the statement of "ANOTHER BREEDER OF SILVER-GREYS," that the hens should be pure Silver-Grey, as free from brown on the wings as may be; the breast salmon colour, not, as is too frequently the case even in winning pens, with one hen, or sometimes both, with breasts nearer approaching to a brownish-white. His own words prove the difficulty there is in obtaining a pen of Silver-Greys pure in colour. I also beg to say I have been to most of our poultry exhibitions that have been held this past season, and yet have

not seen one adult pure-coloured pen shown. This proves how difficult it would be for judges to find pens sufficient to give three prizes in one class if they were to judge to a defined standard, such as "ANOTHER BREEDER" species; and such points we well know they ought to have to make a pure Silver colour.

My own experience is, that nine out of ten lose the nice Silver-Grey colour in the body and wings, or the hackle acquires a mealy-smoky colour, and then all the beauty of the Silver is gone.

Another proof is, that one of our most successful yards could not send one adult pen to any exhibition this last season. I must say it would be a paying affair to poultry committees to have the Silver-Greys judged by a defined standard, for how few of the prizes would be awarded!—J. D.

ADVANTAGE OF WARNINGS.

I HAVE not only derived much pleasure from the perusal of your Journal, but important instruction in gardening, and in the management of poultry it has considerably aided me in obtaining my present position as "first-prize winner in Ireland." But, above and beyond pleasure and profit, its oft-repeated warnings have saved me from a loss of nearly £8 very recently.

A very pressing order came from Bradford for some of my prize birds, but without a post-office order. I replied civilly that I adopted the English system of prepayment. The application was repeated three times so urgently and so speciously that had it not been for THE JOURNAL OF HORTICULTURE, I should have forwarded my birds.

I thank you very sincerely, and trust you may continue to prosper and increase in favour with the public.—E. D. C. D.

[The Rev. E. Cadogan was not so wary. He informs us that he sent four pullets and a cockerel to Mr. S. Matthews, Beswick, near Manchester, and cannot obtain the money for them, nor any answer to his applications. We can only repeat our astonishment that any reader of our pages can be induced to part with birds to a stranger without prepayment.]

JEDBURGH POULTRY SHOW.

THE annual Show of Poultry, Pigeons, and Canaries was held in the Corn Exchange, Jedburgh, on the 22nd and 23rd January, and was the most successful one ever held there. The entries numbered nearly a hundred pens more than last year, and its promoters now flatter themselves that it is likely to be a permanent Show.

The following gentlemen officiated as Judges:—For *Poultry*: Messrs. J. H. Smith, York, and A. Sutherland, Burnley. *Pigeons*: Mr. G. J. McLean, Edinburgh. *Canaries*: Mr. W. Rell, Edinburgh.

The following are their awards for Poultry and Pigeons:

SPANISH.—First, W. Ridpath, Edinburgh. Second, J. Shorthose, Newcastle. Third, W. Wilson, jun., Beith. Highly Commended, R. Teebay, Fulwood, near Preston; T. Ogilvie, Jedburgh. **CHICKENS.**—First, W. Wilson, jun. Second, W. Ridpath. Third, Mrs. White, Perth. Highly Commended, J. Williamson, Falkland. Commended, J. Shorthose; J. C. Wakefield, Glasgow; W. Sime, Cambus.

DORRINGS.—First, R. M. Stark, Hull. Second, Mrs. Grey, Grantham. Third, J. Stocks, Kirkcaldy. Highly Commended, J. Christie, Prestonkirk; J. Gileson, Dalkeith; Lord Binning, Mellerstain; J. Dixon, Bradford. Commended, Mrs. Dickens, Kelso; Sir J. D. Wauchope, Bart., Dalkeith. **CHICKENS.**—First, J. Stocks. Second, R. C. Nisbet. Third, Miss Milne, Otterburn. Highly Commended, J. Murray; Sir J. D. Wauchope, Bart.; J. C. Wakefield. Commended, Lord Binning. **PULLETS.**—First, J. Stocks. Second, J. Gibson. Third, L. Appleby, Darlington. Highly Commended, Miss Milne; H. W. B. Berwick, Helmsley. Commended, J. Jardine.

COCHIN-CHINA (Any variety).—First, J. C. Wakefield. Second, J. Shorthose. Third, Miss E. A. Aglionby, Wigton. **CHICKENS.**—First, Miss E. A. Aglionby. Second, Miss Milne. Third, H. W. B. Berwick.

BRAHMA POOTRA.—First, R. Teebay. Second, H. W. Scott, Forfar. Third, Miss Purves, Jedburgh.

GAME (Black or Brown Reds).—First, H. M. Julian, Beverley. Second, H. Adams, Beverley. Third, J. Hodgson, Bradford. Highly Commended, W. Easton, Jedburgh; Lord Binning. Commended, J. A. S. E. Fair; J. L. Anderson. (Duckwings).—First, H. Adams. Second, J. Hodgson. Third, J. Smith, Grantham. Highly Commended, D. Brown, Glasgow. **CHICKENS.**—First, Miss J. A. Aykroyd, Bradford. Second, H. Adams. Third, W. Boyes, Beverley. Highly Commended, T. Dodds, Halifax. Commended, J. Gibson; J. Anderson; J. Fiddes; W. Easton.

HAMBURGHS (Silver-spangled).—First, W. Cannan, Bradford. Second, J. C. Wakefield. Third, J. Dixon. (Silver-pencilled).—First, W. Cannan. Second, J. Dixon. Third, J. Robinson, Garstang. (Golden-spangled).—First, W. Cannan. Second, J. Dixon. Third, J. C. Wakefield. Commended, H. W. B. Berwick. (Golden-pencilled).—First, W. Cannan. Second, S. Smith, Halifax. Third, C. W. Brierley. Commended, J. C. Wakefield; J. Ness.

POLANDS.—First, H. Beldon, Bradford. Second, J. Dixon. Third, J. Paul, Glasgow.

BANTAMS (Gold and Silver-laced).—First, Lord Binning. Second, F. L. Roy, Berwickshire. Third, J. Anderson. Highly Commended, J. H. Frame, Overton. (Any other variety).—First, J. G. Park, Whitehaven (Game). Second, E. Hutton, Pudsey (Black). Third, Miss Purves (Game). Highly Commended, J. Anderson; J. Shorthose.

GESE.—First, Lord Binning. Second, J. U. Somner, Jedburgh. Third, Mrs. Bell. Highly Commended, S. Swan, Bush.

DUCKS (Ayle-bury).—First, J. Smith. Second, S. Swan. Third, C. Pease, Darlington. Highly Commended, J. C. Wakefield; A. Dunn; Lord Binning; W. Sime. (Rouen).—First, J. Gibson. Second, Mrs. Elliott, Hyndhope. Third, J. U. Somner. Highly Commended, J. M. Grainger. Commended, Mrs. Elliott. (Black East Indian).—First, J. R. Jessop, Hull. Second, R. M. Stark. Third, F. W. Earle, Prescott. Highly Commended, J. Dixon. (Any other variety).—First, E. Hutton (Wild). Second, Miss Purves (Mallards). Third, J. Patterson (Mallards).

TURKEYS.—First, Mrs. A. Guy. Second, J. Gibson. Third, J. James, Samiaston. **Poults.**—First, Mrs. A. Guy. Second, J. Smith. Third, J. Christie, Hailes. Commended, Mrs. Rutherton, Melrose; J. Jardine, Arkleton. **Hens.**—First, J. Smith. Second, J. Jardine. Third, J. Christie. Commended, Mrs. Guy; J. James.

ANY OTHER VARIETY OF POULTRY.—First, H. Adams (Black Hamburgs). Second, J. A. S. E. Fair (White Dorkings). Third, E. Hutton (Black Hamburgs).

SINGLE COCKS.

SPANISH.—First, W. Wilson. Second, R. Somerville, Edinburgh. Third, S. Corner, Monkswearmouth. Highly Commended, J. Shorthose.

DORKING.—First, R. M. Stark. Second, R. C. Nisbet. Third, J. Stocks. **COCHIN-CHINA.**—First, H. W. B. Berwick. Second, J. Shorthose. Third, J. Macauley, Edinburgh.

GAME.—First, H. Adams. Second, R. Payne, Marsden. Third, H. Beldon. Highly Commended, H. M. Julian; T. Dodds; J. Wilson. Commended, W. Toppin; W. Boyes.

TURKEY.—First, Mrs. A. Guy. Second, J. James. Third, Miss Bell, Cressford. Highly Commended, J. James.

SWEEPSTAKES.

BANTAM COCKS.—First, T. J. Wood, Stockton-on-Tees (Game). Second, S. H. Jeffrey, Jedburgh (Black). Third, C. W. Brierley. Highly Commended, G. J. Harvey. Commended, R. Corbett; A. Henderson.

SELLING CLASS.—First, W. Jeffrey (Game). Second, H. Beldon. Third, D. Murdie, Jedburgh (Spanish). Highly Commended, J. Anderson (Dorkings); C. W. Brierley (Polands); H. M. Julian (Game); J. Scott (Dorkings); Miss Bell (Turkeys); R. Patterson (Dorkings). Commended, J. R. Jessop (East Indian Ducks); R. R. Tulip (Golden-pencilled Hamburgs); J. James (Aylesbury Ducks); W. Scott (Dorkings); J. Smith (Aylesbury Ducks).

COTTAGERS' PRIZES.—First, A. Scott (Dorkings). Second, T. Oliver, Jedburgh (Spanish). Third, T. Climinson, Darlington (Duckwing). Highly Commended, J. Fiddes (Game). Commended, G. Ritchies; J. Sword; R. Sword.

PIGEONS.—*Almond Tumblers.*—First, A. L. Silvester, Birmingham. Second, M. Sanderson, Edinburgh. Third, R. Pickering, Carlisle. Highly Commended, H. Yardley, Birmingham. *Tumblers* (any other variety).—First, J. Bell, Newcastle (Kites). Second, J. H. Frame, Lanark (Red). Third, E. Somner, Kelso (Beards). Highly Commended, Miss Purves. Commended, J. W. Edge, Birmingham. *Fantails.*—First, T. C. Taylor, Middlesbrough. Second, Lord Binning. Third, J. R. Jessop. Highly Commended, W. Veitch, jun., Jedburgh. Commended, T. L. Jackson, Dumfries. (Considered by the Judge a magnificent class). *Pouters.*—First and Second, M. Sanderson. Third, J. H. Frame. Highly Commended, A. Scott. Commended, M. E. Jobling, Newcastle. *Nuns.*—First, W. Veitch, jun. Second, J. Jones, Edinburgh. Third, Lord Binning. Highly Commended, H. Yardley. Commended, J. W. Edge. *Owls.*—First, H. Beldon. Second, M. E. Jobling. Third, F. Key, Beverley. Highly Commended, Lord Binning; H. Yardley. Commended, Miss Purves; A. L. Silvester.

Turbits.—First, Miss Collier, Jedburgh. Second, J. U. Somner. Third, W. B. V. Haasbergen, Newcastle. Highly Commended, J. R. Jessop; T. C. Taylor. Commended, R. Pickering; A. L. Silvester. *Jacobins.*—First, T. Ellington, Woodmansey. Second, F. Key. Third, W. Veitch. Highly Commended, T. Ellington. Commended, H. Yardley. *Any other Variety.*—First, J. H. Frame (Barbs). Second, Lord Binning (Blue Priest). Third, J. R. Jessop (Trumpeters). Highly Commended, J. W. Edge. Commended, A. L. Silvester; T. Rule, Durham; J. Crew, jun., Jedburgh.

SELLING CLASS FOR PIGEONS.—First, W. P. Gray, Kelso (Turbits). Second, H. Beldon. Third, F. Key (Trumpeters). Highly Commended, J. R. Jessop (Archangels); T. Rule (Nuns). Commended, W. P. Gray (Jacobins and Almond Tumblers); M. Sanderson (Magpies).

In the Canary class there were about eighty entries, and the frequent bursts of melody by this band of songsters added materially to the other attractions of the Show.

NATIONAL COLUMBARIAN SOCIETY.

THE Annual Show of this rapidly rising Society was held at Anderton's Hotel, Fleet Street, on the afternoon of Tuesday, January the 27th. The room was so well attended as to be inconveniently crowded during the whole of the Exhibition.

Many of the birds were of very superior quality. The pen of *Almond Tumblers* exhibited by Mr. Jayne, was, in many respects, one of the very best we have seen for some time. In point of colour many were perfect standards, whilst in head and beak they were very superior. Mr. Corker also showed a very superior pen of Almonds. Mr. Smith's show of Black Mottled, Baldheads, and other Short-faced Tumblers was exceedingly creditable.

In *Pouters* the Show was very strong. Mr. Corker exhibited a pair of superior Whites; Mr. Bacchus a large number of very good birds, particularly remarkable for their length of limb and

feather. Mr. Hayne exhibited the same birds that he showed at the Philopisteron Annual Meeting.

In *Carriers* the Show was well represented, but we did not think the birds, as a whole, as good as those comprising the other classes. Mr. Betty, and also Mr. Feltham, showed some very good specimens, but the majority wanted the grace and style that is essential to elegance in stout birds.

In *Barbs* the Show was very strong, Mr. P. Jones and Mr. Johnson exhibiting many very good specimens of all colours—Blacks, Red, Yellow, and Duns. Mr. Morris's pair of White Owls were very good, being very good specimens of the small *petite* African variety that have come into such general favour.

There were also a few good *Turbits* and *Jacobins*. Nor must we forget to mention the Short-faced birds of Mr. Percival that fully maintained his reputation. Mr. Norman exhibited a very singular Owl, evidently bred between an imported White and an English Blue; the bird was somewhat irregularly pied, but would be valuable as improving the form and lessening the size of the ordinary Blues.

As a whole the Show may be described as being very first-rate in Almonds and Pouters, thoroughly good in Barbs, not so strong in stout birds; and, as a whole, deficient in Toys. It was unquestionably the best the Society has ever held. In some classes it ran the Philopisteron Show very close, and the older Society must look to its laurels if it would not lose its pride of place and the proud pre-eminence that it has held so long. At the same time there is plenty of room for the two Societies, each, in its own way tending to the advancement of the fancy—the improvement of the breed of the different varieties.

BELGIAN SMERLES.

In the account of the Philopisteron Society in your Journal for December 2nd, we are informed that "Mr. Tegetmeier appears to be devoting his attention to experiments on the homing faculty of the Belgian Smerles." As no Pigeons of the above name are known in this neighbourhood, several of our "gentlemen of the fancy" would take it as a favour if Mr. Tegetmeier would give us a detailed description of the features by which these Pigeons may be distinguished from others, and how they are supposed to be bred.—J. PARKER, *Burnley*.

[In reply to the inquiry of Mr. Parker, I will, in preference to giving my own description, translate some passages from a letter received from Mons. A. Lejuene, the editor of *Le Pigeon*, the weekly journal of the flying fanciers of Belgium.

Mons. Lejuene writes as follows:—"Smerles, the Short-faced Pigeons of the province of Liège, are remarkable for their sagacity, for the size of their heads, and the beautiful structure of their wings. At the age of two years they perform the distance from Bordeaux to Verviers in twelve hours, provided the sky is clear and the wind favourable, in bad weather returning the following day or the day after.

"The journeys of 150 leagues, as from Tours, Poitiers, and Châtelleraut are performed in eight hours." It may render this account more readily appreciated if I state that the exact distance from Tours to Verviers, in a straight line is 330 English miles, Châtelleraut being 365, and Poitiers 380 miles from the same place. These statements, it should be remembered, are not made at random, but express the rate of speed at which the great flying matches of the Belgian fanciers are performed.

The value placed on good birds of this variety in Belgium is shown by the continuation of Mons. Lejuene's letter, he says:—"A couple of young Smerles of choice quality and warranted bred from birds that have been proved, sell for 100 francs. Old birds fit for breeding, that have made long voyages, sell for 70 to 80 francs each; and a Pigeon that has carried off several prizes will even sell for 500 francs." In reply to the latter part of the inquiry, I would state that these birds are smaller than ordinary Dragons, of various colours, the most prevalent being Blue Chequers and Meales. The formation of the head in some strains resembles that of the variety known as "Owls," but the beak is not so short, though in all cases it is stouter than that of a common Blue Rock Pigeon. The great distinguishing peculiarity of these birds is the extreme breadth of the flight-feathers of the wings, the depth of the keel of the breast-bone, and size of the muscles which move the wings: consequently their rate of speed is extreme, and their powers of flight remarkable.

I do not know any more beautiful sight than to see a dozen of these birds dash off in the gales that have been so frequent,

and, after permitting themselves to be swept far away by the violence of the wind, return in the very teeth of the hurricane, with apparently as great a degree of quickness and ease, as though the atmosphere were a perfect calm.—W. B. TEGETMEIER, *Muswell Hill*.

EARLY POLLEN-GATHERING.

THIS day (29th January) the temperature is quite as genial and balmy as in a warm day in spring; as I write the sun is shining brilliantly, and all my bee-hives are in full activity. Pollen is being carried freely into most of them, and the scene so vividly described by Herr Braun, a translation of whose verses will appear next week, is being re-enacted with the utmost vigour in the garden of—A DEVONSHIRE BEE-KEEPER.

BEE BOTTLE-FEEDER.

If your intelligent and amusing Oxfordshire correspondent would only condescend to give the inverted bottle a fair trial, he would but act up to the spirit of the cognomen he has assumed, by making an immense stride, both upwards and onwards, in practical bee-keeping. Let him but once do this, and I feel certain that the very next Number of THE JOURNAL OF HORTICULTURE will contain, for the benefit of the million, full particulars from his pen of how to make a bee-feeder entirely without cost (for who but possesses an otherwise useless empty bottle?), and far superior to all others in every respect both for autumn and spring feeding.

A graphic relation of the circumstances attending the consignment of all his "drum-feeders" to the kitchen fire, and his "zinc-feeders" of every description to the melting-pot, might probably and most fitly conclude an article which would prove that in apian matters his *nom de plume* has some foundation in—TRUTH.

BEE MOTH TRAP.—Take a wooden bucket or other large open vessel, and fill it about two-thirds with water. Then put in a quantity of old honeycombs and set the vessel in the apiary, at night, near the hives. The bee moths or millers will be attracted by the strong odour arising from the vessel, and after hovering over it a while, will drop into the water and be unable to extricate themselves.—(*Bee Journal*.)

OUR LETTER BOX.

BLACK HAMBURGS (B.).—We should advise you to exhibit the bird with good comb and ear-lobes, if, as you say, the difference in colour of legs is only a shade. A bad comb, or a bad ear-lobe is a very serious fault; a slight difference in the tint of the legs is not so important as either.

PULLET UNABLE TO WALK (9 X.).—Either your pullet has sustained an injury in the back, or she is suffering from severe constipation; or she is cramped from being kept in a house with brick, stone, or wooden flooring. If the first, her recovery is doubtful. If the second, repeated doses of castor oil will cure her. If the third, alter the flooring, or you will never have healthy birds. In the last two cases, after action in the first of them, bread and beer are essential, and if she will not eat she must be crammed. If the cause be injury keep her quite by herself, and feed lightly, avoiding stimulants.

CRÈVE CŒUR FOWLS, &c. (A Constant Reader).—They are not mentioned in the book you name.

BUFF COCHINS (J.).—As you require first-class birds, we cannot do better than recommend you to attend Mr. H. Tomlinson's annual sale of pure Buff Cochins, which will take place on Tuesday, February 10th. It is advertised in our columns to-day, and we understand the selection will include some rare specimens of the breed, birds that have taken cups and prizes at most of our leading shows, some of the hens weighing nearly 11 lbs. each, and the two-year-old cocks and cockerels being particularly fine.

BLACK BANTAMS' LEGS AT DARLINGTON.—Mr. Hutton says they were not adults, but only fifteen weeks old; and he, therefore, considers the legs may have become white in three months, not three weeks as we stated.

HENS PECKING A COCKEREL'S COMB (Constant Reader).—We should separate him from his assailants until his comb is quite healed.

OPENINGS WHICH EXCLUDE QUEENS AND DRONES.—"Will Mr. Bevan Fox kindly give the breadth of the slits he mentions at page 709 for excluding the queen and drones from ascending into the supers?"

[The breadth of the slits generally recommended for the exclusion of drones from supers is three-sixteenths of an inch. I am not quite sure that a queen would not be able to force her way through; but have no doubt that an aperture of this width would be effectual for the purpose intended.—S. BEVAN FOX.]

PIG-KEEPING (A Novice).—In "How to Farm Two Acres," which you can have free by post from our office for thirteen postage stamps, you will find full directions.

BUDGRIGAS (J. C.).—The Budgrigas are not Love Birds; they are the little Australian Grass Parquet. With reference to breeding them, we refer "E. C." to our Journal, New Series, No. 50. This is about the time of year they breed, and they should be kept in a room moderately warm.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 45.4° and 30.1° respectively. The greatest heat, 65°, occurred on the 10th, in 1831; and the lowest cold, 0°, on the 13th, in 1855. During the period 160 days were fine, and on 92 rain fell.

DO OUR SOILS DECREASE IN FERTILITY?

OUR opinion is, that cultivated soils not only do not decrease in fertility, but that they increase in productive-ness.

The subject is not now agitated for the first time,

but has been revived by a correspondent in the *Times*, who argues that the humus in soils is gradually exhausting, and that as it is exhausted those soils will become barren. Such, however, is an erroneous conclusion.

It was once believed, and is still believed by some men of science, that the soluble portion of humus—that is, of thoroughly decayed vegetables, which is called by them apotheme, is an actual food of plants, entering at once into their roots dissolved in the moisture of the soil. But modern researches have rendered it certain that apotheme is not thus absorbed by the roots of plants. Apotheme gives out carbonic acid which is absorbed by the roots, and they also absorb the salts and some other solids; but all in a dissolved state.

So far is humus from being essential for fertility, that some of the most fertile soils do not contain of it more than two or three per cent., and plants will thrive and be abundantly fruitful in soils where it is totally absent. Do not let us be mistaken as saying that humus is not a source of fertility, for it is so, undoubtedly; but other substances, such as animal substances, together with free exposure to the air by fallowing, will impart to a soil even a higher fertility than is imparted by humus.

Another section of scientific men—also entitled to respectful attention, for their leader is Liebig—believe that so far are plants from requiring humus in the soil, that they derive all their carbonaceous or combustible constituents from the air, and only their mineral or incombustible constituents from the soil. In consequence of this Liebig concludes that our lands are gradually becoming exhausted, and, eventually, will become barren, by being deprived of the mineral constituents required by plants. This dreaded mineral famine we believe to be as visionary as the dreaded humus famine.

A third section of authorities, having great antiquity and modern practice to sustain them, maintain that stirring the soil, and its long exposure to the air—in other words, well-worked and protracted fallowing—is the chief necessary to insure fertility. "What is cultivating a soil well? Ploughing it thoroughly. What is the second essential? To plough it. What is the third? To manure it," were the words of Cato, written more than two thousand years since; and Jethro Tull, and Mr. Smith, of Lois Weedon, have even gone beyond that

ancient, for they say manuring is needless. Such soils as those of Lois Weedon, a crop and a fallow alternately would not exhaust of their phosphoric acid and potash, probably, during the existence of more than one generation. But there are lighter soils which two or three years of such culture would exhaust of those minerals, and render them profitlessly unproductive.

We have no fear of our cultivated soils becoming barren either from an exhaustion of their humus or their mineral constituents; but neither do we look for succour to fallowing alone. We agree with Cato, for we think that good tillage is two-thirds of a soil's good cultivation; but we also think, as he did, that the other third is good manuring.

Above all, we know as a fact that our soils now produce far more per acre than they did five centuries ago, and that year after year farms now yield crops quite as abundant as they did in the time of the tenant's grandfather. There are—or, at least, we knew them thirty years since—fields in the Hundreds of Essex, which had borne crops of Beans and Wheat alternately for a time so long, that, as the lawyers say, "the memory of man runneth not to the contrary;" and we never met with a farmer or gardener of any soil in the United Kingdom, who, if he had labour and fertilisers at command, ever found the soil decline in productiveness. If we needed an illustration, we would quote the market gardens around London, where Potatoes and Cabbages are grown alternately, and have been so grown for a century.

We do not state without authority that our soils produce far more than they did five centuries since, for we have recorded in *Fleta*, who wrote about the year 1290, that the farmer could pay no rent, and must himself be a loser unless he could obtain *six* bushels of Wheat per acre.—(*Fleta*, ii., cap. 8.) So small a produce may be accounted for partly by the best soils being devoted to pasturage, flocks and herds being more required than corn to supply the culinary demands of a household whose chief food in those times was flesh meat.

As the vegetable portion of a household's regimen increased in proportion to that of the animal portion, so were the better soils converted from pasture to arable, which may in part account for our finding Harrison, writing in 1587, in the eighteenth chapter of his introduction to "*Holinshead's Chronicle*," stating, "Certainly the soil is even now in these our days grown to be much more fruitful than it hath been in times past." This he goes on to state was the case not only in England, but in Ireland, Scotland, and Wales; "so that each nation manureth her own with triple commodity to that it was beforetime." "Throughout the land (if you please to make an estimate thereof by the acre) in mean (average) and indifferent years, wherein each acre of Rye or Wheat well tilled and dressed, will yield commonly sixteen or twenty bushels, which proportion is notwithstanding oft abated towards the north, as it is oftentimes surmounted in the south."

Supposing these quantities to be correct, though there

is reason to believe them too large, yet there is evidence that the fertility of the soil has gone on increasing since then, for the lowest average produce of Wheat per acre is now stated to be twenty-eight bushels.

Our opinion that our cultivated soils increase rather than diminish in fertility, has not been lightly formed, but is founded not only upon the evidence of the oldest cultivators, but upon facts which seem to us conclusive.

It is quite certain that whatever is taken away from the staple of a soil by a crop grown upon it can be restored to that soil by manures, and by the natural depositions from the atmosphere; and we believe that there is no more well-ascertained illustration of the balancing which pervades all nature than that THE SEWAGE OF EVERY HOUSEHOLD IS MANURE SUFFICIENT FOR THE PRODUCTION OF ALL ITS VEGETABLE FOOD—a fact that cannot be too generally and continually urged, and in support of it we have this testimony of Dr. Lyon Playfair:—"Human excrements contain (with the exception of one ingredient—silicate of potash) all the ingredients essential to fertility. Estimating the amount of the effete matter of one man at an amount so low as 547 lbs. yearly ($1\frac{1}{2}$ lbs. urine, $\frac{1}{2}$ lb. fæces daily), so rich is this manure in phosphates, that the collected excrements of two men would suffice to manure an acre of Wheat or of Peas; or that of one whole acre of Turnips, supposing the green herbage were returned to the soil. In fact, when we recollect that a pound of urine contains all the ingredients necessary for the production of a pound of Wheat, it is incredible folly to allow all the valuable refuse of our large towns to run to waste, when at the same time we are sending fleets to Ichaboe and Peru for what we are wasting at home."

Dr. Playfair might have added with equal truth, that the excrementitious matters we are thus fetching from other regions of the world are far more expensive, yet not more powerful, as manure, than the excrementitious matters of our own sewers. On this point we will only quote the statement of one of our best practical farmers, the late Mr. Smith, of Deanston, who thus details his experiments made purposely on a meadow in Lancashire, by applying to separate acres at the rate of 15 tons of farmyard manure per acre, 3 cwt. of guano, and 8 tons of sewer water.

	£	s.	d.
Cost of manuring one acre with sewer water.....	0	12	9
Ditto with guano ($2\frac{1}{2}$ cwt.) at 8s.....	1	0	0
Ditto with farmyard manure, 15 tons, at 4s.....	3	0	0
Ditto with sewer water.....	0	16	6
Ditto with guano (5 cwt.) at 8s.....	2	0	0
Ditto with farmyard manure (30 tons), at 4s.....	6	0	0

The guano and farmyard manure "in their effects were found to be inferior to the sewage water."

The same law, we believe, prevails with regard to all herbivorous animals, and that their excrets, aided by the atmosphere's nitrogenous depositions and its carbonic acid, fully restore to a soil all that they withdraw from it in their food.

When we add to this, that annually fish, seaweed, guano, oil cake, ashes, bones, coprolites, and other animal sources of phosphates, as well as bread stuffs, sugar, tea, and other foods, are continually being imported, or won from the sea, we discern sources of increased fertility, but none of impoverishment.

It is true that in towns the human excrets are for the most part wasted; but this proves no more than that if they were all husbanded as they are in China, our soils might be made still more fertile, and, as in China, capable of supporting a population still more numerous.—J.

NEW PLANTS FOR THE COMING SEASON.

THE first plants on my own list for trial next summer are three kinds of Calceolarias; the Calceolaria Aurea floribunda to be used as a sample plant to compare the others with under the same treatment, soil, and situation.

Before going farther, let me protest against a common error in judging of new plants for bedding purposes. A very sensible man, out of every degree of sensibleness from a florist to "the man" in the garden, obtains a new plant or plants, and it reaches him in the best condition and he does his best by it; but the season is against him or is too much in his favour, and in either case he can only put out his new comer or comers in some place by themselves and watch them. No doubt the worst place about the garden is not where people put out their trial plants. But no doubt, also, unless there are as many

plants of some old kind for which the new are rivals put out on the same spot of ground as the new ones, and under precisely similar conditions as to the size, age, and health of the plants, the trial and the judgment on the issue are both wrong and of very little value, and yet the person who conducted the trial may be one of the most conscientious of men; he only went the wrong way to work without knowing it, and he is not aware that his decision, in consequence, is worse than useless, for it may be most mischievous. Then, knowing all that, the first thing I do when I have to trust to another's choice of a new plant, is to ascertain what means were within his reach by which to form his judgment. Of his judgment I may not have the least doubt; but I am very doubtful whether or not some of my friends' judgments ever had a fair chance of being in accordance with the nature of the subjects under experiment.

If I took six plants of Tom Thumb when it first came out, and gave them the best position on a trial border, and compared the rise and progress of the new seedling with the advance of Lady Alice Byng, or of the Crystal Palace Scarlet, or of the three kinds of Frogmore Improved, which I had then out in the beds, and which were the only sorts then against which Tom Thumb could compete on fair terms, my judgment might do for myself, but it could not be a fair judgment of an experiment to come before the public. The least I ought to have done would have been to have given an equal chance to as many of Tom's rivals as to himself on the same border, and all the conditions to be exactly alike as to age, strength, and health of the plants at the first start: therefore, whatever the season might be, all the plants had their share of it under the same circumstances, and the judgment could not be far wrong in so far as this—that if the season were very bad, one or two of the kinds might stand it better than the rest; or if it were a most favourable season, the rest, or one of them, might be the superior for that season and seasons like it.

So you see there is more than meets the eye, at first sight, in a faithful experiment to test the value of the simplest plant that one chooses to deal with if in earnest about it.

Well, then, I have so many plants of Aurea floribunda Calceolaria, and last summer our Floral Committee gave their highest award for such plants—their Certificate of Merit for Calceolaria Cloth of Gold to Messrs. Downie, Laird, & Laing, as you would have seen in the last Number of this Journal; and the year before last our Floral Committee gave the same award for Calceolaria canariensis to Mr. Smith, the great Fuchsia florist of Hornsey Road Nursery; and these two Calceolarias I shall engage to match against Aurea floribunda for a thousand guineas, or a thousand to one that the three will have the same and the best treatment that I can give them. But, perhaps, you are not aware that I am equally interested in the three kinds. I was the first person to prove to the public the use and value of Aurea floribunda in the Experimental Garden. I had it direct from the raiser through Mr. Turner, of Slough, for that purpose, and I had to thank Mr. Turner for giving me a lift in the matter. The plants were hurt by a railway run, or crash, or something, and Mr. Turner kept and nursed my Aureas for me until they were fit for a prince to plant. I have been always proud of Aurea ever since, but it shall be on the same level now.

Last summer was so bad for Calceolarias, that many made up their minds to discard this, or that, or these old Calceolarias, and take in some of the new ones. I recollect looking over from the galleries of the Crystal Palace with Mr. Gordon, when he told me he would plant no more of his principal sort, the best of the Rugosa breed. The only one which held the flowers on there against the drenching rains was Gaines' Yellow; and now that I think of it, I must have so many of Gaines' on the opposite side to Aurea floribunda, with the canariensis, and the Cloth of Gold in the centre.

The reason why I am so much interested about these two is, of course, from the fact of their having their character stamped by the Floral Committee. But speaking of the Crystal Palace broke the strain of my thoughts on the matter, for there is where we all had the opportunity of seeing and of believing in the most beautiful and most distinct new Lobelias of the dwarf blue race that ever yet appeared in one season. One is called after Sir Joseph Paxton by permission, the other after Mr. Gordon at my request; and I have another one from down the country, of which I thought very highly, from a chance blooming, but not so much as to determine its degree in the scale of merit. So I shall have three capital dwarf Lobelias to decide

upon; and I am quite certain myself each one of the three is at least as good as the best variety of *speciosa*; but, what is more fortunate, neither of the three will be a rival to *speciosa*. You might make a bed of any of the three, and put *speciosa* round it for a contrast, just as one could make a bed of one of the *Cerastiums*, and put the other round it as an edging—which plan, I believe, will be adopted next summer at Hampton Court.

We may as well keep to the edging plants and finish them first. The grand accident new edging plant of last summer will most assuredly be a great favourite in a short time, I mean *Arctotis reptans*. This I have proved myself, and I sent it to some of the dons on my way to one of the exhibitions. I took up a full yard of edging of it on my shoulder, to try and win a prize with it; but instead of that, I got well nigh the end of my journey before I was half way up the colonnades at South Kensington. Talk about garotting and night work, I had to share my prize edging plant amongst so many smart men, that I had no more left than what I had intended for Mr. Eyles. I also sent it to the Botanic Garden, Regent's Park, to the Crystal Palace, and they have it at Kew, so it will be out about London in abundance; and all I need now say about it is, that seedling plants of it do not do well the first year, but the bulk of the people must have it from seeds, if it is in the market, in order to obtain a stock of it. Of all my store plants, in the cold pit, this is now the most promising to keep that way from autumn suckers, or rooted shoots, for every inch of it roots as freely as Strawberry runners in the edging. I have only one store-pot of it, and if it bloom with me that way, I shall take the pot to the Floral Committee, to let them see what a nice flower it is, besides being the poor man's best pot edging plant, one of the easiest to manage, and good enough for a prince.

The next lot with which I mean to be smart this summer is a lot of the best Fancy Pansies, beginning with the Duke of Cambridge's fancy flower, the new belted Pansy called *Aurea marginata*, for which the Floral Committee had given a prize to the Messrs. Downie, Laird, & Laing, and which is a novelty even amongst the novelties of the Fancy race—a race which is much harder and more easy to manage than the florists' Pansies, although I missed the right way of growing a collection of them two years back, and blamed the cocoa-nut refuse for it.

Mr. Dean, of the Bradford Nursery, the great authority for this class of plants, has told me the right way to grow them, and I saw in a moment where my way was wrong altogether. I thought of staking them because they grew away so fast in this stuff; but no, he told me the right way is to train them down, and to put a little fresh compost from the potting-bench refuse, twice during the summer, among the shoots into which they would root, and continue on blooming to the end of the season. That is just how I shall do them this season, for I mean to go into them in earnest now that I have so many of the best new ones—such as *Harlequin*, *Impératrice Eugénie*, *Princess Louise*, *Mulatto*, *Leotard*, *Pacha*, *Prince Napoleon*, *Adelina Patti*, and such good sorts; and as soon as the double "Good-Gracious" comes out, I must have it of course. Then with my stock of the *Magpie Pansy*, my *Yellow Perpetual*, which I had from Mr. Sims, Foot's Cray, Kent, nine years back, and which never yet failed from April to October, and the blue *Trentham-bedder Pansy*, one of the best and most sure of them all, I ought to be pretty well off in this class; and of course, also, I shall push hard to find out rivals, and never cease until there be a bed or two of the race in every flower garden where there is room for another bed.

Then, I have just received by the last mail from New York a splendid new strain of striped and fancy-marked *Petunias*, which will Merrimac Mrs. Ferguson, and all Mr. Williams' and Mr. Holland's new strains, if the seeds come true to the plate of figures of them which has been sent me with the seeds by Mr. Buchanan, who had the celebrated sale of Cacti at the Baker Street Bazaar in 1840, and whose acquaintance I then made as a bird of a feather. He reads this Journal regularly in New York, and likes it more than any of our London Pride for tales about "breeding-in-and-in and crosswise with long stamens and with short, to say nothing of our backgroounds, middle masses, or front rows in the ribbon system," and all the rest of it. The *Petunia* seed was accompanied with the request that "if there is anything there I should like to have I had only to mention and I should have it." Very good, and I take Mr. Buchanan at his word. Send over by the next steamer the two Presidents to me, and if I can get them to shake hands and give up the darkies, I shall

go over and settle about the stars and stripes on the ribbon system of harmonising for effect, and thank him for the chance as much as for sending me this new strain of striped *Petunias*.

D. BEATON.

SUCCESSION OF PEAS—SMALL GREENHOUSE—HYACINTHS.

I HAVE to thank many kind correspondents for their information on the above subjects, and hope they will take this as a reply to the notes they have been good enough to write. With regard to Peas, I rejoice to find that I am not singular in my dislike to the large sweet Marrows, which, by-the-by, I think are quite as good raw as boiled, and are fit food for such strong stomachs as can digest them. Various suggestions have been made as to keeping-up a succession, but the one which commends itself most to my notions is to make Sangster's No. 1, *alias* Daniel O'Rourke, *alias*, &c. (for it has many names), the first crop; to sow for the second Bishop's Dwarf Longpod, and, at the same time, the old Blue Scimitar, and that then the Blue Peas will come in about a fortnight after the Bishop's; and then to sow, for a succession during the summer, the Blue Pea. My object was not to know when to sow Victorias, Ne Plus Ultras, &c., but to get rid of them altogether, and to substitute some Peas which, neither so large nor so sugary, might be gathered throughout the season. I do not think that I should care to have Sangster's No. 1 all through the season. It will do very well at the beginning, and also for a late sowing to come in at the very last; while my recollections of the Blue Peas induce me to think that I should not require anything higher-flavoured than they are. High cultivation, oftentimes for the sake of size, symmetry, or some fancied quality, destroys flavour. I would infinitely prefer a leg of Cheviot mutton to one off the finest and most symmetrical Leicester that ever received a first prize. So would I select a sirloin from a grass-fed ox, to one off the fattest and ripest (what a term!) that Baker Street ever saw; and so I am Goth enough to prefer the small, delicate-flavoured Peas to the large and rich ones. It may be most desperately bad taste—might put me into the "Index Expurgatorius" of the "Almanac des Gourmands;" but it is my misfortune if it be so, and I can only rejoice that some others think with me.

As regards the greenhouse and its ventilation, I should have, perhaps, said that as my little garden is merely a piece taken off a field, without any ornamentation, shrubs, trees, or anything of the kind, my object is to have the very plainest and cheapest one possible; anything else would be completely thrown away. This must be my answer to Mr. Cranston, who very kindly sent me both a sketch and estimate of one. Nothing can be more beautiful than his designs, giving, as they do, an ornamental appearance to what is generally speaking a very unornamental object, and, so far as my limited knowledge of such subjects goes, the ventilation seems excellently managed; but then, on the score of expense and unsuitability to my location, I must, however reluctantly, abandon all hope of erecting such a house.

To a brother clergyman in Dorsetshire, I am indebted for a communication which is more in my way. He, too, like myself is exposed to the rude assaults of blustering Boreas; and has, therefore, been led to contrive something which shall give him an opportunity of ventilating without being blown away. His roof is, I take it, although he does not mention it, a fixture, such as I intend mine to be—that is, made simply of bars without sashes, and glazed with large panes. This will prevent much drip; for it is the force of the S.W. wind, driving the rain literally into the house, that I have to avoid. Last night it rained a downpour, but then the wind was from the N.W., and my house hardly leaked at all; while, with half the quantity of rain from the S.W., it would be dripping all over. His ventilation is managed at one end and the front, although "DORSETSHIRE" prefers it at both ends when it can be had. His front sashes at the opposite end to the door open like a door on hinges—in fact, like a cottage window, and are kept open at any angle by ordinary screw cottage fastenings. The ventilation at the end is managed by having a sash or sashes to open by means of a simple contrivance with two pulleys, and this can be done by any one standing on the floor of the house. It is, I think, clear that his house is larger than what I intend to put up, but this does not alter the principle; and it seems to me to combine simplicity and economy. As regards

heating, I do not suppose any plan is preferable for so small a house to that of the old brick flue; and by altering the furnace, and bringing it a little farther on, it will adapt itself to the increased size of the house. I have thought at times of hot water; but there seems to me to be so much power wasted when even the smallest boiler is applied to a house of this size, that I have given up the notion, especially as my only object is to keep the frost out, and I have no ambitious designs of forcing or extensively propagating.

I may take the opportunity while the pen is in my hand of answering "R. A. H.'s" questions as to the Hyacinths he intends exhibiting. I think he did wrong when potting not to have put a larger proportion of manure. One-fourth is not enough. I generally put one-half, and have known some growers make it even three-fourths. However, he must now make up for it by liberal supplies of liquid manure. I should prefer this, I think, to guano water, considering the circumstances under which they were potted. I am myself using guano. They should when taken out of the ashes be gradually inured to light, and as the Exhibition at which he intends to exhibit them is not to be held until April, they will not require any heat but rather retarding, especially if this extraordinarily mild season continue. One great object he should bear in mind, is to have good foliage as well as good bloom, and that, therefore, he should endeavour to avoid drawing the plants, and thus prevent the leaves from hanging down and falling over the sides of the pots, than which nothing can be more ugly.—D., Deal.

WHAT DESTROYS CROCUSES?

As our Crocuses have come above ground this year, they have been attacked by some animal, but we cannot ascertain what. The stems are cleared of earth all round, and then cut about half an inch from the root, the roots not eaten, and nearly the whole cut stem left on the ground; the mischief is done at night. We attributed it at first to mice, then rats; but no sign of these could be discovered, and none were caught in the traps set. These generally eat the root as well. The mischief continues as the flowers advance, and of late the plants are attacked as if by a pig, the holes are so large about them, still only the stems are cut as before described; all our Crocus-borders are destroyed. Can you suggest the cause or a remedy?—W. W. BENNETT.

[The sparrow does the conjuring, and as it would seem through sheer mischief, but in reality only to sip the nectar at the bottom of the tube of the flower, while the flower is yet in bud, the instinct of the bird being thus exemplified.]

CULTURE OF BEGONIAS.

VARIETY is the most distinguishing feature in this class of plants—distinct variety in the colours of the flowers and a pleasing variety in the markings of the foliage, which are all displayed with a graceful habit of growth during the dull winter and spring months, when flowers, like many other things when rare, are most valued. The majority of Begonias being natives of South America and the West Indies require stove temperature. Some new and good sorts have of late years been produced by cross-breeding, and it is probable that by that means a more hardy race will be created. Mr. Frost, gardener to E. L. Betts, Esq., of Preston Hall, near Maidstone, raised a cross called *Begonia prestoniensis* by impregnating *B. cinnabarina* with *B. nitida*; the flowers are abundant, of a brilliant scarlet, fragrant as a rose; and the plant has a shrubby habit, and succeeds well in the greenhouse.

If collectors of plants were more particular in giving us an account of the localities in which the species were generally found we should not be compelled to grope our way in the dark so often as we are. To say that many species are natives of South America is giving us a very extensive range of country to investigate. The variety of climate from the summit of the lofty Andes covered with snow to the valleys luxuriating in a tropical temperature, with the collateral influences produced by proximity to the sea or to rivers, to lakes or to mountains, should suggest to every collector the necessity of giving such particulars of situation, soil, &c., as would lead us to the treatment most suitable for each. It was, I suppose, by some mere chance that we have discovered, after many years of haphazard treatment, that the *Begonia nitida*, introduced from Jamaica, will do well

in a greenhouse temperature. The *B. Evansiana*, *syn. discolor*, introduced from China, is a species very frequently found in great perfection in the cottagers' windows. By cross-impregnation with such parents of a comparatively handy constitution we shall ultimately attain a class of Begonias endowed with all the properties of the best sorts, and amenable to greenhouse treatment.

The Begonias may be divided into three classes—the fibrous-rooted, the herbaceous, whose stems die down annually, and the bulbous-rooted sorts. The most useful particular with which we have been favoured by collectors is to know that they are generally found to inhabit moist, shady, and secluded situations in their native countries, where they are partially sheltered from the direct rays of the sun and from cutting winds. In such situations it is reasonable to suppose that leaf mould is the soil in which they flourish. With us they delight in a moist atmosphere with a slight shade on hot sunny days, good drainage, an abundance of water in their growing season, and half leaf mould and loam. They grow luxuriantly in a soil composed entirely of decayed vegetable matter, but in that they are very liable to rot-off at the base of the stem. Being of a most succulent nature they would luxuriate in the atmosphere of a vapour-bath, as in their native countries, without the necessity of requiring much root-action. Stopping or pruning they will not bear, and the only occasion on which the knife can be used with safety is to cut away the old stems from all that throw up strong shoots from the roots every year. To counteract the tendency to rot it is advisable to slightly elevate the stem in the centre of the pot. The sorts that form tubers, such as *B. Evansiana*, *diversifolia*, and *octopetala*, should be dried-off cautiously as the season of growth declines, and stored away in any cool dry place for three or four months, when they may be started and repotted into fresh soil. About the beginning of October, when the leaves of some begin to fade and others assume a languid appearance—indications of the natural rest that they require—water should be gradually withheld, and entirely discontinued by the first week of November.

Although many species would remain green and healthy during the winter it is not in accordance with the natural habits of the plants to keep them in a continuous state of growth. Indeed, all plants want a season of rest, more especially the natives of tropical countries where sun and light are more intense. In our dull and generally unless winter months the growth that is made by the application of artificial heat is only the elongation of the parts without maturity or vigour. A continuous growth is an abortion. A mature and properly elaborated vigour of growth is essential to the production of flowers, and a premature and excessive development of the branches and foliage at such a season is injurious and often destructive to the desired effect—the production of flowers.

The majority of the sorts are easily propagated by cuttings; but by many growers seedlings are preferred as not being so liable to rot-off at the base of the stem. The seeds when ripe are scattered upon the surface of light sandy soil, covered with a bell-glass, and shaded.

The following is a list of good sorts:—

- Begonia xanthina*.—Conspicuous for its yellow flowers.
- B. prestoniensis*.—Brilliant scarlet.
- B. cinnabarina*.—Citrone-coloured flowers.
- B. fuchsoides*.—Scarlet.
- B. rubrovenia*.—White, streaked with red.
- B. Thwaitesii*.—Foliage of green, deep red, purple, and violet colours.
- B. Fischeri*.—Blush-coloured flowers; foliage bright crimson beneath.
- B. rupestris*.—Pink flowers; leaves marked on the surface with white silvery-looking spots.
- B. Martiana*.—Pink flowers generally in pairs, but in great profusion.
- B. zebrina*.—Pink flowers; leaves bright green, smooth and shining, marked with dark green shades on the under side.
- B. argyrostigma*.—Flowers flesh colour; leaves dark green, singularly blotched on the surface with silvery spots.
- B. odorata*.—Pure white flowers.
- B. nitida*.—Pink flowers; straggling habit of growth; suitable for trellis.
- B. sanguinea*.—Dark purple leaves; white flowers.
- B. cruenta*.—Bright scarlet flowers; stems of a dull crimson colour.

- B. ulmifolia*.—Blush-coloured flowers.
B. castaneifolia.—Blush-coloured flowers; neat habit of growth.
B. semperflorens.—White flowers.
B. cuculata.—White flowers; stems slightly tinged with purple at the joints.
B. papillosa.—Pink flowers.
B. digitata.—White.
B. rubra.—A beautiful red not only in the petals but also in the capsules.
B. platanifolia.—Pink and white.
B. heracleifolia.—Pink blossoms, low habit, and dark green ivy-like leaves.
B. Barkerii.—Immense leaves, and a large head of odoriferous flowers. Increased by seed.
B. hernandiæfolia.—Rosy-red flowers.

W. KEANE.

HEATING HORTICULTURAL BUILDINGS.

MANIFOLD as are the modes by which glass structures and other places devoted to horticulture are heated, the subject is certainly far from being well understood. True it is that those who have had extensive practice in heating may be able to give opinions of considerable weight on the matter; but there are many who may not have obtained such experience, and, consequently, may be led into error—not, perhaps, always in neglecting to provide sufficiently powerful heating apparatus, but by running into needless expense in providing it in a manner not required. This is also a subject in which the most experienced sometimes make mistakes, therefore I offer no apology for making some observations upon it; not that I have anything to advance in contradiction to the able communications Mr. Fish has from time to time put forth, but some additional facts bearing on the case which, if not new to the practical men who keep pace with the times, will at least be interesting to the general reader.

I believe it will be admitted by all, that the best-constructed heating apparatus yet erected falls far short of supplying the heat that ought to be furnished by the fuel consumed; in fact, so extensive is the waste, that the statements of the learned men who have treated on the subject seem almost startling, but it is questionable whether anything even like the results they assume to be possible will ever be secured in practice. Nevertheless, there is every reason to believe that very considerable improvement may yet be made; and although the combustion of a pound of coal may never effect the wonderful changes that men of science assert it ought to do, it may yet be so economically used as to impart a greater portion of heat to the object wanting it than it now does; and if a mode of doing this without entailing additional labour or cost can be found, the discoverer will deserve well of his fellow men.

The present notes, however, will be devoted to the application of heat to such purposes of horticulture as tend to impart heat to the atmosphere of a structure adapted to the cultivation of plants. In thus limiting its operations, we must also fetter it in another way as well. The heat supplied must not contain any gases hurtful to vegetation, but must simply be a good and agreeable warmth, free from any impurity; neither must it be too dry nor yet too moist; in fact, it ought to be completely under control in these last two respects, and at the same time the simplicity of the apparatus must be such that any rustic may be safely trusted with its management. It must, besides, require no particular attention calling the operator very often to it, for there may be times at which the man or boy who has the charge of such works may want to be somewhere else; and if an apparatus for heating requires attention every hour or two, there is every probability of this duty being often neglected.

In the cultivation of exotic plants, it is often necessary to increase the temperature of the atmosphere they are placed in to something like that of the country they came from; or, at least, we are obliged to prevent that atmosphere from being cooled down so low as it would be in our climate. To prevent this artificial heat has to be applied; and whether this heat be in the shape of fermenting material or fire heat, the object must be accomplished. Other modes of heating have been suggested, as making use of the heat from the sun's rays; but we have not yet found the way of concentrating the spare heat that might be so obtained, and giving it off at night, although this is far from

being so improbable as some may suppose. Neither has a much more difficult problem—that of taking advantage of animal heat, which was suggested by some one, been hitherto solved. If I remember right he proposed to have a forcing-house, or something of that kind, immediately in front of a row of cattle tied-up and feeding. The warmth from their bodies and their breath together, he thought might supply the heat required. How such a system would suit the owners of stall-fed oxen, I must leave them to say; and how the animals themselves would enjoy the tantalising prospect of green herbage, rich, tempting, and pretty, but out of their reach I cannot aver. It is almost superfluous to add that the plan has never yet worked itself into practice, neither is it likely that it will be adopted by any but by those anxiously bent on novelty; for it is probable the improved modes of using fire heat will drive all others out of the field. I believe there have been other modes of applying heat suggested, but it is needless recording them. Let us, therefore, see in what way the two most available modes of heating, which are fermenting materials and fire heat, can be used; the latter, of course, including hot water, &c.

To the fermenting materials supplying heat it is hardly necessary to advert, as local circumstances generally point out which must be used; and useful as such an assistant is to the forcing-gardener, there are many plants which cannot be carried through the dark days with them alone; for the steady warmth given off by a bed of tan, dung, leaves, or similar substances is not capable of being suddenly increased to meet the fluctuations of temperature not unusual at Christmas or afterwards. A sudden depression of, perhaps, 30° in the external atmosphere, tells also to a certain extent inside a glass structure; but fermenting material alone is incapable of any increased effort likely to compete with this diminished temperature. In the generality of cases, therefore, requiring a steady high temperature in winter, it is necessary to call in the assistance of fire heat as well; and the latter being completely under command, and being used more or less as occasion requires, the best results follow, the union of the two being certainly better than either alone. Although there are plenty of cases in which fire heat does the whole, and that very well too, still a body of fermenting material has advantages which no artificial combination in which fire, water, and iron are alone employed can afford.

FIRE HEAT.—Having adverted to the loss in all cases entailed on the user of fire heat, I may here add that no one loses so much as the forcing-gardener. With him combustion goes on in one place, and the air required to be heated is separated from the fire by large masses of brickwork. Possibly the fire is made to do duty on some boiler, which sends its warmed fluid in circulating currents through some long and intricate series of piping, which in turn has also to be warmed, in order to afford the tardy warmth given off to the atmosphere either above or surrounding the pipes. Of course all their auxiliaries or appendages have to be warmed by the fire before any heat is given off, and, by the time the fire heat reaches the farthest object it has to be applied to, it is divested of much of its warmth. This is the evil, and how to remedy it has puzzled the learned in such matters for many years; and although much improvement has been and continues to be made, by the better construction of fireplaces, the advance in heating horticultural buildings falls far short of what has been done to improve the construction of sitting-room fire stoves, kitchen ranges, &c.; while gas, Arnott, and other stoves to heat shops, halls, and public buildings have likewise undergone many improvements.

Although the subject is, perhaps, not quite in order here, I may say that one of the best heated churches I was ever in is warmed on what is called Sylvester's plan of heated air. The apparatus was made, I believe, at Trowbridge—at least it bears that name—and is unquestionably a great improvement on all the modes of heating such edifices I have ever seen in use. Of its economy I can say little; but should suppose, by its warming such a large volume of air, that the fire heat must be carefully employed. Of its applicability to horticultural buildings I can also say little; perhaps, however, this mention may draw forth more precise information on these points.

Heated air has often been held in dread by the gardener, as likely to contain some noxious gas fatal to his plants; but, in the mode of heating I allude to, it has none of the Arnott's stove stifling smell so often complained of, and it is possible that for forcing purposes it could be still further improved or purified. Heated air is unquestionably the most economical way that fire heat can act on an atmosphere which it is neces-

sary to warm; and as soon as such an application of fire heat can be effected without injury to the plants, a great advance will have been made. A talented, though somewhat versatile, writer on horticultural matters suggested, many years ago, the propriety of trying an open fire in a forcing-house, and reasoned hard on the probability of its answering; but I have never heard of its having been put in practice, neither is it likely it could be made to act for all the purposes for which he advocated its adoption. It would, however, be interesting to know if any one has succeeded in keeping an ordinary greenhouse sufficiently warm to exclude frost by means of an open fireplace within it.

J. ROBSON.

(To be continued.)

SOMETHING MORE ABOUT POTATOES.

I DWELT long over that extraordinary part of the display designated "Garden Roots and Vegetables" at the great International Show of the Royal Horticultural Society in October last, till, from the number of questions put to me, I began to consider myself as a standing dish; though I fear, if a balance could be made, I gained much more information than I was enabled to give—such confidences struck up on the instant, that many mere lookers-on may have imagined in their thoughts, "Hark at those old friends!"

I now send you the result of what I thought to be the cream of the cream of the Potatoes there exhibited—sorts practically unknown to me, though most of the kinds were there that I have already tried and spoken of in these pages, and which on the present occasion it will be superfluous to again touch upon, except in a few instances. But for the varieties that I now bring into notice, perhaps those friends who may be acquainted with their qualities will let us know and correct my judgment in cases where I may be wrong in having fallen over head and ears in love at first sight.

In one instance at least, the *Barbadoes Potato* has been inquired about by "A CONSTANT READER," Dec. 23, page 759: therefore my task will not be wholly in vain, and he will be glad to be informed that his old friend "is still in existence."

Alstone Kidney.—A good-looking, white, fluke-shaped Potato.

Barbadoes, exhibited by Mr. E. Bennett, gardener to G. S. Foljambe, Esq., Worksoep.—A roundish-oblong Potato. Very fine, as large as one's foot.

Bath, by Mr. Bullock.—A very promising-looking "early" Potato.

Jackson's Seedling, from Mr. Robinson, Shaw House, Melbourne, I thought to be a fine pear-shaped Kidney variety. It was also praised to me by a practical-looking man as being an "incomparable early Potato." I recognised it as being what I called the "Lambton" in my "Comparative Merits."

King's New Seedling.—From the Fluke, a second early round. This Potato attracted much attention.

Kirkton Early.—This Potato I mention from hearsay, as an Hon. Col. M.P. recommended it to me strongly in conversation as being an excellent round variety. I cannot take the liberty to mention his name, but he told me he reads this Journal; so I merely take an opportunity to say how sorry I was when a gentleman enticed him away from our Potato palaver, for, as a matter of course, we should have naturally veered towards that part of the Show, and once there, doubtless further valuable information would have been gained from him for these pages.

Lemon Kidney, I observed, was showing its precociousness already by "breaking" on Messrs. Sutton's magnificent stand.

Murton's Seedling, from Rev. T. Stevens, St. Andrew's College, Reading.—A Potato in appearance very like the Fluke, but having a rougher skin. In Mr. Stevens' fine collection I also noticed Daintree's Seedling showing its precocity by "breaking;" and I can very plainly assure you that it requires looking sharp after in this respect when kept in store for eating.

Wellington.—A magenta-stained-crowned roundish-flat-shaped Potato, very taking as to looks, and a monopoliser as to names. I fancy I recognised it under seven or eight aliases—viz., Magenta, Model, Malakoff, Early Beauty, Early Stockton, Early Sydenham, Ward's Seedling, and Painted Lady.

Oxford Red, from Mr. T. Westbrook, Abingdon.—A monstrous pinkish-skinned Potato, all over eyes, in fashion of the Negro, a sort I mentioned in a previous article—both of them calculated to astonish the natives.

Peach-blossom, from Andrew Arcedeckne, Esq., Hall Farm,

Wickham Market, Suffolk.—A sort "grown from seed imported from New York," and it may just possibly crumple-up some of our old sorts.

Queen, by the Rev. Thos. Stevens.—Another seedling from the Fluke, and a promising-looking Potato.

Royal Sovereign, from Mrs. Sweetlove, Mote Road, Maidstone.—A moderate-sized, beautiful-looking, smooth-eyed, white Potato—a perfect model in appearance in my mind as to what a round Potato should be, and as charming as the lady's name who exhibits it.

"*Seedling*," from the Kirke's Ashleaf.—Exhibited by T. Westbrook, Abingdon, "Warranted to be the Earliest Kidney in cultivation."

White-blossomed (Ashleaf?) *Kidney*, from William A. Page, Godalming.—"Grown entirely in rotten tan;" and

Webb's Imperial Kidney.—These two varieties I mention, the latter especially, as being congenial to those who would like to see their Potatoes, as some people do their butter, fashioned a yard long.

I thought many of the kinds of Potatoes most worthy of note in the Foreign department might be recognised as English kinds under foreign names. All of them, moreover, were small in comparison to their relatives over the way.

In the Swedish class I met with "Roda Moss," with which I had a practical acquaintance this season, as the Salmon Kidney. It was also in the English class, where its proprietor caught me by the button and fairly enticed me a hundred yards to view it. Poor man! how enthusiastic he was about it, and he had written its name "sammon kidney!" I confess to have mentioned it rather slightly in my "Comparative Merits," and I really owe it an apology, as well as the Fluke, if I have wronged them by so doing. *Potatis Maccaroni*, as well as some other sorts, were woefully diseased in the Swedish collection; but, strange to say, the Flukes were the only specimens that I observed to be diseased in the English class, and the only sample with that unenviable feature in my own stores is the Fluke.

I will notice two other sorts of Potatoes in the extensive display of "The Hamburg and Altona Gardeners' Society," founded in 1861.

Kartoffeln Pomatyerans Ringam, rather an oblong-shaped Potato; and *Neuwe Kanarische*, a round Potato, in shape and looks exactly like a very good sort I introduced into this neighbourhood some eight years ago, called Martin's Seedling. The Judges set it down that the two Potatoes exhibited were the same variety. I differed from them as a mere looker-on, but I should like to know in the future who was right? I had not an opportunity of learning who purchased those two sorts, but the whole collection was to be sold for the relief of the Lancashire distress. All honour be to their purchasers, and to the gardeners of Hamburg and Altona!

When judgment is wanted, who can we appeal to more impartial than our Editors? Most of us, I daresay, feel an inkling of prejudice in favour of our own productions; and for that very reason, and on account of the importance of the subject as regards the cultivation of the Potato, I would feel obliged by an opinion from head-quarters.

I was quite struck the other day at the difference in both the looks and flavour of the same variety of Potato when grown on the flat and on the ridge—Nos. 1 and 2, for instance, of which I send you samples from both plans; and Nos. 3 and 4, ditto. Please to test them, and allow me to advise you to have both of the same sort cooked at the same time for observation at once. Perhaps you may also think that the ridge-system has a knack of producing them calculated to fill a measure, and weigh down the scales as well as to produce, quality, and flavour.

I should very much like an opinion also, as to what you think of the flavour of the Knight's Monarch Pear, as I have something to say about Pears some day. I have had a long struggle with them to produce flavour; and although those I send I do not consider up to the mark, still, for some years, both the Knight's Monarch and other sorts were very little better in flavour than turnips, and the rector gave me no hopes of encouragement that I ever should produce them here presentable for dessert. I know to within an inch where every root of every tree lies, and I have presented them with three different descriptions of soil in fourteen years, and the rector confessed that we had some very good Hacon's Incomparable, and some first-rate Marie Louise last season; and if I can but produce them with flavour this year, I shall consider my experiments as feats accomplished.

The Blenheim Pippin is a sample from an old tree which would scarcely produce Apples larger than crabs. I added fresh life to its constitution by taking out a trench a yard wide and deep around the circumference of its branches, refilling with rotted turf compost, and I thinned out its head. I scrape off the loose bark, and soot and lime wash its bole and larger branches every spring, and give a thorough good soaking with 600 gallons of house-sewage, just as the fruit begins to swell annually. That is the man—or rather the Apple—as Beau Brummel formerly said of starch.

The specimens of Cox's Orange are from the young pyramidal tree which I mentioned in these pages a short time ago. As regards condition both these Apples are a month after their season, but I wanted you to see the Blenheim Pippin, just to show to you what an old tree can be made to do, and to induce others who may have old Apple trees inclining to wear-out, to go and do likewise. How I should like to have the handling of some of the hoary-headed moss-grown trees in the orchards of Devonshire! What a wiggling I would give them! Oh, that our Devonshire aparian friends would dip their facile pens in a little gall and bitterness, and sting a great many of their countrymen to action upon the spot! So many broad acres, and so many comparatively young orchards that are there giving small returns for want of a little exertion! And then, if some of them were to retaliate on Mr. Woodbury—at least, if they are bachelors—I should rejoice, on account of that poetry, a translation of which he gave us at page 42, from the German.—UPWARDS AND ONWARDS.

[The Knight's Monarch Pears are not large, but of more than average flavour. The Blenheim Pippin as large and as good-flavoured as any we ever saw. The Cox's Orange small, but well flavoured. The Potatoes all bear testimony in favour of the ridge system of growing, not only by their superior size, but excellence of quality.—Eds. J. of H.]

TREATMENT OF APRICOT TREES IN BLOOM.

THERE is a common saying in this part of the country when a person feels he has to contend against sophistry in place of argument, "Now don't throw dust in my eyes." I cannot help feeling my friend Rivers has been dealing in dust. He is quite aware I have insisted on the necessity of a dry atmosphere and dry pollen to the proper fertilisation of the flowers of fruit trees, and I have even thought I was at unnecessary pains to secure this object. He will find if he refers to my article of December 30th, I only threw out a suggestion that the sprinkling of Apricots occasionally before and during blooming might be beneficial.

Now, I would ask, Supposing all the ventilators of your house to be open, and you sprinkled a tree all over the first thing in the morning, or say at breakfast time, how long would the tree remain damp with a dry wind passing through the house? Could it possibly prevent the pollen being dry by eleven or twelve o'clock? I know my success in Apricot culture has been as great as any one can boast of, but it has not been sufficient to satisfy me, and I am anxiously feeling my way to comparative certainty.

Can any one acquainted with the slopes of the Atlas Mountains or the hills of the Caucasus, say if the soil in those localities is dry as dust all winter, or the trees entirely unvisited by rain during the blooming season? If so, then clearly the suggested experiment will result in failure, but if confined to "two trees" it will not be a serious one.

Let me give my reasons for trying the experiment I suggested, for, remember, it is only an experiment at present.

Some years ago I noticed three large Apricot trees full of bloom in my farmyard. It rained with a strong west wind almost every day; and the trees, being trained to a western aspect, were, of course, exposed to the full force of the showers. When it was not raining the sun often shone brightly, and I remarked several times how strong and healthy the blossoms were. One day the weather turned much colder; the trees were covered with snow, and as there was a slight frost, I thought it all over with the Apricots; but they never set so thickly on those trees before or since.

On talking over the matter with a clever old gardener, still alive, he said he had often remarked Apricots set best in changeable weather. I have observed the bloom of trees which had been kept dry all winter had a dull and weak appearance, and have an idea that such extreme dryness is unnatural; but, of

course, this idea may prove incorrect, and if I prove it to be so you shall soon hear the result.

I think the tree in a pot mentioned by Mr. Rivers as standing in a narrow house with a Beech hedge at the back 8 feet high, and another in front 4 feet high, proves very satisfactorily that Apricot blossoms will stand a certain amount of frost, but not, I think, that they require to be always dry. Such a very imperfect protection would hardly insure the latter; nor do I think he is quite justified in saying, if he had lighted a charcoal fire in his orchard-house, almost every blossom would have set. Had he tried the experiment, and such had been the result, it would have been worth knowing. I am sorry I have no more positive information to convey on this interesting subject, but trust this gentle sprinkle will "lay the dust."—J. R. PEARSON, *Chilwell*.

THE PEAR CROP OF 1862.

As you ask for information respecting the Pear crop of 1862, I beg to offer you the following observations. There was an abundance of very strong bloom, and the fruit set very thickly; but the cold and wet in June and July thinned it considerably. The Pears did not appear to grow till August and September; indeed, I never saw the Pears and Apples grow so fast as they did in the latter part of August and all September. The soil, a very retentive loam, is very cold and damp, and the situation is low and damp.

The Pears are all grown against an east wall, except the Easter Beurré, and that is on a west wall.—E. SENDALL, *Burningham, near Cromer, Norfolk*.

Williams' Bon Chrétien.—Crop very heavy. Fruit medium size, and very good. Ripe middle of September.

Louise Bonne of Jersey.—A good crop; delicious fruit. Ripe beginning of October.

Forelle.—Crop good, but all the fruit that hung exposed were mildewed; the others were fine and delicious. Ripe end of October.

Marie Louise.—Very heavy crop. Fruit small but delicious. Ripe end of October.

Fondante d'Automne.—Crop middling. Fruit fine and very good. Ripe beginning of October.

Passe Colmar.—Crop good. Fruit small, and the best I have seen for ten years. They always mildew more or less. Ripe end of November.

Winter Nelis.—A heavy crop. Fruit medium size, and delicious. Ripe very early, and all done by the second week in December.

Beurré Diel.—A heavy crop. Fruit rather small, but very good. Ripe middle of December.

Glou Morceau.—A good crop. Fruit small, and very much mildewed; kept badly. Ripe in January.

Beurré d'Arenberg.—Crop good. Fruit delicious, medium size. Ripe throughout December.

Easter Beurré.—Crop good. Fruit very fine and beautiful. Ripe in December and January.

Beurré Bosc.—Fruit medium size. Ripe beginning of November. Not first-rate.

Ne Plus Meuris.—A very heavy crop. Fruit rather small, but very good. Ripe now.

NEW PEARS, THEIR VARYING MERIT ON DIFFERENT SOILS.

AT page 76 of THE JOURNAL OF HORTICULTURE, the well-known pomologist, "T. R.," gives us some account of Huyse's Victoria Pear, and says he tasted it on the 15th of January, comparing it with Joséphine de Malines; and from the comparison he pronounces it one of our best sorts. It is curious that the day before I read his notice I went purposely to taste the Victoria grown by a gentleman near here. We took Winter Nelis as our standard; but although the Victoria had the fine flesh, abundant juice, and melting qualities of one of its parents—Marie Louise, yet it was entirely wanting in the acidulous piquant flavour that so much distinguishes the Marie Louise, and it had not the slightest chance against the Winter Nelis. You see "T. R." and myself have chosen two Pears as our standards of excellence not easily surpassed; and it is not much to be wondered at that the Victoria did not rival the Winter Nelis; but how it reached the superlative Joséphine in one

locality, and yet in another place should be little beyond second-rate in flavour is worthy of inquiry, as it will in some measure account for the very different descriptions we meet with of the same Pear by writers on pomology.

As the fruit-room where I tasted the Victoria had not the light excluded, it would in a measure account for the flavourless state of the fruit (which were all ripe January 30th). Yet, locality, soil, and season have such wonderful influence on the flavour and keeping properties of Pears, that I think it well to state the fact of the Victoria being flavourless here this season, that purchasers of fruit may understand that it is quite out of the power of nurserymen to prevent Pears sometimes turning out the very reverse of what they describe them.

After tasting the Victoria, we tasted the Bergamotte Esperen, which we also found watery and with little flavour. Now, in nine places out of ten this, I think, would not happen with this sort, as I find it one of the best and most constant in its fine qualities, and one that bears profusely. No garden should be without so valuable a sort, more especially as it bears well as a pyramid, and is one of the best on a quince I know of. However, I find that all the fine-fleshed late Pears will be melting, juicy, and sweet upon light, warm soils, but will generally want that high, rich, buttery, and honied flavour which distinguishes some of them upon heavier soils inclining to clay.

The converse sometimes holds good with the coarser-fleshed kinds—a light warm soil very often brings out all their best qualities. A striking example of this I had here this season in Rousse Lench, which surpassed all my other sorts in luscious, honied sweetness, and rich, melting, buttery flavour. I should say that this sort is invaluable for light warm soils, being a profuse bearer and keeping until now (February). It is the latest hanger on the tree of any sort with which I am acquainted. Even when the leaves have all fallen, one will find the fruit still adhering firmly to the tree—a valuable quality in exposed places, as it is not easily blown off; and for walls I think it one of the best sorts known. Of course, such a late Pear would not do for the north of London, and, perhaps, not beyond Wilts, Hants, Beds, and Bucks.

"T. R." says he thinks that the Victoria will supersede the Glou Morceau and Beurré Diel. I think with him as to the first; but the second will not be easily dethroned in some localities on strong soils, although on light soils it will not be able to hold place with the Victoria. I do not know any Pear that varies so much with soil as does the Beurré Diel, nor any Pear that has such a range of the ripening period. With me this season it has extended from November to now (February); some fruit having fallen from the trees ripe, whilst others are now in my fruit-room and have no appearance of ripening, and possibly will rot and be worthless. On a pear soil about six miles from here it is one of the most magnificent Pears one would wish to possess, and although I had my grafts of the trees that bear these most splendid fruit—in all senses splendid—yet mine are not worth gathering.

Is "T. R." right, or is it the P. D. has made the mistake in saying that "the flavour of the Victoria is like the Prince of Wales Pear?" Should it not be Princess? (a little prematurely perhaps). I think the last was the name given by Mr. Huyshe to his third seedling. Quite a stroke of luck to obtain three such Pears from the same cross, and it shows how much may be done by judicious selection of parents.

To-day I have again tasted Easter Bergamot, and find in two specimens taken from the cold fruit-room that they are rich, crisp, and juicy; whilst a third taken from a warm cupboard is rich and nearly melting. The specimen described by me, page 29, was from a warm place, which generally much improves all late Pears. In cold or clay soils this sort would, undoubtedly, be as "T. R." says, "worthless."

As to Doyenné Goubault, the fruit from my specimen tree corresponds exactly with the description in the "Fruit Manual." I received my tree from Angers, where the sort was raised by Goubault, and the description given with it was, "First quality; medium size. Flesh rich, buttery, and melting. Ripe in October and December. Tree an abundant bearer."

And now to finish my long dissertation, allow me to recommend to the notice of your readers a new Pear, called Vauquelin, a very large and beautiful sort, with a fine, delicious, melting, and perfumed flesh, which is also rich and buttery, and just now ripe (February 2nd). I have as yet only had two specimens, but from their superlative qualities I think the sort will prove one of our best kinds.—J. SCOTT, Merriott, Somerset.

"THE FLORIST AND POMOLOGIST."

At the beginning of last year the pictorial journal so long known under the name of "The Florist" assumed a new title, and became "The Florist and Pomologist." The increasing taste throughout the country for the study and cultivation of fruits called for some more prominent recognition of this subject in a pictorial form than had previously been made; and in the new publication the same importance was given to fruits and fruit-culture, as to floriculture.

The volume of "The Florist and Pomologist" for the past year is now before us in its beautiful blue and gold binding, and whether viewed externally or internally, we cannot but congratulate the editors on having produced a very handsome and very useful book. The plates, of which there are twenty-three, are quite masterpieces of art, and convey the most faithful representations of flowers and fruits from the pencil of Mr. Fitch. As was to have been expected from the management under which the new periodical was placed, the success of the undertaking was complete from the commencement. We find in the pages of this volume thoroughly excellent papers on practical gardening by some of the most celebrated gardeners of the present day, and on all these grounds with great pleasure we recommend this excellent work to the notice of our readers. It is, indeed, a marvel of cheapness, with its two beautifully coloured plates, and sixteen pages of good practical gardening.

COTTON-SEED CAKE AS A MANURE.

ALLOW me to ask if any of my co-subscribers have tried cotton-seed cake as a manure? and if so, will they give the result of such trial?

My gardener assures me that it is valuable; that from a line of Potatoes on which he put 14 lbs. of cotton-cake, he obtained 68 lbs. of Potatoes, while farmyard manure produced only 33 lbs, the length of row being the same in both instances, and only 3 feet apart. I was induced to have it tried through reading a short paragraph in Mr. Johnson's work on agricultural chemistry. Naming the matter to a friend, he drew my attention to Mr. Alderman Mechi's work, "How to Farm Profitably." This gentleman speaks well of it and annexes a table drawn out by Mr. Lawes, who estimates the value of manure from animals fed on cotton-seed cake, at 20 per cent. higher than that from rape or linseed-cake.—A CONSTANT SUBSCRIBER, *Wilmslow, Cheshire.*

WATER-BAROMETER.

PERFECTION is not claimed. No weather-glass is faultless. But, it is believed, that the indications of this instrument are more truthful than those given by barometers in general use. Its cost is within the means of working-people. This consideration has induced one who has made experiments on what is an old principle, to make public the results of his experience.

The water-barometer consists of two transparent vessels—a flask and a hyacinth-glass. The flask is 10 inches high—5 in the bulb and 5 in the neck. The neck is, through its entire length, of half-inch diameter; the bulb being at its greatest breadth 3 inches through. The hyacinth-glass should be 7 inches and a quarter in height, and of such width as will insure stability. In the bottom of this lower glass there should be water, coloured by some dye, forming no sediment. The neck of the flask should be divided into 40 equal parts of one-eighth of an inch each on its outside, with figures 5, 10, and so on up to 40, 20 answering to "change." This scale may be made with any dark paint or varnish, by a small camel's-hair pencil. As soon as dry, the flask must be put upside down into the lower glass, so as to be suspended on the rim with its end submerged half-an-inch only in the coloured water. The instrument is then complete. The water will rise up the neck of the flask for fine, and sink for bad, weather.

This barometer should be placed in some room where neither sunshine, fire, gas, nor frost comes. It is but slightly sensitive to natural, but very much affected by artificial heat or cold. It will always move with the quicksilver, but will often alter for a coming change when the common weather-glass is obstinate.

In giving notice of a storm, this water-barometer acts very correctly. Fog does not affect it. North and east winds have in degree, but not in extent, the same influence on this as they have upon the mercury glass—they elevate the column. Rain

may also fall from high clouds, or from suddenly condensed mist, without much depressing the fluid. The existence of contrary currents of wind will often interfere with the working of all barometers. But, with such exceptions, this water-barometer may be depended on, as may be seen from a register of its movements carefully kept during the last thirty-two days. In this table the state of the mercurial barometer, the wind and the temperature, are given in order that a fair estimate may be made of the relative worth of the water weather-glass.

It should be added, that precision in the manufacture of the glasses is very important. A rough but imperfect substitute for the upper glass is a common Florentine oil-flask carefully cleaned out with soda. This was found out long ago. A more sensitive glass may be made, and of larger range, by contracting the diameter and increasing the length of the flask's neck, and then the lower glass must be higher in proportion.

The flask should be handled as little as possible, as the warmth of the hand depresses the column.—F. COPLAND, *Chelmsford*.

FIELD MICE.

YOUR correspondent, W. Hill, wishes to know how to destroy these troublesome little animals that are barking his Hollies. I beg to offer him the following suggestions to trap the mice:—Bore a number of holes all over the plantations about 20 inches deep, and wider at the bottom than at the top; these if baited and properly tended will catch great numbers. By all means preserve the barn owls and kestrel hawks, as they live on mice, and are in no way injurious to game.—B. P. BRENT.

CELERY CULTURE.

I NEVER missed having a crop of Celery yet, and my plan of cultivation is very nearly that of Mr. Hague's, though instead of plying the well-rotted leaves and refuse—the remains of a "muck-pie" hotbed over the roots, I place it under them in the trench, and I do not allow the plants to become thirsty for lack of house-sewage.

I bring the plants up hardy from the first. The mischief, I think, lies in too much coddling in the first going-off. Never let them know what bottom heat is, unless a few curiosities are wanted for the first shooting parties; and thin and prick out in time. Plant out with good balls of earth attached, and injure

the foliage as little as possible. I mentioned some years ago in these pages, that I save the Asparagus haulm to shade them on those occasions.

I am never in haste to mould-up Celery, but allow it to take a good growth, and then with a length of tar cord, and giving it a twist around each plant from end to end of the trench, they are placed bolt upright like a rank of soldiers, and the soil can be expeditiously moulded to them without danger of its penetrating to their hearts, which must be guarded against, and it is of very little use applying more liquid to them afterwards.

The sort I send is Coles' Red. It has never had but one moulding, for what with the International Exhibition, writing about that and other matters, the frost coming, and one thing and the other, moulding was afterwards neglected. Nevertheless, I have not had one rotten or bolted stick.

Our Aytoun Castle Leeks are very good; both the former and latter we use continually as stewed vegetables, and very wholesome and pleasant provisions they are either with brown gravy or white sauce. I cultivate the Leeks in trenches, constantly plying them with plenty of sewage, and mould them accordingly as they grow.—UPWARDS AND ONWARDS.

PLANTS OVER HOT-WATER PIPES.

CAN you inform me whether plants growing in long wooden boxes or troughs would be injured if placed immediately over the hot-water pipes which are carried round the inside of the conservatory? The boxes would be raised about one foot from the floor.—A.

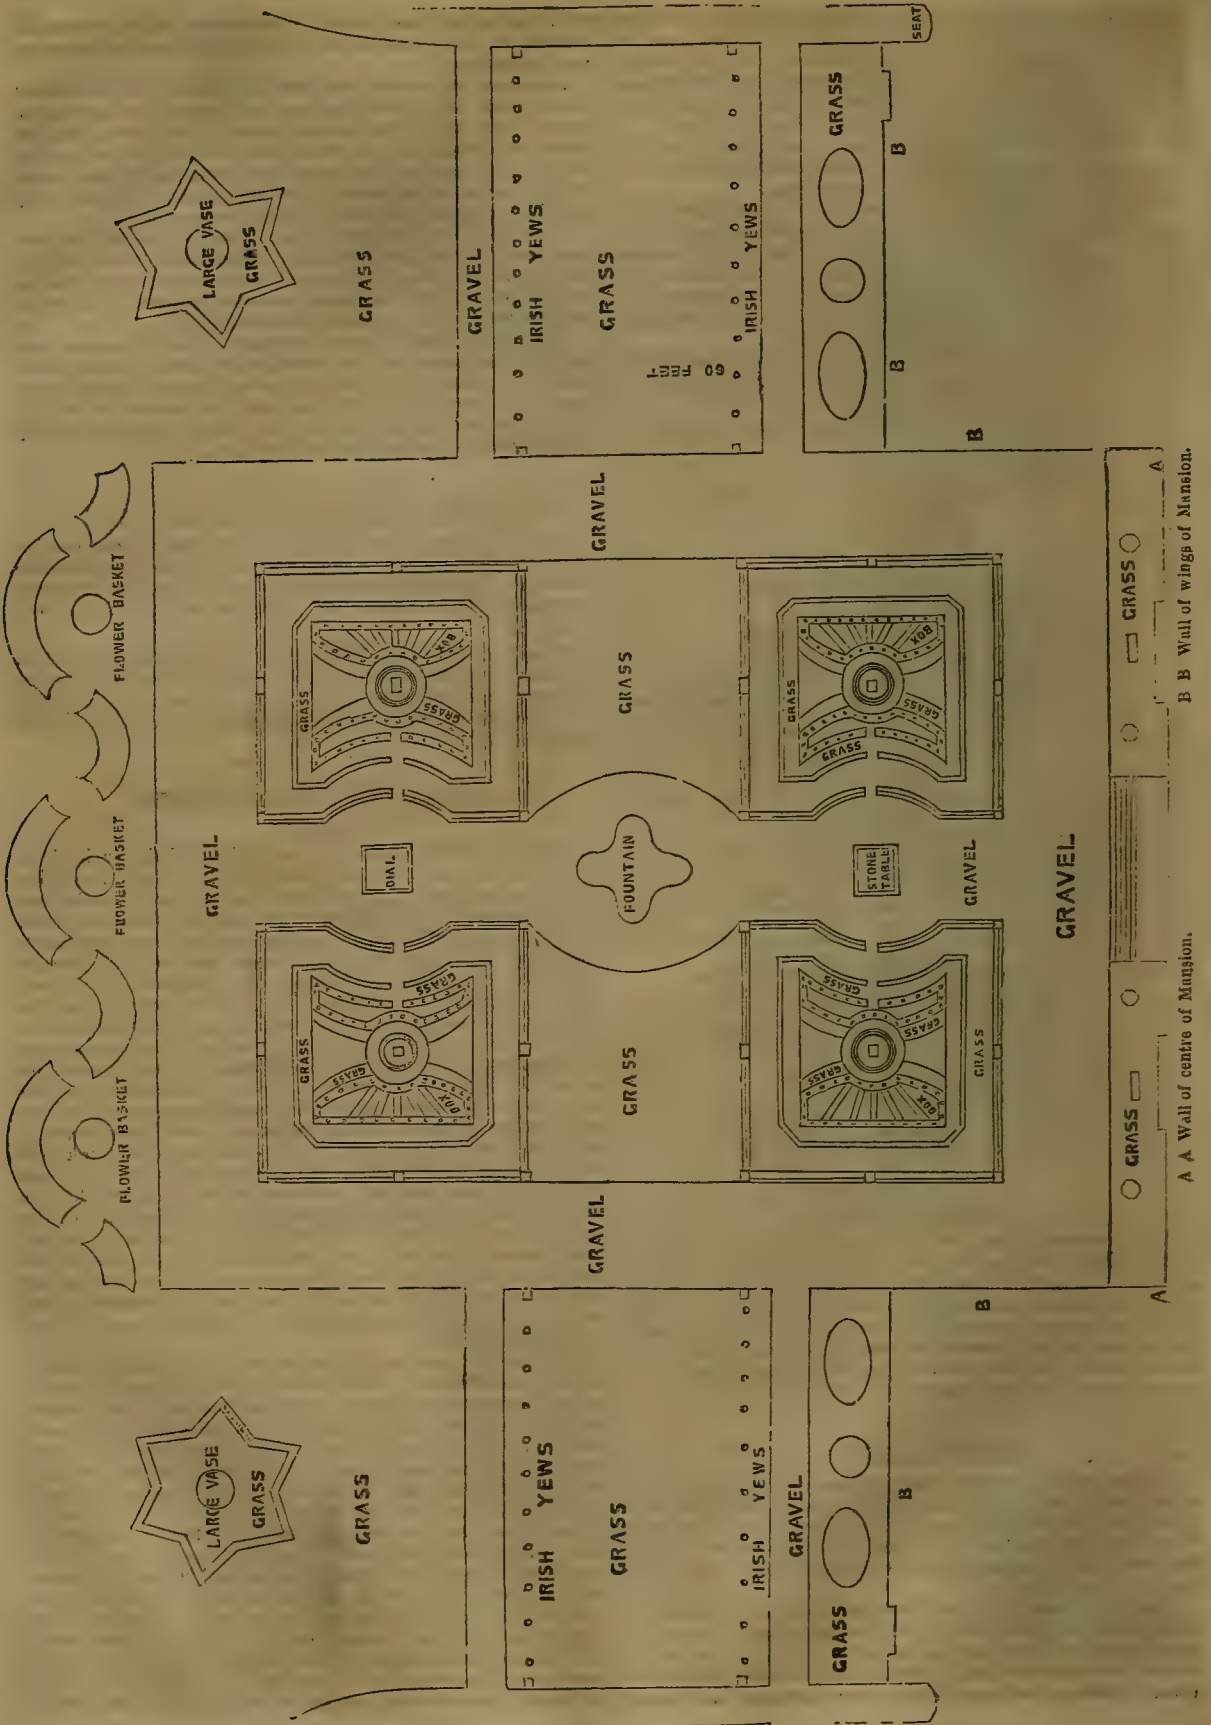

[It will be safest to put the boxes at the distance of a brick in thickness from the pipes, which will alike prevent over-heating the boxes, and allow free radiation of the heat from the pipes. Of course, blocks of wood would do as well, or even better than a loose brick.]

A FEW DAYS IN IRELAND.

CARTON.

THIS magnificent residence of the Duke of Leinster is about sixteen miles from Dublin and two miles and a half from Maynooth, so celebrated for its training college for the Catholic priesthood, and so interesting to the antiquary from its ancient castle, the ruins of which are so densely clothed with Ireland's evergreen—the Ivy. The splendid classic mansion of the premier peer and only duke of Ireland, was designed by Richard Cassels, and will long remain a monument, not only of the purity of his taste, but of the ideas that must have been entertained by him of fitness, utility, and comfort. In passing many a noble structure, the idea of magnificence is often lowered by reflecting that within the walls so many human beings pass the most of their working hours beneath the ground level, in comparative darkness, and where scarcely one direct beam of sunshine can ever penetrate. People will begin to think now that the circumstances and conditions that may be the very best for keeping wine and ale, may not be the most suitable for securing the health and promoting the cheerful activity of the industrious workman. It did seem to be in unison with the benevolence of the noble peer, standing as he ever does in the van as respects all means of improvement, to see at a glance that from the uses to which the wings of the mansion were chiefly applied, his servants could have access to sun and air equally with himself.

The building consists of a centre and two projecting wings on the garden front. With the exception of a beautiful portico in the centre of the entrance front, and one bold break besides on each side, the mansion extends in a straight line for some 400 feet. On the garden front the length of the centre of the house is 220 feet, mean breadth 56 feet, width of wing on each side of this centre 68 feet, length of each wing on each side 85 feet, continued to alcove 35 feet, making 120 feet for length of each wing, and length of garden front 460 feet, breadth of each wing across courts and main buildings 124 feet. In the centre of the garden front is a noble portico, 30 feet by 18, with a flight of some six steps also 30 feet in length. This opens on the left side into the library 46 feet by 19½, and farther still to the left are the reading-room and the Duke's private room. On the right-hand side are the drawing-room, 35½ feet by 19½, a good-sized ante-room, and a very fine dining-room, 52½ feet in length, 24 in breadth, and 24 in height. The left wing is

chiefly applied to the rooms necessary for attending to very superior stabling. The right wing is chiefly devoted to rooms for the house-steward, housekeeper, kitchens, &c. Each of these wings has a suitable entrance at its end. These two wings are connected with the centre by a colonnade or conservatory on each side, each 43 feet by 10.

If flower-gardening were to be attempted at all in front of such a magnificent building, it seemed to be required that its characteristics should be simplicity, uniqueness, and elegance. So far as we could judge from our short visit, these have been thoroughly secured, and by a mode not more simple than uncommon. Leaving lesser matters out of consideration there are two grand features. First, four square or parallelogram gardens bounded by low Yew hedges, in front of the centre of the mansion. The first pair is next the portico. The second pair is separated from the first by a breadth of grass of 60 feet. This grass is extended, but wider, 300 feet on each side, making with the centre of 220 feet, 820 feet in all. This forms the Irish Yew avenue—the second grand feature—the trees standing 60 feet apart across the avenue, and, therefore, on one side in a direct line with the farther boundary of the first pair of gardens, and on the other side in line with the nearer boundary of the second pair of gardens.

Through Mr. James's kindness we would have given a large plan of these unique gardens, but have been obliged to give a very condensed one to suit our page. With that plan, however, and even without it, our youngest reader may easily make the main outlines for himself by the following simple details. Take a straight line across in front of the steps of the portico, which will leave about 17 feet between it and the mansion for grass lawn, and three clumps for flowers on each side. Then from this line take another close to the wing, on each side and beyond it, measuring altogether 262 feet. Cross that at the farther end, and you have a parallelogram 262 feet by 220. Come back again to the line of the portico, and measure from that line of grass 28 feet for gravel. Take the same width along each side, and across the farther end, and thus you have another parallelogram less by 28 feet at each end and the sides than the first one. Divide this longitudinally again, just opposite the portico, by another walk of 28 feet, and you have now two equal-sized parallelograms bounded by gravel all round. Lay-off in the centre of this piece of ground longitudinally, which we have seen at first was 262 feet, a space of 60 feet transversely for grass, unless where the three walks pass through it, and then you will see that that grass avenue and the different walks will leave two parallelograms next the mansion, and two beyond the grass avenue, each of which will be 68 feet in breadth and 73 feet in length. As already stated, the Yews in the avenue are 60 feet apart transversely, the same width of 60 feet extending for 300 feet on each side.

As described, each of these parallelograms would have straight sides but for good reasons. One of the four sides of each of these gardens is curved in the middle where the entrance to each is, which is about 5 feet in width. These entrances are from the middle walk, and those of each pair opposite each other. Even at the middle walk the straight square form is maintained at each end for 16 feet, and is then curved towards the centre opening, so that the width of gravel there, from one square to its opposite neighbour, is 36 feet instead of 28 feet. In the centre of this wide space next the mansion is placed a massive stone table, and in the similar space farthest from the house there is a sundial; and the propriety of the arrangement we shall presently see. We may just state here that in the centre of the same central walk, with the 60 feet of grass on each side, is an elegant fountain with lofty statuary, and here the grass is swept out on each side so as to give, across the fountain and gravel, a width of 50 feet.

The external arrangements of these four parallelogram gardens are the same. It will have been seen that one side of each of the four will abut on the central avenue of grass of 60 feet wide, the other three sides will come against these twenty-eight-foot walks of gravel. To prevent this there is a verge on these three sides of about a foot of grass. The outside of each garden is then bounded with a beautiful Yew hedge 20 inches in height and 18 inches across. A grass lawn 8 feet in width separates this hedge from a second hedge of the same size and equally well kept, and then a grass walk of about 4 feet separates the second hedge from the centre, devoted to flowers.

In the centre of each of these gardens is an architectural pedestal 2 feet square, and 3 feet in height, and surmounted by

suitable statuary, also 3 feet in height. At each of the four outside corners of these gardens, and in the centre of the three sides—that is, on all sides, except where the entrance is situated, is a pedestal 2 feet square, and 40 inches in height; the pedestal being partly in and partly outside the Yew hedge, so as to show clearly. On these pedestals are beautiful vessels in the basket style, which when we saw them, in September, were filled with Scarlet Geraniums and other plants, and in winter are chiefly filled with Box trees about 18 inches in height. Whether for summer or winter decoration the plants are placed in small suitable tubs, and these are slipped inside of the baskets, and now we see there was more designed than mere variety of outline, in the widening of the central walk opposite the entrances to these gardens. To balance each garden and render it uniform, there should have been eight baskets instead of seven. The eighth could not be placed on the inner side, on account of the entrance-opening; but the table in the centre of one pair of gardens, and the dial in the other, come in very nicely as a compromise to the claims of balancing and uniformity.

These central statues, with the lofty one at the fountain, the dial, table, and twenty-eight baskets, gave a very striking, rich

appearance to the whole scene, increased as that was by the uniqueness and the dark colour of the Yew boundaries. As far as we recollect, each garden was arranged differently. The pedestal in the centre of each was free, as it ought to be, and surrounded with a ring either of grass or gravel, and narrow walks of one or the other up to it. Some of the gardens were balanced in either direction. In others, as the one engraved, this had been disregarded, and the picture was to be looked at as a whole, instead of in quarters or parts. Whatever the ground plan, the carrying-out of the arrangements reflected the highest credit on the skill, culture, and taste of our new friend, Mr. James. It would be endless to describe the planting of the larger and smaller beds, especially without plans; but three features seemed to be prominent: First, the contrasting of the larger beds with bright colours; secondly, the mixing of such Geraniums as Lady Plymouth and the old Scarlet Variegated with *Verbena venosa*, or the Flower of the Day with Purple King, which were done to perfection; and thirdly, the surrounding the outsides of the group with dotted pearls—such as having *Verbenas* Purple King, Pulchella, Manetti, &c., for ground colour, and spots regularly dotted with Alma, Flower of the Day, &c.; or the ground colour would be white, as these Geraniums or Variegated Alyssum, and the spots purple or scarlet.

Before noticing the avenue, we may mention that in front of each wing of the house lengthwise is a piece of lawn similar to that in front of the main centre, then a walk some 8 feet, and lawn beyond, going on to the 60 feet between the trees. This Yew avenue is a grand feature, extending 300 feet on each side of these central gardens, and the baskets in the Yew hedges coming in a line with these specimen Irish Yews, making the avenue altogether 820 feet, and backed by a border of Hollyhocks

and Dahlias, and then a row of Cedars, 40 feet apart. The Yews in this avenue are 10 feet from plant to plant, and average from 10 to 12 feet in height, each plant being a straight, well-rounded, massive, healthy specimen, which carries much cultural care and constant attention in its appearance.

The grandeur of this avenue is, if anything, heightened by the ground on the right-hand side of the mansion rising somewhat abruptly by a large mound having been made there, which conceals a drive leading to the mansion and offices. Besides the fountain and the statuary already referred to in the middle walk of the Yew gardens, and which is thus in the centre of this avenue, colossal figures in bronze either are or will be placed near each end of the avenue. Besides shrubs at the mound at the side farthest from the Yews, there was a ribbon-border in front of the shrubs, beginning with Hollyhocks and Dahlias, a row of Crystal Palace Dahlia, then China Roses, then Kentish Hero Calceolaria, followed by Scarlet Geranium, then Verbena venosa, and fronted with Manglesii Geranium. Here the row of venosa was very nice, and told well, and the Kentish Hero, an old favourite, was the best we have seen for years. After having had it in grand perfection, it became so liable to the black spot with us, that we were forced reluctantly to give it up.

The whole of the extensive lawn on this avenue, and far beyond it, was in excellent keeping, looking as if it were rolled every day. The wide walks were clean and firm, and the flower-beds, notwithstanding the rains, were in fine order, testifying to a very high style of management; and whatever may have been the case at other times, not a workman was to be seen during the forenoon of our visit. This last fact is often of more importance than is generally imagined, as far as respects the pleasure of the proprietor and his visitors, and the comfort of the gardener. Much may be done by having work near mansions finished before breakfast, so that all may be cleared-up before visitors walk out. At the farthest end of these Yew gardens is a small parterre of baskets and clumps on grass, next the park, and in some of these were tall Hollyhocks, which were all that we would have wished altered under the present arrangements. They did look staring and solitary against the sky outline, or the distant background of groups in the park, and so different from what they appeared in other places, with a green background behind them.

The arrangements of these Yew gardens, besides their uncommonness, seemed to secure three advantages: First, little of the flowers in the beds could be seen unless from the higher windows until you came pretty close up to the beds, and this will always enhance interest and pleasure; second, the double low wide hedges, and the amount of grass, and the plants in the basket would give a finished appearance in winter, even if the beds inside were unplanted; and in this respect there would be an advantage over sunk panels in such a place unless these were carefully planted in winter; and third, no flowers, except those in the raised baskets, coming in prominently before the eye, there would be little but these to divert attention from the park scenery beyond when it was desirable to concentrate attention upon it.

That scenery is very pleasing and attractive, the park being very large, the trees beautifully grouped, and the woodlands massive and well managed. Though the surface when examined is undulated and varied, yet for a great extent of country the prevailing features from a distance are levelness, richness, luxuriance, and abundance, with but little of the bold romantic picturesque which abounds in many parts of Ireland. Amid scenery so beautiful, but somewhat level in its beauty, the mind seems to long for some elevated points on which the eye could repose; and just as if to meet such a craving desire, there is a high tower at one place, and a lofty pillar at another, which, for many miles, form well-defined landmarks. R. FISH.

GRANT THORBURN.

WE regret to announce the death of Grant Thorburn, of New York, at the advanced age of 90. Mr. Thorburn was the founder of the extensive seed establishment now known as

J. M. Thorburn & Co. He left Scotland in the year 1794, and after a successful career of honourable industry, and a life devoted to the welfare of his fellow citizens, with whom he was held in high estimation, he retired from public life some years ago. In our next we shall give a sketch of this extraordinary man.

SOWING POLYANTHUS SEED.

BEING an ardent lover and successful grower for more than forty years, of that early spring flower, the Polyanthus, I thought a word or two on its cultivation at this season of the year might be acceptable to many amateurs who have been unfortunate in its culture, having heard many persons say, "I admire the flower, but cannot get the seed to grow. I have taken great pains with it, placed the pans in a greenhouse, and waited a month or five weeks, and yet no plants have made their appearance, and then have thrown them on the dung-heap." Now, if they had waited a few days longer they would have been rewarded for their trouble, as the seedlings seldom make their appearance under six weeks.

Others have set their boxes in the sun, where in two or three hours, if the seeds had begun to germinate, their labour is all lost, for once dried in that state they never recover; but if the amateur will attend to the directions I am about to give, he will find a one-shilling packet of seed will give him two hundred plants, and from that quantity he may calculate to get from twelve to twenty first and second-rate flowers that will not disgrace a florist's stage, and the remainder be good border flowers.

I generally sow my first seed early in February, in the front of a cold pit, where little or no sun comes on them. These produce, generally, my best and strongest plants. In March, or earlier, I make my next sowing in the open air, in a shady border, making the soil as fine as I possibly can with a rake, and sow my seed, taking great care to put no more fine mould on the seed than will cover the face of writing paper, and put on a few small bushes or brakes to keep the wind from drying the earth, and ease the water given from the pot, as in no instance must the seed be allowed to get dry. Thousands of plants are lost for want of that precaution. When large enough to handle, plant the seedlings 3 inches apart in a shady border.—JAMES WOODS, Harwich.

VENTILATION.

I NOTICE in your paper of the 20th ult., a letter from your well-informed correspondent, "D., Deal," in which inquiry is made as to ventilation in a hothouse he purposes building, without having sashes on the roof to open.

I have just completed two vineries with a like object in view; describing one will answer pretty nearly for both.

The house faces a little to the east of south. It is 75 feet long, 16 feet wide within, the front from 7 to 8 feet high, and the back wall from 12 to 13 feet high. The roof and front are glazed with large-sized squares in iron bars on rafters. It is well drained, and has a flooring of concrete covered with 20 or 24 inches of soil, &c., for the Vines to be planted in. The bed of soil extends from the back wall to 20 feet in the front, and small arches under the front wall allow the Vine roots to spread in all directions. The house is heated by 10-inch drain-pipes serving as flues; the first 12 feet from the fire, being walled with firebricks. The house is divided by a glass partition into two unequal parts—that nearest the fireplace intended for Vines, and the smaller, 30 feet long, for an orchard-house; a flue continued through the latter can be used or not as required. A pit, with an eight-inch flue passing under it, laid in broken bricks, &c., used for a Melon or Cucumber-bed, fills up much of the centre of the vinery. The brick wall in front shows about 4 to 6 inches above the soil. On this wall I have wooden ventilators of 8 inches depth, the whole length of the house. There is no opening whatever in the roof; but immediately under the top part of the roof is a row of ventilators opening into the wall and out again in front under the projecting flaps on the top of the wall.

Generally in hothouses manure is laid on the borders, but this cannot be forked in more than from 3 to 4 inches deep, lest the roots be injured. I was desirous of supplying mine much deeper, and had round drain-tiles made 20 to 24 inches long, and 4 inches in diameter, perforated with three rows of holes

running parallel and on one side only. These I have placed with the holes downwards, lest they might become filled with earth. The drains are laid in rows 4 feet apart, from the back wall to the extremity of the border in front, each drain thus being from 36 to 40 feet long. Each junction of the 20-inch pipes is supported by a brick 12 inches long, placed on its end, not to occupy too much room in the border. These rows of drain-pipes have openings to the surface by junction tile-pipes placed perpendicularly at the extremities, and at one or two places in the middle.

I had two objects in view in constructing these drain-tiles, or, rather, I should call them supply-tiles. I can supply the roots of my Vines with any quantity of liquid manure, and can also admit or, stopping the drain ends, exclude the outward air.

If "D., Deal's" only object is additional supply of air, I would recommend drain-pipes of 10 inches in diameter, as the air will circulate in greater quantities and more freely than in smaller pipes. As his hothouse has glass only at one end, a good-sized triangular window at its upper corner would cause much air to circulate from the openings at the bottom ventilators and drain-tiles. I have these windows in both ends of mine.—EDWARD SWAINE, *Crescent, York.*

[The arrangement of the flues we must approve of, as they are just what has been so often recommended in these pages. Your mode of ventilating at top is much the same as that described by Mr. Fish as existing at Rockfield, near Kells; whether it will be sufficient or not will depend on the size of the ventilators. Even with the windows at the end, a foot opening would be necessary, unless a large amount of air is admitted through the drain-tiles that pass beneath the border. This plan was also adopted at Rockfield. Though we approve of this mode of ventilating at top, chiefly because the air is much mollified before entering the house, we cannot recommend it on the score of economy, as a simple hinged ventilator at the apex would be much cheaper than these openings in the back wall, coming out beneath a top coping. You would also find that the mode of taking air through the border was practised at the gardens of the Vice-Secretary, Phoenix Park, Dublin. On the whole we generally approve of your arrangements; with enough of top air you will be all right.]

HORSE CHESTNUT.

I AM induced to write this letter from the observations made in your last week's Journal relative to the name of the Horse Chestnut.

The prefix "Horse" is not, I think, as Gerarde imagines, because horses may have been fed or physicked on the nut, or to denote its powerful flavour; but from the simple fact that at every joint in the branches is an exact resemblance of a horse's foot, and not only the foot but the fetlock-joint, the pastern, hoof, shoe, and even the nails.

All persons whose attention I may have called to this fact have expressed themselves equally surprised at the correct likeness to the horse's leg and foot, and that it should not be more generally known.

I have enclosed one that is lying at hand, and although it has been cut off some time and is not a good specimen, yet it will show you at once what I mean.—B. B.

[This illustration is a very good one, and we have others in our possession with a very close portrayal of the knee and fetlock-joints, pastern, hoof with nails of the shoe, and frog; but we do not think such resemblance originated the name. We believe, as we said last week, that the term "Horse" was prefixed by our ancestors to anything that was a coarse resemblance of something else, as "Horse-radish," "Horse-laugh," "Horse-cucumber," "Horse-mint," "Horse-play," &c.—EDS.]

IMITATION OF GRANITE.

HAVING read an account of the result produced at Woodstock by mixing granite with Portland cement, I should be obliged by your informing me how it was used, and what gives the appearance of stone to such buildings in London as the Great Western Hotel, which is, I believe, only Portland cement. Is it a wash of sand applied to the last coat?—A SUBSCRIBER.

[The result obtained is very different from any mere covering with cement, and then drawing the surface into the resemblance

of blocks of stone. This, of course, is done by Mr. McDonald, but the granite appearance is given by the mixing. There is, however, a feeling of delicacy and a sense of regret as to giving the minutiae of details. Our correspondent is quite right in asking, and in the legitimate way, through our Editors. Other inquiries have come in a private way desiring answers to be given in our serial, as to the expense of granite polishing, and the very minutiae of the treatment of those Vines so summarily dealt with; one gentleman saying he cannot see how such severed Vine-stems with merely a few inches stuck in the ground, could be made to grow and fruit under any ordinary treatment. Of course they had more than ordinary treatment. I can pretty well see every move that was taken, but then I did not actually see the moves. No class of men have ever so freely communicated their experience for the general benefit as gardeners, and too often with but spare thanks for their liberality. A friend told me the other day, "We are used like an orange—get well sucked, and then are treated as the rind is." We have little of the morbid, and do not believe we could keep anything like a secret of our own, if we tried ever so much. We think, however, that the owner of the orange should have the privilege of squeezing out the juice; and as Mr. McDonald is sure to see this, we must leave the minutiae to be dealt with as he judges best.—R. F.]

VERBENA CUTTINGS.

Is it generally known that Verbena cuttings will strike in sand equally well and quickly with or without a second joint below the surface? If not, it should be made known, as the number of cuttings made available by this means is very much increased. Also, I may state, that early in October I put a pan of cuttings in this way, and although the frost had previously nipped them, they were all well rooted at the base of the cut (not from the joint, though that was below the surface of the sand), early in December. They stood in the greenhouse, a cool one, without any glass, &c., over them, and the only attention given was keeping the sand moist.—H. C. K., *Rectory, Hereford.*

[The above fact is well known, also that every Verbena joint will make two cuttings by splitting the shoot through the joint; but it is useful to remind people of such things at this season. We thank you for the hint, and we shall enlarge on it soon.]

ICE-HOUSES AND ICE-KEEPING.

HAVING had some experience in ice-houses and ice-keeping, perhaps that experience may be of use to some of your readers.

I have assisted in filling several large ice-houses—those built in the usual way in the form of an egg with brick and stone, which must have at least from 400 to 600 lbs.; and it was only in certain seasons that the ice kept longer than August, even when none was taken out for use—partly, I think, because they were not large enough. It was certainly the case with the one here, and which was done away with owing to alterations which were made on the ground near it.

Seeing the failure of the expensive brick and stone one, my employer was determined to try one of the form that the Canadians used, made of wood. It was put up exactly according to plan and specification, and cost somewhere about £40 or £50. It held about seventy-five or eighty Scotch cartloads. It certainly kept ice better than the old one, but not sufficient for a full supply.

Within a few yards of this house was a long hole 26 feet in diameter and 5 feet deep—in fact it was the first hole made for the Canadian ice-house; but the sides slipped in before the framework could be put in, and it was thought the best and easiest way to make another, where only two sides of the hole had to be dug. Previous to its falling-in a drain had been made to take away the water, and three feet of sandstones had been put in the bottom for drainage.

After filling the ice-house, and having plenty of ice, we smoothed down the sides of this hole, and filled it with ice, thinking it would supply the demand throughout the summer and reserve that in the ice-house; but it turned out that the stack supplied all the demands of the family, and we had ice there when it was all done in the house. We kept filling both for five years with the same results, until the wood of the house was completely rotten, and which would have required to be

renewed again in that short time. But for these ten years past we have had abundance for the cook, butler, and dairymaid all the summer. We have now at least thirty cartloads, and last year the same.

The hole when empty holds 170 or 180 cartloads, but 80 or 100 cartloads, in addition to what was remaining in it, have filled it for some years past.

The carts are not large, or rather they are not loaded with more than what lies easily on, as we have only 40 yards to cart it from the pond to the stack. Two carts are used, and fourteen or fifteen men fill the hole in a day. The carts, when the ice comes up to the level of the ground, are driven over the top of it, and eight or ten men are kept breaking it with wooden mallets. When the ice is so high that the horse cannot get up, it is thrown up with shovels as high as it can be raised, and then covered over with straw laid on about 2 feet thick, in bunches and made a little smooth; a few straw ropes are thrown over this, and these ropes are tied to a piece of stick at each side to prevent the wind from blowing away the straw. Both the ice-house and stack are in a plantation shaded from the sun with large trees. The soil is a wet, cold, clayey gravel. Whenever I see frost set in I remove all the straw from the old ice, and clean all the ground about it, that the soil may be all hardened by the frost. This enables us to keep the ice clean.

Had I been disposed to enter into the theoretical principles of ice-keeping and to spin a long roundabout article on the construction of ice-houses, ventilation, &c., I had here a good opportunity, but I think it of more use to keep to a plain statement of facts; and from what I have observed here, if ever I were asked the best way to keep ice, I should reply, Let it be kept in any such hole as I have described where there is drainage to take away the water, shaded with trees if possible; or add more straw, for drainage could not be had then on the surface; but in that case it would be more expensive to get in, as it has nearly all to be thrown up with shovels, whereas in the hole a comparatively small quantity is required to be thrown up with the shovel.

The pond from which we procure the ice contains a superficial surface of 1000 yards. When the ice is 4 inches thick that on the pond fills the stack, which gives us the above number of cartloads—170 or 180. On one occasion we had a fall of snow of about 3 inches, which was partly wetted and then slightly frozen again on the top of the thick ice, when 130 cartloads were only required; as more could be laid on each cart, the half-melted snow causing it to lie better on the cart. Thus, in order to give a correct idea of the quantity of ice put into a stack, much depends on the size of the cart and the state of the ice. A thousand yards 4 inches deep give us 111 cubic yards of solid ice to put into our stack, and this supplies all demands made upon it, and no less quantity need be attempted with anything like success. I would say that in England, where the temperature during the year is higher than here, it would take 20 or 30 cubic yards more to be secure against all contingencies.—ALEX. SHEARER, *Yester*.

NEW BOOK.

English Botany; or Coloured Figures of British Plants. Third Edition. Edited by John T. Boswell Syme, F.L.S., &c., with Popular Descriptions, by Mrs. Lankester. London: Hardwicke.

THIS is a re-issue of the work long known as "Sowerby's English Botany," with additional plates of the species, or forms of species, which have been discovered since the last edition was published. In addition to the figures of the plants themselves, some of the plates are furnished with new dissections of the floral organs, and the fructification; and in this respect we should have expected to see illustrations of a more modern character than those that are adopted. Botanical illustration has in these latter days made as great progress as the science itself; and we certainly expected to have seen these dissections treated somewhat after the style of Fitch in the "Botanical Magazine," and by many of the continental artists, instead of the old-fashioned and contracted manner of those of the last century. Let us take, for instance, Plates ii. and iii., in which, with the exception of a fruit and a stamen, all the other figures are of the natural size; a single flower no larger than those better represented on the panicle, a calyx of the same dimensions, and a figure which even a pocket lens is no assistance to enable the uninitiated to

determine what it is intended to represent. If single organs are worth figuring at all they should be done on a scale which enables every detail to be shown—as, for instance, the section of a flower three or four times the natural size, showing the pistils, the insertion of the stamens, and the apicular anthers. Then there might be a section of an achene exhibiting the situation of the small embryo in the large mass of albumen: these would be illustrations at once instructive and valuable; but those that are given on the plates might just as well not be there. The figures of the plants themselves are, however, unexceptionable.

The botanical part of the letterpress has been undertaken by Mr. J. T. Boswell Syme, lecturer on botany at the Charing Cross and Westminster Hospitals. Mr. Syme is well known in botanical circles as an accomplished British botanist, and the way in which he has performed his task in the first Number of this re-issue will not detract from his reputation. He has evidently entered on the work with all his might, and he has performed it most ably. Mrs. Lankester takes the popular and historical portion, and she furnishes some agreeable information.

The work is arranged on the Natural System, and will, when completed, be a valuable addition to British botanical literature. The Number before us contains twenty-four plates of plants belonging to the order Ranunculaceæ.

WORK FOR THE WEEK.

KITCHEN GARDEN.

BEFORE the general routine of cropping commences mark out all the divisions, so that two crops of the same sort may not follow each other. It is a good plan to label every crop when sown or planted, so as to refer to afterwards. *Cabbage*, fill up any vacancies in the autumn-plantation; also, make fresh plantations of the autumn-sowing if necessary. Old Cabbage-ground which has been under sprouts since last August will now become available for other purposes. Where plenty of Coleworts have been provided, some of the latest of the July sowings will supply their place and stand over for early Cabbage. Old Cabbage-ground should be trenched and pretty well manured, as the Cabbage is a scourging crop. The general system is to follow with a second sowing of Peas, the Peas in their turn being succeeded by Celery-beds, and this course prepares again for any of the Brassica family. *Cauliflowers*, those under hand-glasses and in frames must be fully exposed during the present mild weather, or they will button-off in the spring. Sow seed on a south border to succeed the autumn-sowing. If any have been potted they may now be turned out of their pots, putting five strong plants under each hand-light. See that the spring-sown do not "draw;" if raised on heat, let them be pricked out betimes. *Celery*, sow seed in boxes, and place them in heat to produce plants for an early crop. A portion of the old may be taken up to check running to seed, and laid-in by the heels very deep. *Garlic* and *Shallots*, where the soil is not wet and stiff, they should now be planted, if not done in the autumn. Plant in rows at 6 inches apart. *Lettuce*, those in frames must have the glasses off them day and night while the weather continues so mild as it is at present. Make a sowing on a south border to succeed the autumn-sowing. *Peas* and also the *Beans* sown in pots or boxes to be hardened by degrees in the cold frames, preparatory to transplanting to the open ground. *Rhubarb*, pots may now be placed over the roots and covered with dung or leaves. *Spinach*, a small sowing of the round sort may be made between the rows of early Peas.

FLOWER GARDEN.

The plans for the coming season of gaiety should now be fully settled. All alterations should now be carried out without delay. Now is a fine time for the formation of beds for Bourbon, China, and Tea-scented Roses. These classes of Roses will bloom throughout the summer and autumn months. To have them in perfection it is necessary to take the soil out of the bed 1 foot deep, and to fill-up with rotten dung. Tread it firm as the bed is filled-up; place 3 or 4 inches of soil on the rotten dung, and plant in the usual manner. Prepare the Ranunculus bulbs for planting by removing all small roots. These should be immediately planted by themselves, and as but few will bloom the coming season, they will gather strength and size for the next. In arrangement diversify the colours as much as possible, and as there is such a great diversity, the character of which is now described in most catalogues, it renders the amateur's task comparatively easy. See to even small plants

being secured against wind, for these are often injured by being blown about, especially if recently transplanted, and a small stake and a few minutes' work would prevent the mischief.

FRUIT GARDEN.

If any root-pruning of fruit trees has yet to be done, let this be attended to without further loss of time, and see that trees exposed to wind are securely staked. Take every opportunity of pushing forward pruning and nailing. The extreme mildness of the present season will induce an early bloom on fruit trees. Hasten the spray of evergreens, beech branches, or spruce fir, or suspend straw ropes, &c., in front, as in all probability we shall have winter in March or April, and, the more retarded wall trees are, the greater chance will there be of a crop. Watch the smaller kinds of fruit trees—as Gooseberries, &c., and if liable to have their buds eaten by birds, dust them frequently with soot and lime.

GREENHOUSE AND CONSERVATORY.

Select young plants of *Boronias* and other New Holland plants, and give them a good shift. They delight in good fibrous heath soil in a rough state with a good portion of sharp sand and rubble or stones, with charcoal placed over the drainage and some good-sized pieces placed among the soil as the potting proceeds. The plants now potted to have the bloom picked off as it appears, and the shoots duly stopped as they make their future growth. Select the Heaths that require fresh potting and treat them as advised for the New Holland plants.

STOVE.

Commence the application of more heat in moderation. Make use of the syringe every fine morning pretty freely, except on those plants that are in bloom. Select some of the best young plants of *Euphorbia*, *Brunfelsia*, *Jatropha*, *Rondeletia*, &c., and place them in bottom heat. Cut back *Poinsettia pulcherrima*, *Eranthemums* of sorts, *Justicia coccinea*, &c. Shake out and pot in good, open, fibrous loam half decayed, with some sand and charcoal, the tubers of *Gloriosa superba*, and place them in bottom heat. No water to be supplied to the tubers until they have commenced their growth. This is a beautiful and very curious plant when well cultivated. Keep a watchful eye on the *Orchids* now commencing their growth, and see that there is no water from drip lodging for any length of time between the partly-unfolded foliage and partly-formed pseudo-bulbs. Syringe with tepid water the sides of the baskets, blocks of wood, &c., that have *Vandas*, *Saccolabiums*, *Arides*, *Sarcanthus*, *Stanhopeas*, &c., suspended or growing on them.

PITS AND FRAMES.

Shift those *Petunias* and *Verbenas* into larger pots from which cuttings are to be taken for the next two months. Make a sowing of *Phlox Drummondii*, and place it in a hotbed. Sow also, in a mild hotbed some Ten-week Stocks, *Asters*, and other half-hardy annuals. Give abundance of air at all favourable times, and endeavour to keep the air of the pits and frames as dry as possible. Water sparingly here at present, not using any if the plants keep healthy without it. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

FOR general matters see last week. Took occasion of a dry morning to wheel a little, as it is very undesirable to make work whilst doing work. We have often seen a wheelbarrow taken over a nice walk, and with a dirty wheel too, and the necessary cleaning-up wasted more time ten times over than the carrying the material in a basket would have required. Trenched-up ground where there had been two wide beds of Celery; the space having been previously occupied as temporary beds for bedding plants. Trenched or, rather, ridged it across that the dung at bottom might be spread equally all over; but to our mortification found that the bedding plants and the Celery plants had pretty well eaten-up every particle we had given them. To do this, a large part of one bed had to be taken up with good roots, set closely together, and earth trundled on to the necessary height. We sometimes set in earth, water a little, and then pack to the top with litter. If taken up late, and not watered well, the heads will be apt to bolt. We are sorry that so many were disappointed with Celery this season. We do not think we have had five bad heads since September, and almost the whole was the Dwarf White Incomparable, which, if it is 15 inches in height, will give you 12 inches fit for table, and is just the sort for the

amateur and cottager, as it needs so little room. We had four and five rows across in beds about 4 feet wide. No Celery can be crisper or sweeter, though of course you do not make your friends astonished by looking at huge mounds and plants 4 feet or more in height, and as thick in diameter as a man's thigh, and with no such wondrous hearts after all. There were a few grubs on the leaves which were picked off, and soot and a little resinous sawdust thrown over the plants to prevent the fly depositing more of its eggs. Have sown for the first crop; have sown other years before Christmas, and had no run heads. The mere time of sowing has little to do with it; that is solely the result of checking the plant before planting-out, and giving it anything but natural treatment afterwards. Sowed more Dwarf Kidney Beans in heat, a few Broad Beans under cover, and some tender herbs for flavouring, as Basil &c., reserving the general sowing until March and April. Stirred the soil among young plants, and gave plenty of air to Cauliflowers, &c., to keep them hardy.

FRUIT GARDEN.

Gave a little water to Figs, so that the roots may be thoroughly moistened gradually; and the general work, outside and inside, the same as last week, taking every chance to syringe the walls with soapuds, with the addition of a little lime and a handful of salt to the score of gallons, which helps to keep the trees free of green moss and lichens. Potted-off a few Melon plants.

ORNAMENTAL DEPARTMENT.

Outside and inside much the same as last week. Brought a few small *Fuchsias* from a cool shed, where they can be forwarded in a little heat; will introduce some larger ones as soon as room can be found. At present the plants are dry rather than damp, but not dust-dry; syringed them overhead; will finish pruning, so that they shall break near home. When it is desirable to make large plants of last season's cuttings they should have a bottom heat of 70°, and a top heat of from 55° to 60°. The great work of the week, besides attending to necessary watering and cleanliness, has been potting-off Variegated *Geraniums* that were standing too thickly in boxes, examining the old plants which had been treated on the faggot system, putting in cuttings of new and fine kinds, and going right-ahead with *Verbena*-cuttings, putting them chiefly in half-circle-drain-tiles, with a thin piece of clay at each end, and setting them on a bed of leaves, with 2 or 3 inches of dry ashes over them, and the help of a water-pipe in front. At this season, with just a skiff from the syringe on a sunny day, they will need no shading. This is one of the best modes we have tried, except planting the cuttings out at once into beds, and for this we have no bed at present at liberty, and besides we would prefer doing it in the beginning of March, instead of the beginning of February. Those put in tiles now—say three plants to 10 inches—will afford cuttings by that time. Some may like to try the bed-system, and this is how we used to do it: Make-up a bed of leaves, or dung, or whatever can be had, that will raise a bottom heat of from 80° to 85°. Firm the surface, place on it a couple of inches of rotten dung or leaf mould; then riddle some rough sandy loam through a half-inch sieve. Keep the rough riddlings, mix that with an equal quantity of rough decayed leaf mould; make level, and then sieve 1½ or 2 inches more. Cover this with the fine soil—if not sandy, add enough to make it gritty and open—and make this also 2 inches in thickness; beat down with a quarter of an inch of sand thrown over, and gently pressed. Then stick in the cuttings with a bodkin-dibber, or, as Mrs. Bird does her *Calceolarias*, putting the cuttings 1 inch apart in the row, and 2 inches from row to row; water; keep close; give a little air at back at night, if only an eighth or a quarter of an inch; shade a little in bright sunshine, when a skiff from the syringe would not prevent the cuttings perspiring too much; give air by degrees as the roots are formed; and by May you will have fine strong plants with roots hanging in the leaf mould, and which may be taken to the beds, and scarcely feel the moving.—R. F.

TRADE CATALOGUES RECEIVED.

Smith & Simons, Glasgow.—*Cultural Guide and Descriptive Seed Catalogue.*

Robert Parker, Tooting, S.—*Catalogue of Agricultural, Flower, and Vegetable Seeds, Fruit Trees, New and Rare Plants, &c.*

W. Wood & Son, Maresfield, Uckfield.—*Catalogue of Seeds with an Appendix, comprising Roses, Fruit Trees, &c.*

Downie, Laird & Laing, 17 South Frederick Street, Edinburgh, and Stanstead Park, Forest Hill.—*Descriptive Catalogue of Florists' Flowers, and List of Vegetable and Flower Seeds, &c.* 1863.

Hooper & Co., Central Avenue, Covent Garden Market, London, W. C.—*Spring Catalogue of Flower, Shrub, Tree, and Kitchen Garden Seeds.*

A. Stansfield & Sons, Tadmorden.—*Catalogue of Stove, Greenhouse, Hardy Exotic, and British Ferns.*

Charles Turner's *Catalogue of Seeds for the Kitchen Garden, the Flower Garden, and the Farm.* Slough, 1863.

W. Thompson, Tavern Street, Ipswich.—*Descriptive Catalogue of Flower Seeds, 1863.*

F. & A. Dickson & Sons, Unto Nurseries, and 106, Eastgate Street, Chester.—*Catalogue of Vegetable, and Flower Seeds, &c.* 1863.

TO CORRESPONDENTS.

BLIGHT (H. G. M.).—It is no fungus which has attacked your Orange trees, &c., but the common aphides or green fly. Foregathered and springing will destroy them. They will be kept away by more moisture and a freer admission of air. Some injury to the roots of your cyclamens causes the abortive flowers.

BOATSWAIN (T. C. B.).—Filtering the suds through earth may be effected either by ascent or descent, as fully explained in the pamphlet published at our office, entitled "Muck for the Many." Some of the fertilizing parts of the suds would be detained by the earth. We use sossups unfiltered as a manure. You may have the Journal direct from our office, free by post, by prepaying 12s. 6d. per copy, or 5s. 6d. for six months.

ROSE CUTTINGS (G. R., St. Ives).—The only practical direction that can be given about cuttings of the old wood of the previous season is, that it will not come from cuttings "now in the open air in spring out of doors." But there is an easy way of rooting now all the young wood of all the prunings of all kinds of Roses, and that is to graft on six-inch lengths of Rose-shoots; and the roots of any sort of Rose are just as good for this mode of propagation as the roots of Dog or Manetti Stocks, as the graft must be planted so deep as to bury the grafted parts just 2 inches below the surface, so as to have the top but of the graft just within the soil and no full an inch. Then roots come from the grafts themselves before the summer is over, and the rootstocks may then be cut off for fear of making suckers. All this grafting can be done at home by the fireside, and such grafts if put into a box or basket in damp sand, will keep three weeks without being planted until the weather be bad. During this time the growth of last summer will thus graft if ripe and falling in the very bottom of the graft, an eye within half an inch of the top of the graft, and one or more eyes between the two. So there is no reason to waste an inch of the Rose-shoots. If the Rose, if it is pruned from the middle of February to the middle of April.

WHICH WOOD IS MOST VALUABLE? (J. T. P.).—This is a question which cannot be answered without knowing the locality where it is to be grown, and the purposes for which it is required. In some places the wood of the Poplar would be as valuable as that of the Oak. Your question reminds us of the following extract from the *Journal of Horticulture* for the summer of 1775, and entitled "Legend of the Tree of Life":—"Trees and woods have twice saved the world—first by the ark, then by the cross; making for sinners the evil fruit of the tree of Paradise, by that which was borne on the tree in Gogoltha."

SPRING CUTTINGS OF VARIEGATED GERANIUMS (Country Curate).—You are wrong on two very essential points. You water the spring cuttings of the whitest and more soft kinds of Variegated Geraniums "every three or four days according to the weather;" but one watering in three weeks in February and March is often all they can bear in a moist propagating-bed. We have struck those you name by the hundred without ever giving the soil in the pots a drop of water, but only a little damping with the syringe in the afternoons of very sunny days in March. The next error is setting the cuttings-pots for a week or ten days on a shelf in a moist propagating-house, "where, by the way, they would rot without watering later in the spring. Try them thus!—Cut very close below the joint after breakfast, and put the cuttings in a dry place till the afternoon for the cut ends to dry a bit; then push them in, and plunge them in bottom heat from 70° to 80° the same evening, so that the drop of water the first week, and only to the leaves afterwards; but the outside of the pots must be moist all the time from the dampness of the bed.

BEST PLANTS FOR EXHIBITION (A Young Exhibitor).—You are six months too late now, and you will not win a prize this season. All the "best kinds" are now three-parts grown and settled in the summer. Look to the lists of prize-taking plants at the last year's exhibitions.

DESTROYING WEEDS ON WALKS (Jardinier).—We certainly think there are many things more likely to be destructive to weeds than a mixture of lime and sulphur boiled together. This might, perhaps, be recommendable in giving colour to the pavement walks you speak of; but a sprinkling of salt or a strong solution of it would be more destructive, and there are many other substances as well as salt for this purpose. We have known a cheap preparation of arsenic very effective, and one in which copperas was used also good, but the last-named article left a stain behind it. For safety, simplicity, and cheapness salt is the best of all. The only fault it has is that it causes the walk to have a damp appearance at times. Small quantities often repeated after the first dose generally keep all vegetation down; and never prevent the walk as is likely to penetrate to the roots of trees below the walk's surface.

RIDDELL'S BOILER (G.).—Unless great care is exercised, all fires and moves inside of houses are apt to produce dust and a little smoke at times. In your circumstances, if it could be done easily, we would keep the boiler inside, but so placed as to have the feeding-door outside. Whatever may be stated in advertisements we have no faith in. The boiler or furnace heated by fuel or gas that has not a pipe to carry off the smoke and other products of combustion.

GERANIUM TULIFIFERA (Ignoramus).—This is the *Hedera tulipifera*. The culture of it is very easy, being the same in every respect as that of *Epacris* and all the other round.

CENTAUREA CANDIDISSIMA (C. W.).—*Centaura candidissima* is the best ribbon-border white-leaved plant yet known, and it has no other equals in the plant lists. No seeds of it have been offered yet for sale as far as we can learn.

CONTINERS (F. B.).—You mistake the question. All the hardy Conifers would feather down to the ground with their branches if they were treated for that way of growth as the soft-wooded plants are. D. B.

FURNACE FOR GREENHOUSES.—I have built a furnace as recommended by "J. S." in your issue of November 11th, but find that the fire does not heat well in thick muggy weather. "J. S." will, therefore, oblige if he will state what sized fire should be used, as it is just possible mine may be too large, being 12 inches by 12. My house is 17 feet by 12, and the fire is 16 inches by 12 inches square. Should the fire always be lighted at the top? J. B.

MELON SEEDS (J. Dunn).—Thanks for the Melon seeds. We shall have them sown in the original form.

PROPAGATING PINELAE SPECTABILIS (F. F.).—If there are a few short stubby shoots on your plant, from 2 to 3 inches long, you may slip them off as cuttings now; if not, wait until the plant has few degrees higher than it back, and when started afresh, from being a few degrees higher than it back, in a closer atmosphere, you may then cut the young shoots. When about 24 inches long take off close to the old wood, trim the bottom half, and insert in silver sand over sandy peat, and cover with a bell-glass, and the cuttings may be placed where they will have an advance of 5° or so for a fortnight, and then be plunged in a mild bottom heat of from 70° to 80°. Put them first in sandy peat, and as the plants grow larger and shifts are required, add a little dry loam.

MRS. POLLOCK GERANIUM BECOME GREEN (T. D.).—The dull winter and rich feeding would have a tendency to produce the result complained about; but we know so little of the means of bringing back the variegated form, but we could advise you to do nothing but to cut the plants pretty well down, and keep the roots rather dry. They break afresh. This we have sometimes found effectual, but not always. The great secret in the management of these variegated Geraniums. When we plant them out in poor soil we are more apt to keep the variegated form; but then the leaves come, being 12 inches by 12. My house is 17 feet by 12, and the fire is 16 inches by 12 inches square. Should the fire always be lighted at the top? J. B.

WOODEN FENCING (A. T.).—For a wooden fence 6 feet 6 inches high in the mountains of Lancashire, and to be covered with climbers, tarring the fence would be better than painting; or, if you paint it, the stone-coloured anti-corrosion paint is that we would use ourselves in that region of clouds and rain. Use some good strong iron wire, strain up 6 feet only, but some good common hardy shrubs, with here and there running Rose, a Jasmine and Honeysuckle, or a Clematis, but not nearer than 15 feet apart, Laurustinus, Berberis, Spiraea, or what are known already to grow well and answer in that part of the country.

FLOWER-GARDEN ELIAS (Suburban, Aberdeen).—Were it not that you had sent for our advice we should have thought Sir Joseph Paxton had made your flower-garden plan. It is a perfect beauty. To plant Roses or any plant higher than 18 inches in the sunk oval, in the centre of the garden, would defeat the aim of sunk plants. Raise them up as it were to the original level, or higher still by the height of the plants placed in the sunk parts. All your best and lowest of the bedders must be planted in that sunk oval, and not Roses. The two 7-beds, the two 16-beds, and the two 10-beds are your beds for Roses; the two 5-beds and two 19-beds for pillar Roses, and the two 19-beds ought to have some permanent evergreen; but this garden would look exceedingly well if only the two No. 7 beds were in Roses.

PLANTING ROSES (Anxious Inquirer).—The calendar says truly, the sooner Roses are planted, at the end of January, the better, although "that does not exactly fit your case." The how much later Roses can be planted with "safety" is this: They can be planted to the very middle of May and be as safe from dying outright as if they were planted at the end of October; but then they will do you little credit for the first two or three years. But the worst part of the story for a young gardener is the "you must order the plants to be sent to you as soon as you can ascertain how many will be wanted"—that is, perhaps you will be able to order the Roses at the end of February—just two months after the best plants, the second best plants, and the third best of all the best Roses, except the best old kinds, have been picked over and over again by the gardeners who do their work at the proper time. When you are "all right" tell us the kinds and the distances you mean to plant them, and we shall give our opinion on the merits of your plan.

GARDENER'S ADVERTISEMENT (R.).—Half-a-crown for each insertion. Moving Machine (Single-handed).—As you intend to impel it yourself, buy the machine, for that will be certain to require the least power, if kept oiled and free from rust.

CAMELLIAS (J. B. D.).—A basket has been received, the carriage of which was not paid.

WILD FLOWERS OF GREAT BRITAIN (T. Bell).—The work will contain all the flowering plants. We have not a prospectus left, but you will find it printed on the cover of each monthly Number.

ERYTHRAEA (Erythraea).—We have published the treatment of these plants often, and in the autumn and winter we would prefer those plants now that have fewest leaves on them. If the shoots of the head are large we would prune them back, and when the shoots were 14 inches long we would shake the most of the soil from the roots, and replot in strong rich loam, packed as firmly as the hands would permit; water, and keep shaded for a week, and as they grow give manure. If the wood was ripened last autumn, then every strong shoot thus made will produce abundance of flowers. If the head of the plant is small, then merely by pinching the young plants may be enough of pruning. If the plants are kept in-doors use the syringe freely, or you will have red spider.

NUMBER OF FLOW AND RETURN PIPES (A. F. B.).—One flow and one return pipe in connection with your saddle boiler will be sufficient, whatever the number of houses to heat left and right; but, according to the number of houses, you must have socket-pipes or T-junctions. The highest placed of these will generally heat the most powerfully, and regularity of valves will therefore be necessary. In such a case, the simplest plan would be to take the flow-pipe into an open cistern, some 2 feet above the highest pipe in the houses, and from that cistern take a flow-pipe to each part to be heated, to be controlled by plug or valve. All the return pipes must join the main return before it enters the boiler. We do not quite understand whether the boiler will not heat the several houses, or whether you merely wish some to be heated at one time and the rest at another time. The above is the simplest; if there is no cistern, then the different flows must be regulated by valves.

GAS LIME (A Three-years Subscriber).—The more clayey the soil the more gas lime you may put upon the soil to destroy the vermin in it. Two inches depth of the gas lime, thoroughly mixed with the soil, will not be too much. You must not plant anything on soil so treated until at least a week has elapsed.

FRUITS FOR AN EAST WALL (A Subscriber).—You will find the Royal Apricot do well on an east wall. You may also have Marie Louise, Winter Nelis, and Beurré Rance Pears; and Purple Gage, Green Gage, and Jefferson Plums.

CISUS DISCOLOR (A Subscriber).—It is one of the very easiest plants to grow of all stove plants. Give it a little of stove, and the consequence is a Puchsia, or Geranium, or Chrysanthemum, and the difficulty would be to know how to prevent it doing better than any other stove plant; and as to rooting cuttings of it, none root more easily. Your plants are No. 1, Begonia hyacinthifolia; 2, Echinanthus pulcher.

CALADIUM STARTING (Idem).—The question of starting Caladiums is like the question of starting Grape Vines, only a matter of convenience and cost. You may start Caladiums any day from the first of the new year, they will start of their own accord at the end of the spring. The starting of cuttings, and the sowing of all flower seeds in the spring, are just on the same principle as the starting of Caladium "roots." We saw many thousands of seedling Lobelia speciosa just sprout the first week of last January, and Lobelia speciosa will be in quite time enough for ordinary work if it is up by the 30th of March. Just so with Caladiums. When you can give them 75° of bottom heat, and you are sure they will have sufficient room, and from 56° to 75° of close moist heat, without check or hindrance, you may start. But first examine every root, and see, if there be a speck of decay on it; that is looked to before potting; give very small pots to begin with, and no water at all. Amateurs destroy their Caladiums, Cape bulbs, and Gladioli by acting as if it is a "root," which will keep for months in a dry state, they must have water the moment it is put into a pot. We never water a "root," even a water "root," until the leaf is well up above the pot, it is for were for three months after potting. But the soil potting time should be moist, and be kept so, in the dark and with some covering, till the leaf comes.

PROPAGATING SKEIN RHODODENDRONS (A Subscriber since 1856).—Grafting will suit your purpose best. Next month place the stocks of ponticum into a pit or frame; if there is just a little bottom heat all the better. When you start the stock over, and no water at all, the side, split two or three buds on the sort desired; tie, keep the place close and with a moist atmosphere. Sometimes, when you merely tie on a bud or two, it is desirable merely to nip-out the point of the stock, and only cut-back when the bud is growing. When you cut-back on a piece of shoot with its point, you must prefer cutting the stock over.

WIREWORMS (Idem).—A little ammoniacal water from the gasworks, or a bucket of fat scattered thinly, will cause the wireworms to decamp. For catching them, nothing is better than slices of carrots inserted in the soil and every morning.

NAMES OF PLANTS (A Reader).—1, Adiantum canescens; 2, Asplenium flabellifolium; 3, Some young Diplazium; 4, Miserable Pteris hastata; 5, Selaginella denticulata; 6, Taronia pinnatifida; 7, Aloe variegata; 8, Asplenium trichomanes; 9, Pteris tremula; 10, Isolepis gracilis; 11, a leaf we do not recognise. No one should send more than half a dozen specimens at a time. (F. G.).—1, Nerium Oleander; 2, Rhododendron dauricum atrovirens. You must send the others in flower. (F. S.).—Benthania fragrans. (A Appleton).—Your plant is Hexacentris myrsocina. Each volume you require, and which we can supply, will cost you 8s. 6d. (A 30-year Subscriber).—Your morcel from a window plant in Suffolk is the smallest-leaved kind of all the Horehounds, and is called Marubium pseudo-dictamnus. It is too too slender for the flower garden.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

POULTRY FOR THE LONDON MARKET.

POULTRY may come to London from all parts. A poultry show would be impossible without railways; and that which makes a show possible makes it easy to send surplus poultry to London. Peas and asparagus come from Algiers and France; new potatoes from Cornwall. They not only find a sale—they are looked for. It is just possible they were not at first. Of the early ventures, some were failures, perhaps, but senders were not discouraged, and they are now known, and they know their trade. Those who provide early delicacies are seldom among the rich. The seasons do not yield without a struggle; heat must fight against frost, and a dry and even temperature must promote and equalise growth. In chickens, little attentions by candlelight must shorten nights, and well-chosen and varied food must provide the internal heat that will radiate and form its own atmosphere. Such attentions are troubles, and are seldom undertaken by those who are well off. Neverthe-

less, a clergyman, his wife or daughter, has often contributed material help to a club or a poor family. Or one of those humble invaluable—the single lady of the village, the sister of a former vicar, the widow of the popular surgeon who was cut off by fever while attending the poor, or the unmarried daughter of the lawyer who died some time before—these blessed visitors often get a little help from poultry (none know so well as these, that empty-handed sympathy is poor work). These will rear their chickens and think they are well paid for their trouble, when the few shillings alleviate some poor person's pressing want, or help them out of trouble.

Poultry-keeping by cottagers in England is out of the question. They have not space, and the abominable system of field work for women renders it impossible. While in Germany, prices, and in France, gentlemen, make it a calling, it seems *infra dig.* in England. More fowls are kept than were kept a century ago, yet fewer come to market. There are sometimes apasmotic attempts in certain districts, but they die out. The small farmer and the small landowner disappear. The stream overtakes them, and swallows them up. With them goes the poultry. South-downs, Short-horns, and Berkshires take its place.

Fashion has done, one thing;—it has made it correct to breed poultry, and to exhibit it. Every one is anxious to sell it alive; but regular fattening is not to be thought of. Why should it be? By a strange perversion, you may take a delicately-brought-up lady who has been the ornament of a town circle, move her into the country and she will undertake poultry or anything of the kind, while her counterpart reared and living in the country will not look at anything of the sort. When we have sought for the cause, we have been told "it does not pay." We differ. All want the highest price; but all do not provide the best quality. Large prices only belong to those who send their goods at the most propitious time. In poultry, that means in the early season. The real demand for expensive poultry is from the latter end of April to the beginning of July. The chickens must be chickens of the year, and must not weigh less than 2½ or 3 lbs. each. They must be moderately fat, well killed and pickled, and fasted. There will always sell at remunerating prices—from 7s. to 9s. the couple—often more. It is, however, useless to undertake this unless with a determination to succeed. Little chickens in June are spring chickens, and may be rare in the country they come from, but they are unsaleable in London because it is their natural season, and there is a glut of them. Very often the chickens that are sacrificed in May by being killed before they have attained proper growth would, if they were allowed to live till June, make a large price. We call the attention of those of our readers who have inclination and leisure to the subject, and we shall always be glad to give instruction or answer queries.

NANTWICH POULTRY EXHIBITION.

FEBRUARY 6TH AND 7TH.

SPANISH.—First and Second, W. Woolley, Banbury. Third, J. B. Bruce, Keele. Highly Commended, J. Groot, Haughlin. Highly Commended, J. Gibson, Over. **CHICKENS.**—First, W. Woolley. Second, J. Hulse, Winsford. Third, J. A. Sheen, Tilsdon. Highly Commended, J. B. Bruce.

DUCKS (Any variety).—Plate Prize, A. Heath, Winsford. Second, J. Groot, Haughton. Third, H. Akroyd, Dodington. Ducks (Rinn, Fries, J. B. Bruce, Keele. Second, R. Cooke, Jan., Darnhall. Third, T. Burgess, Burleydam.

DUCKS (Any other variety).—First, R. Cooke, jun., Darnhall. Second and Third, E. Bowers, Broad Lane.

GESE.—First, W. Fennell, Norton. Second, J. Sheen, Tilsdon. Highly Commended, T. Walker, Betley. Commended, E. Bowers, Broad Lane.

TURKEYS.—First, Mrs. Akroyd, Dodington Hall. Second, W. H. Horaby, Shrewsbury Hall.

DORLINS (White).—First, Mrs. Tollemache, Dorfold Hall. Second, E. Cooke, jun., Darnhall.

DORKINGS (Any other colour).—First and Plated Tespot, Mrs. E. D. Broughton, Wistaston. Second and Third, E. Tudman, Highchurch. **CHICKENS.**—First and Second, E. Tudman. Third, Mrs. Tollemache, Dorfold Hall. Commended, Mrs. Tollemache; T. Burgess, Burleydam.

COCHIN-CHINA (Cinnamon, Buff, and Partridge).—First, Second, and Silver Cup for best pen in the Exhibition of any kind of poultry, E. Tudman, Highchurch. Commended, T. Rigby. **CHICKENS.**—First and Second, E. Tudman.

COCHIN-CHINA (Any other colour).—First, J. Dodd, Minshall Vernon. Second, G. Williamson, Nantwich. **CHICKENS.**—First and Second, J. Dodd.

A Silver Cup, presented by the Licensed Victuallers of Nantwich and neighbourhood, for the best Game Cooker of any colour, exhibited specially for this prize. Victuallers' Cup, W. Galley, Nantwich. Second, E. D. Broughton, Wistaston. Third, E. Ashley, West End. Fourth, T. Burgess, Burleydam. Highly Commended, J. Platt, Darnhall; T. Burgess; J. Heath, Nantwich; Commended, T. Burgess; J. Heath.

GAME COCKS (Sweepstakes).—Prize, T. Burgess, Burleydam.

SINGLE COCKS.

GAME (Black-breasted Reds).—First, J. Wilkinson, Norbury. Second, T. Moore, Nantwich. Third, J. Heath, Nantwich.

GAME (Brown-breasted Reds).—First, T. Whittingham, Batherton. Second, J. Pedley, Nantwich. Third, J. Heath, Nantwich. Highly Commended, T. Burgess, Burleydam. Commended, T. Burgess; R. Ashley, West End; J. Heath; E. Bowers, Broad Lane.

GAME (Any other colour).—First, T. Burgess, Burleydam (Black). Second, A. Heath, Winsford. Third, Miss Sadler, Heath Cottage, Whitchurch. Commended, T. Burgess (Black).

GAME (Black Reds).—First, J. Grocott, Haughton. Second, J. Pedley, Nantwich. Third, J. Heath, Nantwich. Highly Commended, J. Heath. Commended, T. Moore, Nantwich; A. Heath, Winsford. *Chickens*.—First, W. Ruscoe, Nantwich. Second, T. Burgess, Burleydam. Third, T. Whittingham, Batherton. Commended, T. Burgess; J. Grocott.

GAME (Brown Reds).—First and Plate, E. Bowers, Broad Lane. Second, S. Edwards, Nantwich. Third, Dr. E. Bellyse. Highly Commended, T. Burgess, Burleydam; J. Heath, Nantwich. Commended, J. Pedley, Nantwich. *Chickens*.—First, W. Galley, Nantwich. Second and Third, T. Burgess. Commended, R. Latham, Woore; J. Grocott; J. Heath; H. Holland, Nantwich.

GAME (Any other than Black or Brown Reds).—First, Miss Sadler, Heath Cottage, Whitchurch (Grey). Second, T. Burgess, Burleydam (Black). *Chickens*.—Prize, Master E. W. D. Broughton, Wistaston (White).

GAME HENS (Any colour).—First, A. Mountford, Keele (Brown Reds) Second, W. Hope, Newtown (Brown Red). Highly Commended, T. Burgess, Burleydam (Black-breasted Red). Commended, T. Whittingham, Batherton (Black Red).

HAMBURGH (Golden-pencilled).—First, W. H. Hornby, M.P. Second and Third, G. Williamson, Nantwich.

HAMBURGH (Silver-pencilled).—First and Second, D. Harding, Middlewich. Third, Rev. A. Silver, Norton.

HAMBURGH (Golden-spangled).—First and Hamburgh Silver Cup, T. Burgess, Burleydam. Second, R. Foster, Marsh Lane. Third, J. Dutton, Bunbury.

HAMBURGH (Silver-spangled).—First and Third, T. Dale, Middlewich. Second, J. B. Bruce, Keele. Commended, T. Dale; R. Foster, Marsh Lane.

POLANDS (Any variety).—First and Second, J. Heath, Nantwich. Third, G. Williamson, Nantwich. *Chickens*.—First and Second, G. Williamson, Nantwich. Third, Mrs. Sproston, Middlewich.

BANTAMS (Game).—First, W. Griffiths, Nantwich. Second, J. G. Pearson, Whitchurch. Third, J. Grocott, Haughton.

BANTAMS (Any other variety).—First, T. Butler, Middlewich (White). Second, S. Boffey, Willaston (Spangled). Third, withheld.

GAME BANTAM COCKS.—Plate, W. Griffiths, Nantwich. First, T. Stanyer, Nantwich. Second, J. G. Pearson, Whitchurch.

PIGEONS.—*Carriers*.—First and Second, W. Woolley, Dunbury (Black and Dun). Very Highly Commended, J. Hockenhuil, Nantwich. *Dragons*.—First, D. Harding, Middlewich (Blue). Second, F. Davies, Eardswick (Black). Highly Commended, J. Hockenhuil. *Pouters*.—First and Second, W. Woolley (Red and Blue). Highly Commended, W. Crawford, Nantwich. *Barbs*.—First and Second, J. Hockenhuil. Very Highly Commended, W. Crawford. *Nuns*.—First, J. Dutton, Bunbury. Second, J. Hockenhuil. Highly Commended, T. Horton, Leighton. *Beards*.—First, S. Cawley, Priestland (Blue). Second, J. Hockenhuil (Blue). Commended, J. Hockenhuil. *Balds*.—First, J. Withinsaw, jun., Nantwich (Black). Second, T. B. Davies, Eardswick (Black). Highly Commended, T. B. Davies (Black). *Any other variety of Tumblers*.—First, F. Cawley (Red Mottles). Second, W. Crawford. Commended, H. Prince. *Fantails*.—First, H. Prince (Black). Second, C. B. Davies. Very Highly Commended, Miss A. Tollemache (Blue). Commended, J. Hockenhuil (Black and White); Miss A. Tollemache (Black). *Jacobins*.—First, J. Hockenhuil (Yellow). Second, C. B. Davies (Black Balde). Commended, J. Hockenhuil (Red). Highly Commended, T. B. Davies (Black). *Trumpeters*.—First, T. Horton (Black). Second, F. Davies (White). Highly Commended, T. Horton (Black Mottles). *Owls*.—First, J. Hulse, Winsford. Second, W. Betley, Nantwich. *Turbits*.—First, S. Newbrook, Nantwich (Red). Second, J. Withinsaw, jun. (Blue). Highly Commended, J. Withinsaw, jun. (Blue). Commended, J. Dutton (Blue). *Any other variety*.—First, J. Dutton (Labores). Second, J. Hockenhuil (Archangels). Highly Commended, J. Dutton (Magpies). *Doves*.—First, J. Cooper, Nantwich (White). Second, J. Hockenhuil (Ring). Commended, J. Hockenhuil (King and White); G. Green (Ring).

SINGING BIRDS.—*Canaries* (Yellow).—First, H. Sumner, Nantwich. Second, S. Williamson, Nantwich. Highly Commended, R. Wood, Nantwich. Commended, H. Sumner. (Buff).—First and Second, H. Sumner. Highly Commended, R. Wood. (Any other variety).—First, C. Indley, Crewe. Second, S. Williamson, Nantwich. Commended, S. Williamson. *Brown Linnets*.—First, T. Moulton. Second, R. Williamson, Nantwich. Highly Commended, H. Timmis, Walgherton. Commended, W. Basford. *Goldfinches or Red Linnets*.—First, H. Sumner. Second, R. Williamson, Nantwich. Highly Commended, H. Sumner. Commended, D. Robinson, Nantwich. *Skylarks*.—First, J. Willett, Nantwich. Second, T. Williamson, Nantwich. Highly Commended, J. Willett; T. Williamson. *Bullfinches*.—First, W. Williamson. Second, D. Robinson. Highly Commended, J. Willett, Nantwich; W. Williamson. *Woodlarks* (not for competition).—Prize, S. Williamson, Nantwich.

RABBITS.—*For Long Ears*.—First, W. J. Sheen, Tilston. Second, C. Lees, Sandbach. *For Weight*.—First, E. Woolley, Bunbury. Second, S. Bullock, Nantwich.

APOPLEXY IN FOWLS.

A. B. would feel obliged if any light could be thrown on the complaint of which her Dorking fowls died. One, a fine hen she lost a few months since, did nothing but sleep for about ten days, did not appear to suffer, and its comb retained its beautiful colour. It ate when food was offered. Medicine did no good, and it died, bringing-up at the last a quantity of coagulated blood. A Dorking cock lately was similarly affected; but in his case his head was continually going round. Medicine and bleeding in the foot were tried, but without effect, and at

last he was put out of his misery. Was it apoplexy? The cock's comb turned black; not the hen's. There was no over-feeding.

[There is no doubt that the fowls died from apoplexy, and if their heads had been opened a clot of blood would have been found on some portion of the brain. If our correspondent knows, from having the body opened, that the birds were not fat, the usual cause of such attacks, then either great frights or other excessive excitement was the probable cause. If no such cause can be discovered, then we fear there must be an hereditary tendency to an excessive flow of blood to the head.]

CRYSTAL PALACE BIRD SHOW.

AMONG the many exhibitions of the country there is not one more interesting than that of Canaries and British and Foreign Birds at the Crystal Palace. We have now the pleasure of discussing the merits of the fifth annual Show. It is again our most pleasant duty to congratulate the management upon the great success of the undertaking from its commencement.

It has now successfully passed the trying ordeal of five seasons, and we venture to state that for the future it may be looked upon as an established annual Exhibition, and as taking first class with its contemporaries. We were pleased to notice the considerable preponderance of the fair sex in the number of visitors on Saturday. It shows that they are much interested in the welfare of Nature's smallest pets. We do not know an exhibition of zoology more suited to the tastes of ladies than this, and we are glad to notice that there are a great many lady competitors on the list. One might almost fancy that it is the middle of summer instead of winter, in such a delightful place as the tropical department of the Crystal Palace, with its beautiful and luxuriant plants, and the sweet notes of the little feathered prisoners, which seem to endeavour to surpass each other in sending forth their carols.

The collection is on the whole an extremely fine one; and it is evident that the admirers of this class of ornithology, both dealers and amateurs, have not failed to exert themselves to bring the specimens to perfection.

The Judges, we fear, must have had a very difficult and not altogether an agreeable task to perform in awarding the prizes to so many birds, the defects of which none but those who have made them a study can detect, as a feather missing here or a toe there can alone sometimes decide which is deserving the honour of a prize.

We could not, were we compelled to do so, commend any one class specially; it is almost next to an impossibility. However, we will notice one or two of the most interesting specimens. The British birds form quite a collection of themselves, and are in beautiful condition and splendid plumage. Among the curious specimens were a white Thrush exhibited by Mr. E. Hawkins, and a spotted Blackbird, the former of which, although tailless, was awarded a prize. We observed also some very curious varieties, consisting of a Goldfinch, a Grey Linnet, a Robin, and a common Sparrow, of which the two first mentioned obtained a prize. A singular and rare hybrid between a Norwich Canary and a Citril Finch from the Cape was shown, and also two beautiful Mules between a Goldfinch and Bullfinch, which were much admired, and one of which took a prize. There was also a Swallow reared from the nest, which is a very curious and unusual occurrence. Among the Foreign birds were some very beautiful and finely-coloured specimens. One of the most interesting subjects was a pair of Budgrigars, with nest, and eggs, and young.

The show of Canaries far surpassed any previous collection, both in numbers and quality. The specimens were magnificent in the extreme. The Norwich, the Belgians, London Fancy, and Lizards were most beautiful, and especially the Mule birds, in praise of which we cannot speak in sufficiently high terms.

Too much praise cannot be given to the Secretary, Mr. Houghton, for his exertions in promoting the interests of the undertaking.

CANARIES.

NORWICH, Clear Yellow.—First, T. Banfather. Second and Third, R. Mackley. Equal Third, J. Pullen. Very Highly Commended, — Collinson; R. Mackley. Highly Commended, S. Dunthorne; E. Hawkins; W. Laws; J. Pullen; Mrs. Lowth; R. Mackley. Commended, E. Hawkins; W. Walter; — Collinson. (The whole of the class very superior.)

NORWICH, Clear Buff.—First, E. Willis. Second, W. Walter. Very Highly Commended, J. Pullen; W. Walter; F. Willis. Highly Commended, R. Mackley. Commended, J. Pullen; R. Mackley. (A good class.) NORWICH, Variegated or Marked.—First, J. Judd. Second, W. Walter.

Very Highly Commended, W. Walter, R. Mackley. Highly Commended, E. Hawkins; J. Morse; Commended, J. Judd. (A good class.)
 NORWICH, Crested or any other variety.—First, R. Mackley. Second, J. Judd. Very Highly Commended, R. Mackley. Highly Commended, R. Mackley.

BELGIAN, Clear Yellow.—First and Third, E. Hawkins. Second, J. Webb. Very Highly Commended, E. Bemrose; J. Lingard; O. Nicholson; W. Triggs. Highly Commended, S. H. Goodwin; H. Marshall (Good bird, but two toes defective.) (A very superior class.)

BELGIAN, Clear Buff.—First, H. Marshall. Second, G. Harding. Very Highly Commended, E. Bemrose; O. Nicholson; W. Phillips; J. Webb. Highly Commended, E. Hawkins; H. Marshall. Commended, C. Stockdale.

BELGIAN, Variegated, or Marked Yellow.—First, H. Marshall. Second, E. Hawkins. Third, E. Bemrose. Very Highly Commended, S. H. Goodwin; O. Nicholson; E. Hawkins.

BELGIAN, Variegated or Marked Buff.—First, E. Hawkins. Second, E. Bemrose. Very Highly Commended, E. Hawkins; J. Judd. Commended, S. H. Goodwin; J. T. Wilson.

BELGIAN, Crested or any other variety.—First, J. James. Second, G. Harding. Very Highly Commended, E. Hawkins. Commended, W. Walker.

JONQUE LONDON FANCY.—First, J. Waller. Second and Third, O. Green. Very Highly Commended, J. Waller. Highly Commended, O. Green.

MEALY LONDON FANCY.—First and Second, J. Waller. Very Highly Commended, O. Green. Highly Commended, O. Green.

CANARIES, German or any other variety, except Norwich or Belgian.—First and Second, J. Judd. Highly Commended, J. Judd. Commended, J. Judd.

LIZARD, Golden-spangled.—First and Second, E. Hawkins. Third, J. Waller. Very Highly Commended, S. H. Goodwin; E. Hawkins; J. Lingard; J. Waller. Highly Commended, E. Hawkins; F. W. Fairbrass; J. Lingard. Commended, H. Marshall. (Remarkably good.)

LIZARD, Silver-spangled.—First, W. Smith. Second, J. Lingard. Third, E. Hawkins. Very Highly Commended, F. W. Fairbrass. Highly Commended, E. Hawkins; J. Webb. (Class very good.)

GOLDFINCH MULE, Jonque.—First, W. H. Morgan. Second, G. Barnesby. Third, H. Marshall. Very Highly Commended, G. J. Barnesby; W. Walter. Highly Commended, C. C. Stockdale. (Most admirable.)

GOLDFINCH MULE, Mealy.—First, F. Hook. Second, C. C. Stockdale. Third, Mrs. La Touche. Very Highly Commended, E. Hawkins; T. Brown; J. Judd. Highly Commended, S. H. Goodwin. (A good class.)

CANARY MULE, any other variety.—First, H. Marshall. Second, Master C. H. Verner. Third, J. Judd. Very Highly Commended, J. Judd.

BRITISH BIRDS.

BULLFINCHES.—Prize, Miss La Touche. Very Highly Commended, E. Hawkins; P. Nicholson. Highly Commended, W. Walter; R. Mackley.

CHAFFINCH.—Prize, F. P. Cuddon. Highly Commended, F. Hook.

GOLDFINCH.—Prize, J. Crew. Very Highly Commended, J. Lingard; R. Mackley. Highly Commended, F. P. Cuddon; W. H. Woodcock.

LINNETS.—First, E. Hawkins. Equal First, J. Judd. Very Highly Commended, H. Hanley. Highly Commended, H. V. Reid; E. de la S. Simmonds.

SKYLARKS.—Prize, W. Walter. Very Highly Commended, J. Judd. Highly Commended, J. Judd; R. Mackley.

WOODLARK.—Prize, W. Walter. Very Highly Commended, J. Judd.

ROBINS.—Prize, C. C. Stockdale. Very Highly Commended, J. Crew. Highly Commended, C. C. Stockdale; J. Waller.

BLACKBIRDS.—Prize, R. Simpson. Very Highly Commended, Mrs. Dodd.

SONG THRUSHES.—Prize, Mrs. Dodd. Very Highly Commended, Mrs. Dodd; G. Page; R. Mackley. Highly Commended, J. La Touche.

THRUSHES OF ANY OTHER VARIETY.—Prize, E. Hawkins.

STARLINGS.—Prize, T. Gerlach.

MAGPIES.—Prize, W. Walter.

JACEDAWS.—Prize, W. Walter.

ANY OTHER VARIETY OF BRITISH BIRDS.—Prize, E. Hawkins (White-breasted Goldfinch). Very Highly Commended, E. Hawkins (Black Bullfinch). Highly Commended, T. P. Cuddon; H. Hanly; J. Pullen.

HYBRID OR MULE BIRDS, Any variety except Canaries.—First and Third, H. Hanly. Second, C. C. Stockdale.

BIRDS OF PASSAGE AND MIGRATORY BIRDS.

BLACKCAPS.—Prize, W. Bicknell.

NIGHTINGALES.—Prize, C. C. Stockdale. Highly Commended, J. Crew.

SISKIN OR ABERDEVINE.—Prize, J. Judd. Very Highly Commended, G. J. Barnesby; T. Gerlach. Highly Commended, W. Bicknell; E. Hawkins; T. Gerlach.

TITLARKS OR TREE PIPITS.—Prize, E. Hawkins. Highly Commended, J. Judd.

ANY OTHER VARIETY.—Prize, W. Bicknell (Gill Bunting). Highly Commended, E. Hawkins (Redpole).

FOREIGN BIRDS.

COCKATOOS, Any variety.—First, Mrs. Emm. Second, J. Judd (Rose-breasted). Highly Commended, Capt. Payne (Rose Cockatoo).

GREY PARROTS.—First, Mrs. Statham. Second, E. Hawkins. Very Highly Commended, J. Decaisne; J. Rose; J. Lingard.

GREEN PARROTS, or any other large variety except Grey.—First, W. W. Westbrook. Second, C. W. Wass. Third, J. Rose.

LOVE BIRDS, in pairs.—Prize, E. Hawkins.

AUSTRALIAN GRASS PARAKEETS, in pairs.—Prize, W. Barnes. Very Highly Commended, E. Hawkins; J. Rose; J. Waller.

PARAKEETS, Ring-necked or Bengal.—Prize, E. Hawkins.

PARROTS OR PARAKEETS, any other small variety.—Prize, E. Hawkins.

PARAKEETS, Rose Hill.—Prize, Capt. W. R. Payne, R.N. Very Highly Commended, E. Hawkins. Highly Commended, J. Judd.

PARAKEETS, Pennant's.—Prize, E. Hawkins. Highly Commended, J. Judd.

PARAKEETS, Blood-wing.—Prize, E. Hawkins. Highly Commended, J. Waller.

PARAKEETS, Yellow-winged.—Prize, E. Hawkins.

PARAKEETS, Red-rump (in pairs).—Prize, J. Judd.

COCKATEALS, in pairs.—Prize, J. Judd. Highly Commended, E. Hawkins.

DIAMOND SPARROW, Single.—Prize, A. Johnson.

CORAL-NECKED SPARROWS, in pairs.—Prize, J. Judd. Very Highly Commended, E. Hawkins.

JAVA SPARROWS, in pairs.—Prize, E. Hawkins. Very Highly Commended, E. Hawkins. Highly Commended, Miss Solomon.

INDIGO BLUE BIRDS.—Prize, J. Judd.

ZEBRA WAX-BILLS, in pairs.—Prize, A. Johnson. Highly Commended, J. Judd.

WAX-BILLS, any other variety, in pairs.—Prize, A. Johnson. Very Highly Commended, E. Hawkins. Highly Commended, A. Johnson.

VIRGINIA NIGHTINGALES.—Prize, C. C. Stockdale.

CARDINALS.—Prize, W. Walter. Very Highly Commended, E. Hawkins.

WHITEN BIRDS.—Prize, E. Hawkins.

FIREFINCHES.—Prize, E. Hawkins. Highly Commended, J. Judd.

FOREIGN BIRDS, any other variety.—First, A. Johnson. Equal First, J. Armeson. Highly Commended, E. Hawkins.

THE BEST GROUP OF FOREIGN BIRDS IN ONE CAGE OR AVIARY.—Prize, E. Hawkins.

JUDGES.—Canaries: Mr. T. Moore, Mr. A. Willmore.

British and Foreign Birds: Mr. W. Goodwin.

ON THE FIRST FLIGHT OF BEES IN SPRING.

[From the German of ADALBERT BRAUN.]

BY "A DEVONSHIRE BEE-KEEPER."

Hark! what is so gaily humming

In the little garden there?

Hark! what is so briskly whizzing

Through the still and silent air?

Friend, it is our bees—the darlings—

Now enliven'd by the spring;

Yes, the winter is departed,

And once more they're on the wing.

Happy he, who winter's perils

All his stocks brings safely through;

Thank Him, of all good the Giver—

Faithful Watchman He, and true.

Of my own are none departed,

All as yet unhurt remain;

Though no longer rich in honey,

Yet is spring returned again!

Come, and let us view them nearer—

Enter by the garden gate;—

So—stand-still and watch their doings—

Light your pipe, and patient wait.

See how busily they traverse

To their pasturage and back,

That they may by toil unwearied

Save the commonwealth from wreck.

Look, O look, what loads of pollen,

Bring they in with heedful care.

Nurslings, fear not; for your cravings

Here's sufficient and to spare.

How they dart and how they hurtle

Through the genial balmy air!

To the mountains—to the meadows—

'Tis the scent attracts them there!

There they dexterously rifle

Nectar from each flow'r in bloom.

Toil they for our honey harvest,

For us fill the honey-room.

Yes, our bees, our darling darlings,

We salute you all to-day;

For your life is our enjoyment—

Winter's sleep has pass'd away,

Grant prosperity, O Heaven!

To the new-born honey-year—

Give thy favour—give thy blessing—

To these objects of our care.

Now let each attentive gardian

In devoted service strive

For the proud, the matron-monarch—

Sov'reign of the honey-hive.

So that we may learn by watching

Who that in the noon-tide glance,

Or in midnight's darkest moments,

Summon her to Hymen's dance.*

Ev'ry bee-hive calls for patience,

Whilst great HALLER's lessons teach

Without patience Nature's secrets

None successfully can reach.

—T. W. WOODBURY, Mount Radford, Exeter.

* This point cannot now be considered doubtful, but it must be remembered that Herr Braun's verses were written seventeen years ago.

PROFITLESS BEES.

My Journals of this week and last have greatly interested me—Mr. Lowe last week, Mr. Woodbury this; also "T.'s" experience is such a parallel with mine and that of hundreds of others, that additional remarks on these subjects must be greatly valued by all classes of apiarians.

Now, as to my former complaint of the gradual decrease of bees from their hives. From all I can gather this does arise from the want of fertility in the queen, either from age or otherwise. Now, it is a well-known fact that the kind of food taken by the female of all animals greatly influences her productive powers; this is seen conspicuously in the common fowl.

I have always administered to my bees in autumn a liberal supply of syrup made of loaf sugar and water. Think you this artificial food is in any way injurious to the queen's productive powers? Fearing this might be the case I have fed with honey, dearly purchased, this autumn; but I determined to have one more good trial.

As to their unprofitableness. It appears to me there are three requisites absolutely necessary to insure success—First, fertility in the queen; second, suitable pasturage; third, favourable weather. The absence of either of these, in whatever hive the bees may be located, will be sure to cause a failure; for although the queen may be very fertile, with good pasturage combined, yet if the weather be bad there will be no collection; neither if the weather be ever so fine and the queen very fertile, if there be no pasturage within reach there can be no collection; or if the pasturage be good, joined with good weather, yet if the queen be not fertile then there will be no collection. Of course it is out of the power of any apiarian to affect either pasturage or weather; but to keep a succession of fertile queens is, I certainly think, as possible to an intelligent bee-keeper as it is to a farmer to keep good stock of any of our domestic animals; but the way to do this is the difficulty. The recent remarks in the Journal of Dzierzon and "A DEVONSHIRE BEE-KEEPER," on this subject, have I think been conflicting; I, therefore, beg the particular attention of our intelligent correspondents to this one point, and their early remarks will oblige and gratify your readers.

Before I conclude my note let me remark as to pasturage. Very much must depend upon its distance from the apiary; and the question, so often put and never answered, constantly recurs, How far does the bee fly in search of honey? Many have remarked upon it, the indefatigable Huber, Huish, and others, but their observations do not agree. I sincerely hope if any of your correspondents have any facts on this subject they will give them to the world through your Journal. For these two questions—First, How to secure a fertile queen; second, the probable distance of the flight of the bees—concern every bee-keeper on the face of the earth; for the latter will inform us if our situation is suitable, and the former in that case will teach us how to insure success.—E. FAIRBROTHER, *Woolwich*.

[Feeding bees in autumn on sugar and water alone in no way affects the reproductive powers of the queen. We shall be glad of the opinions of our correspondents on the other questions mooted in the foregoing communication.]

"TRUTH" AND THE BOTTLE.

I AM so glad to find that Truth is still on the earth, for, from the legend reported about her a short time ago, I very much feared she had become entirely disgusted with mankind. The *Times* gave the history, but as I have not the original printed words by me, I will merely write my own impressions of them, in order to reveal my joy at learning that Truth is still bravely amongst us above ground.

Well, poor Truth feeling herself very cold and uncomfortable at the bottom of her well, resolved one fine day to resort for an airing amongst the green budding bushes, and enjoy the warblings of the robins and hedge sparrows, the warm banks where the violets and the primroses bloom; and went sauntering about the beautiful meadows, where the sunbeams and the young lambs played, which so invigorated and emboldened her, that she determined to try the villages and small country towns. Poor Truth fared but badly there, she was laughed at, flouted, and insulted, and found it such hard lines to exist amongst the grandest bipeds of Nature's workmanship, that she determined to return to her well again. When lo! sitting upon the brink of the subaqueous habitation, she encountered a fine lady dressed all in the extreme of the

fashion, who exclaimed, "Dear Truth, don't run away or feel alarmed, my name is Fiction. But, darling, wherever have you been? How could you think of going about in that state? There, now, cool your eyes and temples with some of this eau de cologne, and let us commune a little together. But, first, tell me what has happened?" "Well, I can go about freely enough," replied Fiction. "In fact, I have been, and gone, and rather overdone it, and feel quite blasé! Look here, darling, this is crinoline. There, come now, do not run away again, nor seem so frightened, for there is no fire here, and I have a great mind to discard it; and then the immense width of the skirts of my dress will make two nice garments for us, darling, and enable us both to go into society more comfortably."

At this consummation so devoutly to be wished, your distinguished neighbour and contemporary took up the other thread of his article, and left THE JOURNAL OF HORTICULTURE of the 3rd inst. to inform us, that Truth, as I must reasonably suppose, agreed to the compact, and remains on *terra firma*. When "TRUTH" comes this way I invite a call, for I have some very good home-made of last year's vintage, the discussion of a bottle of which I feel almost sure would cause an exclamation, "Truth is in the bottom of a bottle!"

As to the "Bottle Bee-feeder," I would not tap the tops of my hives to apply it at this time of year on any account. My practice is to retain the temperature, and the tops of the hives quite undisturbed at this early breeding season. Besides, the "bottle-feeder" has been so well pushed and recommended by far superior authorities in the matter than I can hope to become. I never said one wilful word in disparagement of the article, and I do not doubt its capabilities. I would use it after what has been said in its favour with pleasure and confidence; but I like to see my bees partaking of their autumn banquet when it is necessary to feed them.

"TRUTH'S" "zinc feeders of every description," as far as I am concerned, resolve themselves into one simple contrivance, by which I am now supplying my bees with food through the entrances of the hives, and they partake of it, I am happy to say, with infinite gusto.

Ah! I am sorry to inform your estimable "DEVONSHIRE BEE-KEEPER," that we have no flowers open here yet for early pollen-gathering; but my bees are every day out and abroad. They are in excellent health, and shine like French-polished mahogany.—UPWARDS AND ONWARDS.

EARLY POLLEN-GATHERING.—For the last few days the bees in this neighbourhood have been as active as they frequently are two months later in the season. As early as January 27th, I perceived pollen-gathering to be general, there being abundance of flowers, and especially crocuses, now in bloom here. This is earlier than in any season of my experience. I perceive that "A DEVONSHIRE BEE-KEEPER" has made similar observations, but Lincolnshire is at least a fortnight behind Devon in point of climate.—G. F. B., *Spalding*.

OUR LETTER BOX.

INCUBATOR (W. B. J.).—In our No. 321 is a drawing and notes on the management of an incubator. The temperature to be maintained is 104° or 105°. We know of no work now on the subject that can be had except occasionally at second-hand booksellers. Minessi and Cantello printed pamphlets relative to their incubators.

GAME BANTAM'S LEGS (Bantam).—A white-legged Bantam cock must not be shown with willow-legged hens. If they were the best birds in the world non-matching legs would disqualify them.

SORA'S POULTRY ESTABLISHMENT (W.).—We do not know the distance of Mr. De Sora's establishment from Paris. The system has never been tried in England. It has been successfully carried on in Germany by the Prince of Tours and Taxis.

SILVER-PENCILLED HAMBURGH'S FEATHERS (A. Walker).—The brown feathers in a Silver-pencilled Hamburg are not desirable for exhibition. They are generally found on birds that are excellent for stock; as they are proved to be associated with bright, dark, and sharp pencillings. This and the creamy tinge are disadvantages in competition, but not disqualifications.

WHITE CRESTS OF POLANDS (Constant Subscriber).—Much of the dirt of which you complain on your Poland's crests is the result of the long-continued wet, which has made every place muddy. The only plan to avoid this annoyance is to put an india-rubber band round them about half an inch from the head; but we think when the weather clears up you will have no cause to do so.

MULE CAGE BIRDS (J. W.).—We do not think that you will be successful in breeding mule birds by turning Goldfinches and Canaries into a spare room as you propose. We would recommend that they be kept in pairs in separate cages. The Goldfinch should be the male bird; and to make success more probable the Goldfinch should be brought up from the nest in company with Canaries, or be kept in a cage about twelve months, so as to be somewhat tame. They should be treated in the same manner as Canaries when breeding.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 45.8° and 32.5° respectively. The greatest heat, 58°, occurred on the 21st, in 1846; and the lowest cold, 2°, on the 17th, in 1855. During the period 148 days were fine, and on 104 rain fell.

MEMOIR OF THE REAL "LAWRIE TODD."

T was somewhere about the year 1833 or 1834, that we met in the quadrangle of Edinburgh University a wee wee man, about 4 feet 10 inches high, clothed in very very long garments, the skirts of which reached to his ankles, and with a very low-crowned and very broad-brimmed hat upon his head. His feet,

like the brim of his hat, were out of all proportion to his body, for they were very large and very long; but beneath that broad brim there shone a beaming countenance, full of intelligence, benignity, and playful humour. It needed not to have his name announced, for the world had been made familiar with his portrait through "Fraser's Magazine," and we had no difficulty in at once recognising the living image of GRANT THORBURN.

Our woodcut is a faithful portrait of that original, and we learned that he was the model from whom Galt sketched his "Lawrie Todd." That sketch by no means pleased the model; it contained, he says, "scraps and mutilated extracts" of his history, and, as he proceeds, "I have always found that whatever business was laid to my hand, was best done when I attended to it myself;" therefore, "I think I owe it to myself to state the simple truth;" and we owe Grant Thorburn no merely customary thanks for having paid that which he considered a debt due to himself, for he has left more than one most amusing and most instructive record how he, an emigrant nailer, "landed on Gouverneur's Wharf, New York, with only three cents in his pocket, and his nail-hammer in his hand, and rose to have a seedsman's establishment the most extensive in America." This "suggests the inquiry, How was it brought about?" We will endeavour to show in his own words.

"I was born in Dalkeith on the 18th of February, 1773. My father was poor (some are cursed with rich fathers), honest, and industrious, and by trade a nail-maker. He was a very strict Scotch Presbyterian, a Covenanter, and, like his neighbour and prototype, Davie the father of Jeannie Deans, an honest man. Our cottage stood within two miles of Davie Deans's farm, within three of the Laird of Dumbiedike's mansion," immortalised in the "Heart of Mid-Lothian."

Passing over the incidents of his youth, and as he verged upon manhood, he relates—"In the year 1792, when the French Revolution had fairly commenced, and the pulpit and press were teeming with Reform, I joined the Societies of what were then called 'The Friends of the People,' and in London were termed 'The Corresponding Societies,' whose ostensible motive was to obtain the reform of parliament by a more equal representation; and in the winter of 1793, with seventeen more

of the members of the said Society in Dalkeith, I was marched a prisoner into Edinburgh. We entered the town marshalled two and two through a concourse of people, one woman among whom, when she saw me bringing up the rear rank, exclaimed in her broad Scottish dialect, 'The Losh presarve us! if the king be afraid of sic a little fellow as that, I dinna ken what will become o' him!'"

"The little fellow" was examined and discharged by the magistrates; but either he feared he might be led into overt acts for reform, or he was resolved to live where there was no king to fear or make afraid—at all events he sailed for New York with his brother in 1794. When they arrived they could not land on account of the expense of living on shore, for they had but six and a half cents between them. So says our hero, "My brother and I sat down on the deck, his feet against my feet, and a wooden-bowl of potatoes between our legs, and began to scrape the skins off from the potatoes. Whilst thus employed a hardware merchant came on board, and asked if there were any nail-makers? I caught the word, and answered I was one. He was a tall man, and looking down on me, inquired, with a tone of surprise, 'Can you make nails?' I answered quickly, 'I would wager sixpence (all I had) I would make more nails in a day than any man in the country.'" Thorburn knew he could make 3320 nails between 6 A.M. and 9 P.M., so he was tolerably sure of a triumph.

Thorburn and his brother were hired; they were industrious, obliging, God-fearing young men, so they were respected and prospered; but we must pass on to 1802, when he thus proceeds—"About this time the ladies of New York were beginning to show their taste for flowers; and in the fall of the year, when the plants wanted shifting, preparatory to being placed in the parlour, I was often asked (for he then kept a grocer's shop) for pots of a handsomer quality than the usual red earthenware. It came into my mind to paint some of my common flower-pots with green varnish paint. They sold fast, and to good advantage. In the April following I observed a man for the first time selling flower plants in the Fly Market. As I passed along I took a leaf, and rubbing it between my finger and thumb, asked him for its name. He answered, 'a Geranium.' This, as far as I recollect, was the first time I ever heard that there was a Geranium in the world."

Thorburn bought two of those Geraniums, sold them speedily in his "green-varnished pots," and soon found that it was a ready, profitable trade, and that the purchasers asked for seeds. This set him "thinking that if I could get seeds I would be able to sell them; but here lay the difficulty, as no one sold seeds in New York!" He soon arranged with the man "in the Fly Market" to stay at home and grow plants and seeds, whilst he, Thorburn, opened a shop and sold them. But war broke out; he attempted to grow seeds, failed, and in 1815 was released a whitewashed bankrupt, with a family to support, and but twelve dollars with which to begin life again.

"Lawrie Todd" was not the man to be cast down, for he through life strove to do what he ought to do, and one passage in his morning of life is a fair illustration of the whole until the shades of its night closed, so we will quote but one—

"One Sabbath morning some young men of our passengers called at my lodgings.

"Where are you going to-day?" said they.

"To church," said I.

"Oh!" said they, "let us go to Long Island, and take a stroll in the fields. Our health requires exercise after being so long on ship-board."

"You may go where you please," said I, "but I go to church. The last words my father spoke, as we parted on the shore of Scotland, were, 'Remember the Sabbath day!' I have not so soon forgotten his words."

"They went to the fields, I went to church; they spent a few shillings, I put a penny in the plate.* Some of them earned nine or ten dollars a-week; I only received five and a half. They would get a light waggon, drive off with some young ladies, spend five or six dollars, get caught in a thunder-shower—fine clothes and hats all spoiled—come home half-drunk, rise at eight o'clock on Monday morning with aching bones, sore heads, downcast looks, and guilty conscience. I went to church, rose at five o'clock on Monday morning with a sound head, bones and body refreshed and rested, entered the labours of the week with a clear head and quiet conscience. At the end of the year they had fine clothes, fine hats, and powdered heads, but I had a hundred hard dollars in the corner of my trunk. They, having lived fast, all died young; while I, in consequence of my regular living, have not been confined a day by sickness in fifty years."

In 1815, a friend having lent him 500 dollars, Thorburn again commenced business as a seedsman, and from that time his life was a long succession of prosperous and happy years.

The following example of his "Advertisement" in the public papers, is both characteristic and historic.

"In 1799 the subscriber commenced business with three pots of Geraniums, a monthly Rose, and 15 dollars' worth of seed. The seeds grew till they filled the whole continent—the Rose blossomed till it spread into a tree, and the little birds formed their nests under its branches. Presently there came forth a

* In accordance with a custom in the Scotch churches, where a plate is always placed at the door on the Sabbath to receive the free-will offerings of the congregation.

host of pretenders, boasting of what they could do; they did nothing. In 1818 appeared William Cobbett. This same Cobbett, in 1793-4-5, published the 'Porcupine's Gazette' in Philadelphia; its object was to prove to a demonstration that all republics were humbugs—that kings only had a divine right to reign—and that the Americans were a set of consummate rebels. The mob tore down his office, made "pie" of his types, and scattered his porcupine quills in their native air. He fled to England, returned to New York a full-blooded radical Democrat, and opened a seed-shop at 62, Fulton Street, where he sold ruta бага at one dollar per pound, and black pigs for ten dollars each. For a long space of time you could hear nothing in Wall or Exchange Streets, but Cobbett and his black pigs—Cobbett and his ruta бага. The consternation was similar to that at Frankfort, when the man rode through the streets with the long nose, and still the wonder grew whether the nose was a paper or a timber (wooden) nose. He vowed he would drive Thorburn from the boards with his black pigs and ruta бага, in less than six months. Before twelve he closed the concern, and again sailed for England. Naked he came into America, and naked he returned from thence; his whole goods and chattels (a few minor articles excepted) consisting only of ruta бага and smoked hams from the hind quarters of his black pigs; he shipped one case, however, which by some estimation was beyond all price—viz., a rough Albany deal board, formed into a square box, and in this box was deposited the profound skull and dry bones of the venerated Thomas Paine, author of "Common Sense," &c. Out of these bones Cobbett meant to have made political capital, but they were seized by the custom-house at London for duty, and sunk (if report speaks true) in the deep green sea.

Grant Thorburn

tical quacks in all countries and at all periods. It is but a few years since that our political jugglers turned the world upside down about Morgan, his dry bones and split skull; Louis Philippe, too, and his French radicals, must needs parade the bones of Buonaparte wherewith to make a bank political.

"But enough of this long preamble. It is only meant to let his friends know that Grant yet lives—his eye as clear, his head as sound, and his health as good as in 1801—and this being the first day of spring he is provided with the usual supply of goods

"From this subject it may be profitable to observe how similar are the movements of poli-

(as they say in Prarl Street) to accommodate his friends; and his being only a branch from the tree at 15, John Street, the seeds, on trial, will prove good. American and European flower-seeds just received. Bouquets prepared for the ladies in the neatest order. Catalogues gratis. Gentlemen supplied with gardeners, &c.—GRANT THORNBURN."

In 1833, on which occasion we saw him, he revisited his native land, and one of the most touching chapters in his journal, entitled "Men and Manners in Britain," is that in which he narrates a gathering at his native town of a select twenty-five, "the majority of them my school-fellows fifty years ago," and from whom he parted to meet no more, with "Auld Lang Syne." That volume was published in 1835, but the year previously had appeared his "Forty Years in America," which met with a very rapid sale, and lured him to repeat himself more than once; for his "Fifty Years' Reminiscences," published in 1845, and his "Life," in 1852, are only versions of his first literary production.

As we recorded last week, this exemplary man died in America last month, and within a few weeks of completing his ninetieth year.

THE ROYAL HORTICULTURAL SOCIETY.

THE annual Meeting of the Royal Horticultural Society was held at the rooms at South Kensington this day week. A report of the proceedings will be found in another portion of our present Number; but as our space is too limited to introduce the whole of the report of the Council, including the statement of accounts, we shall refer to them in the few observations we now intend to make. It has always been a great disadvantage that the Reports of the Council could not be procured till the Fellows entered the room on the morning of the Meeting, and only a few minutes before the chair was taken. It was utterly impossible for any one during that brief space to make himself sufficiently master of the financial statements so as to qualify him for making any observations on the upward or downward progress of the Society; and several of the Fellows at this Meeting feeling this, it was very properly resolved that in future the Reports be prepared a week before the day of meeting, and that any of the Fellows may be furnished with them on application.

Before the day of meeting vague rumours were afloat that the finances of the Society were again in a precarious condition, that notwithstanding the large amount which had been received during a season which for length and splendour few may live to see the like again, all was spent, and that the Society would have to raise money on loan to enable it to carry on even for the present year. We were, however, pleased to hear from the Chairman that although "the Council would be glad if anybody would advance them some money, for he had no doubt they could spend it; still, so far from requiring to borrow, they had £6000 or £7000 in hand." This, doubtless, was a more cheering statement than the one which we had heard; but, cheering as it might have appeared to the Meeting, the impression it made on our mind was one of blank disappointment. It appeared by the statement that the receipts on Revenue Account had been £31,059 6s. 1d., and on Capital Account £17,021 14s. 3d., making in all £48,081 0s. 4d.; and we certainly expected to have heard that the Society had at their credit a sum beyond comparison greater than that stated by the Chairman. Twelve months ago we were told that the Society had nearly £16,000 of invested capital, and we had been living in the fond delusion that this was still safe in India debentures or other equally safe security; but when we are told that not only this and the whole of the £31,000 Revenue have vanished with the exception of £6000 or £7000, we naturally feel a strong measure of disappointment.

The statement, however, seemed satisfactory to the Meeting, for then the subject dropped, and the business was mainly confined to the complimentary expressions towards the Council from Colonel Challoner and Mr. Bateman, and to those less complimentary from Mr. Carter Wood. These, however, are small matters in comparison to the more vital question of finance, which ought to form one of the leading subjects at such a meeting. It is one which has always been uppermost in the affairs of the Society; and as the Fellows have an opportunity only once a-year of meeting to discuss them, every facility ought to have been provided to enable them to do so.

The accounts appear to us to be very complicated. Last

year they were arranged under four heads; this year they form nine. Last year we had a statement of "Assets and Liabilities," this year we have none; but are obliged to wade through a maze of facts, figures, and cross entries to our great confusion and bewilderment.

After devoting a considerable amount of time, and no small application, we have endeavoured to do for our readers what the Council have failed to do for the Society; and have presented in the following statement what we conceive to be the actual condition of the finances. We have in fact prepared an account, showing the available assets and liabilities, with the view of finding out where the £6000 or £7000 are, which the Chairman stated were still at the disposal of the Society.

ASSETS.			LIABILITIES.		
	£	s. d.		£	s. d.
On capital account.....	7200	0 0	On capital account.....	241	14 1
Balance on private account.....	485	1 10	Balance against ditto.....	7871	19 5
Ditto on composition account.....	5469	6 8	On private account.....	1755	7 6
Ditto in hands of accountant.....	5	19 3	Balance on rent account.....	295	5 9
Ditto in hands of the superintendent.....	146	8 0	Balance.....	3141	9 0
	<u>£13,306</u>	<u>15 9</u>		<u>£13,306</u>	<u>15 9</u>
Balance in favour of the Society.....	3141	9 0			

Such, then, is what we conceive, after all the investigation we can give to the subject, to be the real state of the Society's finances; and that instead of between £6000 and £7000, there is but a trifle over £3000, out of an income of £48,000!

The next question that naturally follows is, Where has all the money gone? This we have not time nor space to enter upon at present, but next week we shall endeavour, if possible, to clear up this point also.

COUNTRY MEETINGS OF THE ROYAL HORTICULTURAL SOCIETY.

I AM quite pleased with the article in your impression, February 3rd, from the pen of Mr. Anderson with regard to the establishing of a horticultural society of a migratory character. His remarks are to the point; and I, for one, have no doubt such a society would be found to work well, either in connection with present local societies or by itself. Like all others it only wants a beginning.

Could not the present Royal Horticultural Society hold a meeting—say at York, in connection with the present year's fête held there, which your correspondent does not mention in his list, although I believe second only to the great shows in London, as the advertisement says, and very superior to many held under Royal auspices there? As a proof of this I may say that one of the London exhibitors, who invariably takes the lead in the open class for Pelargoniums, was signally defeated at York.—EBORACUM.

CULTIVATION OF GLOXINIAS.

WE admire some plants for their handsome foliage, others for the beauty and size of their flowers, and some for their graceful habits of growth; but when we find these three good properties combined in a great measure in the Gloxinia, we are rather surprised that it is not more generally appreciated and cultivated. Its fine, rich, trumpet-like flowers—either of distinct colours, white, crimson, blue, purple, or pink, striped, mottled, edged, or blotched with carmine, blue, bright rose, and blush—either rising boldly above or resting on its fine, rich, velvety large, and beautifully-veined foliage—give to the whole plant when properly managed, a fine, massive, and graceful appearance, like a bouquet handsomely and artistically arranged.

Although Gloxinias generally receive the same treatment as other tropical plants, and at Kew they succeed admirably in a stove temperature, nevertheless, amateurs and others who have a warm greenhouse and a frame heated by dung can grow them to as great perfection as where they are allowed a higher temperature.

Sow the seeds in pots of light sandy peat in February; fill the pots half full of crocks, over which place a layer of moss and

peat, after which sift a little peat and sand very fine, distributing the seed evenly thereon. It requires no covering with soil. Water with a very fine rose, cover with a bell-glass, and plunge the pots in bottom heat. In ten days or a fortnight the plants will appear. Give air by degrees. When they have formed three or four leaves transplant them into 60-sized pots; and if properly supplied with heat and moisture the plants will bloom in the autumn of the same year. They should not be dried-off until the second year, as the small fibres are not sufficiently strong to cause them to start vigorously in spring. This remark is also applicable to young plants raised from cuttings.

The stock can be readily increased, as almost every part of the leaves will form plants if a portion of the midrib be retained in each cutting. Divide the leaves transversely, place them in pots of fine sand, cover with a bell-glass, and plunge in a strong heat; in a short time callosities will form at the base of the cuttings. Repot in good sandy peat, replunging and covering with a hand-glass, giving air occasionally. If the plants to be propagated are very choice, remove them into a large pot, making incisions on the midrib of the lower leaves, placing a few pebbles on the leaves to keep them to the soil: this is the safest method. They will soon root if a good heat is maintained, and may be repotted immediately.

February or the beginning of March is the best time for starting the old plants after their winter rest. In potting, the old soil should be carefully removed from the roots. In planting, press the roots gently on the surface of the soil, and give them no water for some time. The soil should consist of half peat, one-fourth loam, and one-fourth leaf mould, mixed well together, and used in a moderately rough state. A thorough-good drainage of potsherds is indispensably necessary. As they progress in growth and fill their pots with roots they are to be liberally shifted, not exactly on the one-shift system, but approximating to it—that is, from a 48-sized pot to a 24, and ultimately to a 16, where they will attain a size, luxuriance of growth, and profusion of flowers suitable for exhibition at our horticultural shows or for adorning the conservatory. The soil should be gradually enriched with some well-rotted dung until they receive their last shift in which they are to bloom, when more loam with less peat and a liberal addition of rotten dung may be given, the soil being used in a rough state.

After they are all potted remove them to a frame where the temperature is about 60°, and when they have commenced growing give them a little water, increasing the quantity as they advance in growth. A little air must be given in fine weather. During their season of blooming a watering with weak liquid manure (sheeps', pigeons', fowls' dung, or guano) may be given occasionally, which will increase the luxuriance of the foliage and the brilliancy of the flowers. When done blooming watering to be gradually discontinued, and at last entirely dispensed with, when they should be removed to any out-of-the-way shelf in a warm greenhouse for two or three months until February, when the season for a fresh growth arrives. *Gloxinia caulescens*, which is unlike any of the others in habit and manner of growth, with a few other species continue in a growing state all the winter.

The following are good sorts:—

Alba grandiflora.—Pure white.

Argyrostigma splendens.—Deep purple, with white throat, and foliage beautifully striped.

Anonyma.—Blue lobes, margined with lavender; white mouth and throat, spotted at the base.

Aeme.—Blue lobes, edged and prettily marked with white; violet throat.

Baronne de Vrière.—Mottled lilac.

Beauty.—Pink lobes; pure white mouth and throat.

Brilliant.—Bright crimson, the lobes margined with rose; rich violet throat.

Carminata splendens.—Fine rich crimson, large flower.

Celestial.—Rose lobes; throat encircled with deep violet; base of the tube white spotted with brown.

Cupid.—Light blue lobes with white markings; pure white throat.

Daphne.—Pink, edged with white.

Fairy.—White tube and lobes; the mouth peculiarly encircled with violet crimson.

Favourite.—Bright rose, shaded with crimson; throat encircled with violet; white tube.

Godfrey de Bouillon.—Fine blue.

Grandis.—Blush, with carmine throat.

Maria Van Houtte.—White and carmine.

Lauretta.—Blue, marbled with white.

Model.—White, tube pink shaded with violet.

Madame Malibran.—Bright rose.

Napoleon.—Carmine red and white.

Princess Alexandra.—White lobes, margined with blue.

Princess Beatrice.—Blue, each lobe spotted with violet; pure white throat.

Petioniana.—White, with crimson throat.

Spectabilis.—Purple.

Victoria Regina.—Lilac blush, with intense purple throat.

Virginie.—Blush, under lobes bright crimson; violet throat.

W. KEANE.

A FEW DAYS IN IRELAND.

CARTON.

(Concluded from page 118.)

BUT though the scenery in front of the mansion is richly picturesque rather than bold and striking, there is no want of the wild and romantic at Carton, and especially at the glen through which winds the river Vye. Through the natural and art-enhanced attractions of that glen, Mr. Hamilton, of Ham Wood, drove us to Carton. Now the noise of the little river is heard trattling with some huge boulders, and then its quiet murmur as it passes over a pebbled bed; now it is lost amid overhanging masses of foliage, or dimly discernible amid long reaches of bullrushes; and anon it comes before us as a quiet pool, reflecting like a mirror the surrounding scenery. The banks, and especially the right-side one, along which we pass are equally diversified. Here are steep craggy rocks with the clefts of their faces relieved with lichens, mosses, *Ceterach officinarum*, and *Asplenium Ruta-muraria* and *trichomanes*—there are lofty mounds, with luxuriant timber, and trailing Ivy, and Ferns disputing for the undergrowth, with some favoured young Conifers standing in a conspicuous position. Anon we come to mounds composed, seemingly, of decayed rocks and wasting wood, covered with large breadths of the common Polypod, or relieved with masses of the *Blechnum boreale*, or fields of *Scolopendrium*; and then again and again, and varying with these, on steep banks and mantling over precipices, no end of *Cistus*, *Hypericum*, and *Helianthemum*, &c., all testifying that here the earnest enthusiasm and the correct judgment of the late Duchess are as manifest as in the other parts of the demesne. Before we have time to weary we come in front of a deep cascade, and on its other side are delighted with one of the most beautiful of artificial lakes.

Crossing above the cascade to the opposite bank, we pass through embowering trees to the cottage and cottage garden. Here we found fine specimens on the lawn of deciduous and evergreen trees, but something of the idea of rusticity was maintained throughout. We cannot be sure of the size of the large flower garden, but its striking characteristics were twofold. First, circular arches for climbers, with rich wreathed festoons going to a good height at the centre. Then secondly, though there were plenty of *Calceolarias*, *Geraniums*, and such Crystal Palace Dahlias as for height and fulness of bloom we have scarcely ever seen equalled, the grand features were beds of *Pentstemons*, *Fuchsias*, *Phloxes*, *Asters*, *Antirrhinums*, &c., in the good old flower-garden style. Another very attractive though somewhat sad subject was the fine old man, the gardener, Mr. Abercrombie, packed in a large easy chair on wheels, basking in the sun and taking cognisance of the work, as from rheumatism and paralysis he had long been unable to walk. Long may he reign in his little province under such kind and generous sovereignty.

Several pits and frames out of sight supply the plants for this garden, and five men are regularly employed to keep it and the lawn, &c., round it in order. The cottage, chiefly in the Swiss style, is for the residence of the gardener, and a portion is set apart for the family and their friends. The dry rot had attacked the wood, and the whole was undergoing repair, the roof being renewed by an outside covering of small rounded tiles of a dull colour so as not to interfere with the general outline. On entering the large reception-room one felt as if carried by an enchanter to revel amid the gorgeous beauties of fairyland. The whole of the arched and ribbed roof and walls (unless where there was a mirror to reflect the beauties and enhance the dimensions), was covered by shells of every imaginable size, form, and colour. The beautiful arrangements, the exquisite designs, and the contrasts, the blending and shading of colours, must be seen to be

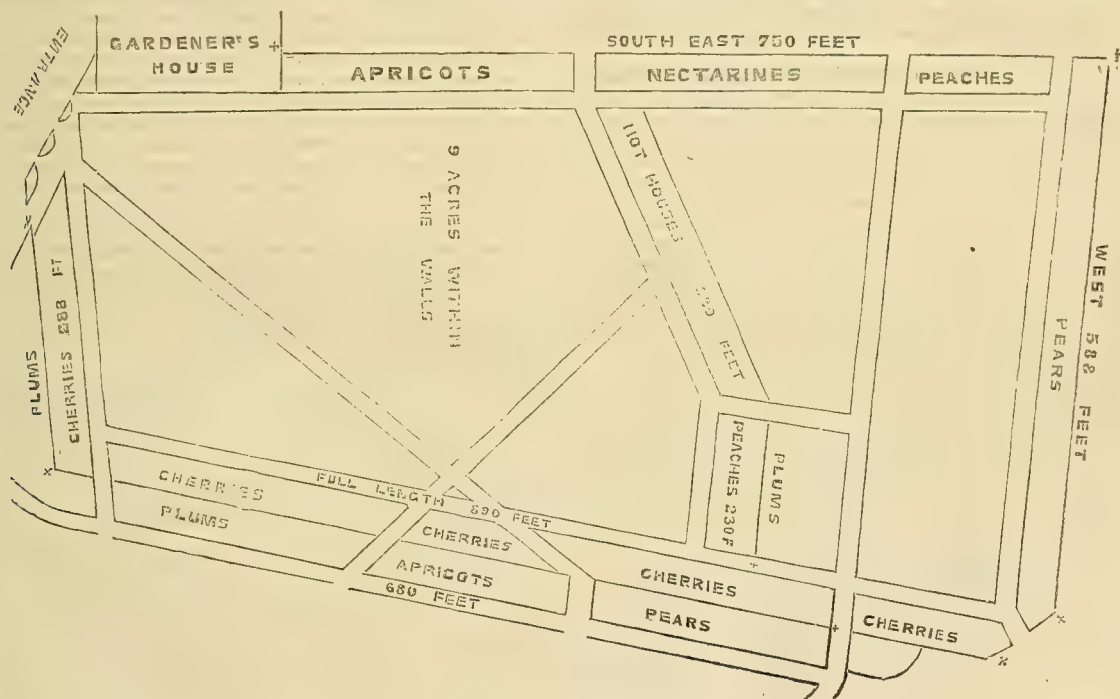

appreciated. We forgot how very long a time was required to finish this work. It remains a monument of the artistic and refined taste of the late Duchess, who, we were informed, planned all the arrangements and had every arch and panel fitted on the table, or the floor, before the shells were fixed into their places. Delightful as were the effects under a shaded light during the day, it must be still more dazzling under a strong light at night. In our boyish days we have experienced ecstatic delight, lolling on a hedgebank and reading the poems of Ossian; but no such hall as this could ever have been imagined by the warrior poet in which to hold the feast of shells.

We can well understand the interest that the noble Duke takes in this lovely spot, even from the force of past associations. Here we met and were introduced to him as he was superintending these repairs, and carrying an axe and a saw over his shoulder in regular woodman carpenter-fashion, and no doubt owing much of the hale vigour he possesses to such exercise and employment in the open air. Like other Irish gentlemen he playfully quizzed us about the barbarism of Ireland; and most kindly alluded to signs of improvement, and his hopes of still greater advancement when ignorance and prejudice should be more removed. If we have helped at all to give a better idea of what is doing in Ireland, these papers will not have been written in vain. Much of the success of the Duke in effecting improvements and inducing others to imitate his example we should be inclined to ascribe to his large-hearted kindness and courtesy. In converse you are so apt to forget the dignity, and to esteem

the man, that ever and anon the rough doric but expressive lines of Burns respecting Lord Daer come tilting over the memory—

"The fient a pride, nae pride had he,
Nor sauce, nor state, that I could see,
Mair than an honest ploughman."

In returning, and crossing the bridge at the cascade, we must notice two things. First, the strong, almost violent, contrast between the river below and the noble lake above, the first in its natural state and well supplied with weeds and rushes, but in unison with the character of the glen; the second, in its bright silver sheen without a weed or a rush on its bosom to mar the rich picturesque effect of its lawn and wooded banks and islands. Again: We have rather an imperfect recollection of the bridge, but the impression left on our mind is, that it is more in character with the glen than the massive splendour of the lake. The lovers of strong contrasts would prefer matters as they are. The lovers of the harmonious would prefer a dash of uniformity between the river immediately below and the lake above the cascade which dams back the water. There are five islands on the lake, one of which is called the Prince of Wales's Island, from being finished on the day on which he was born, and a Wellingtonia was planted on it by His Royal Highness on his visit to Carton in the summer of 1861. We should roughly estimate the size of the lake to be about sixty acres. The last improvements cost above £2000. The purity of the water and freedom from weeds are secured by firmly macadamising and grouting the bottom of the lake, and, in addition, forming an

PLAN OF KITCHEN GARDEN AT CARTON.

open culvert deeper along its centre, by means of which any mud, &c., that may accumulate can be removed.

Leaving this fine lake, we cross the park as a near cut to the kitchen garden, which contains nine acres within the walls. Instead of a description we will merely mention a few prominent points. First, there is a large commodious gardener's house close to the main entrance, looking very picturesque with its walls covered with Jasmines, Roses, and Honeysuckles. As a general rule, gardeners' houses are much more comfortable and suitable in Ireland and Scotland than they are in England. There have, of late, been many worthy exceptions, but it is too true that many gardeners' residences are still little better than sheds. In other cases, in addition to inconvenience and want of room, the house is often a mile or more from the garden, and very likely no young man kept on the premises, and yet forcing must be attended to. Can we really have any sympathy with gentlemen when they complain of their coal bill in such circumstances? Could any reasonable man find fault with us if

we adopted means which would prevent the necessity of watching the changes in the sky, and after the labours of the day trotting between house and garden and house for the best part of the evening? The true remedy is to enable a gardener to take his lantern and examine the condition of his houses in a few minutes.

Secondly, fine massive gates admit to the main entrance, with a walk to the right, and a walk to the left, and a walk in a diagonal line right before you. These diagonal walks, as in the case of Lough Crew, take away the sameness of square quarters, though, perhaps, lessening simplicity in the modes of cultivation. These walks, like those in the pleasure ground, were examples of cleanliness; and by the sides of the main ones low rows of flowers were grown. We noticed the best rows of *Nemophila insignis* we ever saw in the autumn, by itself, and also mixed with *Mignonette*.

Thirdly, vegetables for the coming winter seemed to be abundant, and fruit trees looked healthy and well stored with buds.

Fourthly, the walls were of great extent—3974 feet in length, and 14 feet in height. The trees, and especially the younger ones, were in excellent condition; and each kind of tree, as Peach, Apricot, Cherry, Plum, Pear, &c., was kept to its appropriate wall—thus, in addition to other advantages, securing more variety than any mere mixture could accomplish.

Fifthly, most of the walls were in excellent order, but others were showing signs of rottenness and decay. These were all being thoroughly repaired; and to enable the work to be properly done men were taking up large Pear trees, pruning the roots, and covering them over until the wall was ready to receive them. Lengths of wall so managed in 1860 were looking beautiful in 1861, after being replanted in fresh soil. Several more borders and walls have since been done in the same way, and younger trees becoming too rampant have also been lifted and replanted.

Sixthly, besides a large house, &c., in the Melon-ground, the main range of houses is 320 feet in length, 14 feet in width, and 14 feet in height at the back. Neatness and order were everywhere apparent, with neat paths near the back of the vinerias. The range is divided into four vinerias each 26 feet long, four Peach-houses ditto, and a Fig-house and conservatory in the centre. The wood in all the earlier houses was ripening well, and in the late vinerias there was just too heavy a crop. The Vines had been given to shanking, but were cured, though old plants, by lifting and replanting in fresh soil. The vinerias, Fig-house, and conservatory, and houses in Melon ground, were most efficiently heated a few years ago from one boiler by Mr. Meredith, Garston, Liverpool. The Peach-houses are still chiefly managed by flues.

Lastly, though in the vinerias and in the regular plant-house there were many of the more common and fashionable plants nicely grown, there seemed to be a want of that rarity and great variety in the way of collections which we would naturally associate with such a magnificent place. We also forget noticing much in the way of pits—those useful auxiliaries for forwarding early fruits, flowers, and vegetables, and which must be necessary to Mr. James even for securing plants for the flower garden, unless, like people in our small way, he turns his fruit-houses to such purposes in winter. We regret very much that, owing to a previous arrangement, we had so little of Mr. James's good company; as, had we laid him under contribution for a day, we might have told a more definite story about Carton instead of confining ourselves to its more salient points.

The home demesne consists of more than a thousand acres of rich fertile land, 50 of that being in meadow, 50 under crops, 520 in pasture, 314 in woods, and about 80 in water and roads. The whole is devoted to the keep of a large stud of horses, a splendid lot of milch cows, and a large stock of bullocks and sheep, to meet the supply needed for such a large establishment. A good number of horses and a large staff of men are constantly employed in carrying on improvements. On leaving Carton we could not help wishing that the noble owner might long remain to stimulate such industry and improvement, and that when, in the course of nature, he should be called home, there should be son, and sons, and sons to come, to inherit not only his honours and his dignities, but also that warm-hearted kindness, that strong faith, and firm hope which prevented him, even in the darkest times, from ever despairing of the future greatness and prosperity of the Emerald Isle. R. FISH.

THE ROYAL HORTICULTURAL SOCIETY'S ANNUAL MEETING.

THE Annual Meeting of this Society was held on Tuesday last, the 10th inst.; and in consequence of some unsatisfactory rumours which had been afloat for some days previously with regard to the Society's financial condition, it was looked forward to with some degree of uneasiness by those interested in the Society's welfare. The chair having been taken by Sir C. Wentworth Dilke, Bart., the first proceeding was to read the Report of the Council, upon which the Chairman invited discussion.

Colonel CHALLONER then rose and said—That as the present was, he believed, the only moment when the Fellows could address the Council he would make a few observations. He expressed great satisfaction at the way in which affairs had been carried on, and congratulated the Council on the success attending their exertions; at the same time it was impossible to bring forth arrangements to which exception might not be taken by

some. He, for one, objected to the day fixed for the inauguration of the Memorial of the Exhibition of 1851 (the 5th of June), that being in Ascot week, and, consequently, many would be unable to attend the ceremony who would desire to be present.

Then, he had been asked by a number of the oldest members of the Society, to make a request to the Council. These members felt that the character of the Society had not been raised but lowered by the adoption of 6d. admissions to the public, and, paying four guineas a-year, they had imagined they had some guarantee for the character of the company. They, therefore, wished for a more restricted admission of the public.

The next point was the gardens. Nothing could be better than the flat geometrical parterres, but those on the side of the sloping banks were contrary to all rules of landscape-gardening, and he would wish to see them removed. He concluded by observing that a vote of thanks to the Council would not be misplaced on account of their great attention to the interests of the Society.

Mr. J. CARTER WOOD then severely adverted to the bare and desolate appearance of the garden in winter, and the state of the arcades, which looked like brick sheds; and he thought that the members were entitled to expect the Council to give them a quiet and comfortable walk in winter, otherwise he considered the Society would not go on increasing.

In connection with this subject a letter from Dr. Cooper, containing suggestions for the improvement of the garden was read. It stated that the arcades were generally admitted to be in their present state unsightly, neither affording shelter in winter, nor shade in summer. It was, therefore, suggested that they be covered with glass, heated, and plants introduced, so as to form a winter promenade. This might be effected at a cost of £10,000. With regard to the conservatory, a marble fountain should be erected in the centre and two aviaries in the gallery, and tessellated pavement should be laid down. As to the garden, planting should be carried out, but that would be best left to Mr. Eyles.

Colonel WILSON said he did not agree with Colonel Challoner about visitors not being admitted for 6d., such admission enabling a vast number of persons to see the gardens who would not otherwise be able to do so; and he thought that the public might be admitted one day a-week on these terms with advantage to themselves and the Society. He congratulated the Council on the prosperous state of the Society.

Mr. H. G. BOHN was glad to find the gardens prosperous, and hoped that in future the Reports would be sent out a week or ten days before the Anniversary, as it was impossible to form an exact opinion of the balance-sheet when only received a quarter of an hour before the Meeting. He had heard that they had spent all their money, and that they would require to borrow to enable them to go on; he hoped the Chairman would inform the Meeting of the exact state of the finances.

Alderman COPELAND thought that, had it not been for the exhibitions which took up so much of the time and attention of the officers, the gardens would have been better; but even as it was everything was well done, and evinced activity and good management. With regard to converting the arcades into a winter garden, he did not see how the money was to be raised except by doubling the subscriptions.

The CHAIRMAN in replying to the various observations and suggestions which had been made said, that with reference to the day fixed for the uncovering of the Memorial (the 5th of June), there was a difficulty. That day was fixed upon as being the anniversary of the opening of the garden by the Prince Consort, the Exhibition of the Botanic Society was on the 3rd, the Society's own Shows were a week before and a week after, and he did not see how it could be bettered. If it had been wished, the highest personage in these realms would have uncovered it herself; but he felt—they all felt—that such a mournful task would be demanding too much of her fortitude of mind. He had to a certain extent been consulted in the matter, but he would endeavour to get the opinion of the Prince of Wales, still he had very little hope of a change in the day; nevertheless, he would consult those connected with His Royal Highness. He thought that the uncovering of the Memorial would be the first public occasion on which the future Princess of Wales would appear after her marriage.

Colonel Challoner had taken exception to the admission at 6d. In the present year there would be no 6d. or 1s. admission, the public would only be admitted on payment of 2s. 6d. He

thought it would take much time before the taste of the general public would be sufficiently advanced to require the admission to be reduced to 6d., especially when there were such attractions as Richmond Hill. But when all things were settled he thought one day a-week might be devoted to their admission at this price.

Then with reference to the parterres on the slopes, they have the advantage of looking bright in winter, but there are many points in Mr. Nesfield's plan which may be modified. He advocated the introduction of Lilacs, Laburnums, &c., into the gardens. A great mistake was made last year in the grounds being rendered beautiful at a time when the public could not enjoy them. With respect to the conservatory, of course a good deal could be done, but the cost was a consideration. He thought that a portion only of the parterres should be retained, as they required an enormous quantity of bedding plants to fill them.

With respect to the arcades, he thought not much could be done at present. Government proposed last year to take a considerable portion of the arcades, but for some reason the proposition fell to the ground. Negotiations, however, were going on, and he believed that some portion of the ground would be covered with public buildings; and, if so, something would be done with the remainder. He was inclined to vote for glazing the arcades, but not for heating them on account of the expense, and without heat many plants could be grown. Besides, the arcades were not the Society's under agreement, and though they could use them they could not pull them down or alter them without the consent of the Commissioners of 1851. He quite agreed as to the desirability of a fountain in the conservatory, but thought the latter was too small for one. He also acquiesced in the suggestion of tessellated pavement if the expense could be incurred, but that was the obstacle.

With regard to the finances, it was not true that the Society would require to borrow more money to carry on. If anybody would advance them a little money he had no doubt they could spend it, but they were not quite come to that pass yet; they had still £6000 or £7000 at command.

Two points still remained to be alluded to. The first was, that it was always contemplated to have a reading-room with books and periodicals, and it is proposed to fill the recesses in the Council-room with such and convert it into a reading-room, which shall be open every day except Sundays and *Jefe* days. The next was—that they could not separate without taking notice of the retirement of Dr. Lindley. He had worked for forty-one years in the interests of the Society in a way that few have strength to support, and the Council had come to the decision that a portrait of him should be taken at their own charge, as it was they who had been most in contact with him, and they alone knew the enormous amount of work he had had to go through.

Colonel CHALLONER here called attention to "that tent—that horrible tent," which had been remarked upon by many, and he asked if an alteration could not be made.

The CHAIRMAN in reply said—That half of those whose opinions were taken were in favour of the colonnades, and the other half in favour of tents. The one party alleged the superior dryness of the arcades, the other that plants never look so well as under tents. The tents last year were on too large a scale, and though erected in a sheltered spot one came down. Practical men were quite unanimous in favour of tents as being the most suitable, but if Government should take a portion of the arcades there would then, doubtless, be a permanent building.

Alderman COPELAND suggested on the part of the members that Dr. Lindley should be presented with a piece of plate.

Mr. BATEMAN bore willing testimony to the constant urbanity and assiduity with which Dr. Lindley discharged his duties, and thought something more should be done than the portrait.

Colonel WILSON moved that the Council be requested to adhere to the day fixed upon for uncovering the Memorial, and the motion was seconded by Mr. Bohn and carried.

The thanks of the Meeting were next unanimously voted to Dr. Lindley.

It was then moved by Mr. BOHN, and seconded by Colonel WILSON, that the annual report and ballot papers be circulated among the members a week previous to the Anniversary, and this motion was agreed to be carried out, as far as practicable, without a division.

The ballot for new members of the Council and officers for the ensuing year was then proceeded with, when Sir Daniel Cooper, Bart., the Rev. Joshua Dix, and J. Kelk, Esq., were

elected new members of Council in the room of Earl Somers, the Bishop of Winchester, and H. Pownall, Esq., who retire; William Wilson Saunders, Esq., Secretary, in room of Dr. Lindley; and J. Clutton Esq., Treasurer.

WEEDS ON GRAVEL WALKS.

YOUR correspondent "JARDINIER" should, if he has not already done so, try sulphuric acid solution upon these great disfigurements. I was very much troubled with weeds, and particularly that exceedingly annoying one, Couch, on my paths about two years ago, and tried both powdered salt and solutions of corrosive sublimate without much success. Either of these would certainly destroy Groundsel, and the small annual grasses, but against Couch, Dandelion, and Dock, they were powerless. My ground being a strong clay, mere hand-weeding was nearly useless, the longer roots breaking in the soil, and reappearing fresh and lively in a few weeks. I at last tried a solution of about a pint of acid in four gallons of water, and I had a complete victory over my enemies, the mixture appearing not only to destroy the tops of the weeds, but also to corrode the roots themselves. The common vitriol can be procured at any oilman's for 3d. a-pound, and probably for less, for a large quantity. I apply it (mixing it in a well-painted pail) with a small watering-pot, a slight sprinkling being quite sufficient for ordinary weeds. A weaker mixture than the above would kill Groundsel, &c. If the path hisses softly, the solution has sufficient acid. This mixture does not make the path "sodden" like salt. It should be put on in dry weather, or the rain will weaken its effect, besides washing it down to the edgings, where it may exercise its virtues undesirably. If this hint is of any use to your correspondent he is quite welcome to it from—LEX.

[Does not the acid injure boots and shoes that touch it?—EDS.]

MILDNESS OF THE SEASON.

It is generally acknowledged that the present winter has hitherto been an unusually mild one. In some localities, however, it appears to have been less so than in others. Cornwall has experienced sharper frosts than Kent; while, in the opposite corner of our triangular-shaped kingdom, Northumberland, I am told ice was 4 or 5 inches thick in November; and in some of the central counties frost, more or less severe, was also experienced at that time. Since then the two months we generally experience the greatest amount of cold in (December and January) have passed away with fewer frosty days, and those less intense, than we have often known in April; and up to the time I write (the 10th of February) it still continues mild. I speak of this district, Kent, where the sharpest frost we have had since the 23rd of November has only been 5°, the thermometer sinking to 27°.

It is almost needless to say that such an unusual period of mildness is of rare occurrence, and it is equally singular that vegetation should have made so little progress during that time. The buds of Gooseberries are but little in advance of what they usually are in ordinary winters, and the same is the case with other trees.

Herbaceous vegetation has, however, kept growing; fields of Turnips as well as grass fields showing the rich tender green of spring, and in gardens the Borecole and Cabbage tribe have had no check. Unfortunately, the latter may not have had sufficient to prevent its running to flower, which evil is likely to befall Celery a month before the usual time, and autumn-sown Peas are likely to be too vigorous to stand the cold that may possibly come yet.

In the flower garden the frost we had in November so far injured or killed most things that they were then removed; but I find some variegated Geraniums that were left in some rustic vases, in no way protected excepting by their own leaves, are alive and sprouting out afresh in their stems; and Calceolarias have grown considerably, both old plants left in the ground and the cuttings put into a cold frame in the latter end of October; the latter had grown so much that I was obliged a few days ago to thin them out, and put in another batch of cuttings in the same place, which I have no doubt will do pretty well.

I may add that some cuttings of Geraniums were put into a cold pit early in September to strike in order to be taken up

and kept in boxes and pans elsewhere during the winter, but they were not all wanted, and consequently were left to their fate in this cold pit, with nothing over them but a single light, and they almost touching the glass; yet the frost we had at that time, and the damp and neglect which followed, have not entirely killed them, as several are still alive and pushing out fresh leaves amongst the mass of dead and decaying ones by which they are surrounded. The pit is quite exposed, but their having abundance of air sideways, is, perhaps, the reason of their escaping the evil effects of so much damp weather; for, although we have not had many heavy rains in the last two months, my register records twenty rainy days in December and twenty-six in January, with little sun either month. In fact, the absence of sunshine these two months has been anything but favourable to the preservation of bedding Geraniums in the places they are usually kept; for, it being too mild to require fire heat, there was an unwillingness to burn fuel to no purpose, while at the same time there was not that dryness of atmosphere necessary to protect a tender half-rooted cutting from succumbing to the decaying influences by which it was surrounded. Other plants more able to withstand damp than fire heat have, of course, suffered less; and many Verbenas and such like that were left out of doors will doubtless produce cuttings that may be turned to account; but all ours were destroyed when they were no longer ornamental.

It would be easy to point out other instances of the mildness of the season, as Primroses having been in flower since September, and Fuchsias budding up to the tip ends of the last year's shoots; but anxieties are more directed towards the future. And if any confidence can be placed in predictions it is easy to find out what is said about the weather to come. Unfortunately the mistakes of the weather-prophets as to the past give us little confidence in their foretellings of the future.—J. ROBSON.

SELECTION OF SEEDS FOR A KITCHEN GARDEN.

IN a late Number of THE JOURNAL OF HORTICULTURE was given a list of vegetable seeds suitable for an ordinary kitchen garden. As regards quantity, this list gave just such a proportion of each kind of seed as I should choose for a kitchen garden of, say, an acre; but as regards the quality and selection something more is required, and on these points it is no easy matter to give any definite statement suitable for all localities and all kinds of soils. I have chiefly had to deal with small kitchen gardens, considerably less than an acre in extent, and of various kinds of soil, from a light loam to a stiff marl, and yet I have found that the quality or selection of seeds is of far less importance than the management of them, and the cultivation of the soil.

It will be seen from my former remarks, that I regard plenty of room as one of the most essential points in good culture. However small the space may be, let the quantity sown be small in proportion, so that when the plants grow the air may circulate about them, and the light shine on them from all parts, and they will not be drawn-up into making a superfluity of leaf and stalk, which wastes the energies of the plant in making growth which is not required by the cultivator.

I also regard moisture as most essential to vegetation during the period of growth, and where the soil is of such a nature that moisture quickly evaporates, endeavour either to prevent its doing so by mulching, or supply the loss abundantly from the water-pot. Beyond this, plants require sustenance, to be given in the form of manure, which should be in such a state that they can appropriate it at once. Again: The surface of the soil should be pulverised, and subjected to the action of the air as Nature intended it should be. I do not find in Nature any such thing as throwing up the ground to the surface from a depth of 3 or 4 feet, in order that plants may luxuriate in the soil thus thrown up. In this I think we are apt to steer too wide of what Nature teaches, and this applies more particularly to small gardens, where a larger amount of labour is given in proportion to what gardens of greater size receive. I think if these points were fully considered and acted upon, there would be little difference found in the result of the management of different kinds of soil; at least, I have found the difference not so great as many would have us believe.

With regard to the selection of seeds, I can confidently affirm, that report appears to me to exaggerate the qualities of

various sorts, and that what are spoken of as distinct varieties have turned out so nearly alike, that the difference has been imperceptible to the ordinary observer, and that more difference is found to result from different management, difference in the season, and like causes, than from any difference in the sorts. I have grown a dozen varieties assumed to be distinct, of late Broccoli, and found no more difference in them than if they all had come from the same packet; and every reader of THE JOURNAL OF HORTICULTURE must be aware of the number of names given to what have proved to be one and the same sort. But, then, we know there are sorts that really have a distinction, and this sometimes of a very wide nature; for instance, in the various sorts of Peas, where none would mistake the Emperor for the Scimitar, either in the seed, or in any stage of growth. The Potato and the Lettuce also offer similar distinctions. It is a gardener's duty to make himself properly acquainted with these distinctions and other points in the selection of seeds, so that he may be enabled to lay before his employer a list in every way suitable for a proper succession, adapted to the space, and also to some extent, if possible, to the nature of the ground.

I have seen much relative to the making of seed lists, and as a rule, I have observed that quantity is given the precedence, and that the selection is either a yearly repetition, or that such sorts are inserted as are most highly recommended in the catalogues; but the employers find no perceptible difference. Some particular crop may, it is true, come extra fine, and this more by chance than management, for it is tried again the next season with a very different result. I have been in the habit for years past of making out a fresh list every season, and have tried such sort of Peas, &c., as are reported of superior quality; but I have also found that suitable treatment is necessary to bring out those superior qualities, and what that treatment is will be apparent to any observer. It is no use trying to evade the fact, that to bring out the good qualities of any plant, it must be in the hands of one who understands how to do so, and is willing to apply the means.

A seed list such as I should make out for half an acre of kitchen garden would contain about 5 quarts of Peas, 1 each of Sangster's No. 1, or Emperor, Auvergne, Champion of England, Imperial, and some tall sort, as Ne Plus Ultra or British Queen, for if properly treated these bear largely and continuously; from 2 to 6 quarts of Broad Beans, according as they are liked or not; 1 pint of Scarlet Runners; 1 of Dwarf Kidney Beans; Carrot, 2 ozs. of Early Horn; 3 ozs. of a large keeping kind, as Long Surrey or Altringham; 2 ozs. Parsnip; 2 ozs. Beet; Onion, White Globe, 2 ozs., Lisbon, 2 ozs.; Spinach, 2 quarts, 1 of Round-leaved and 1 of Prickly-seeded; Early Dutch Turnip, 2 ozs., White Stone Turnip, 2 ozs.; Savoy, and Brussels Sprouts, half an ounce each. Of Enfield Market Cabbage, Green Coleworts, Walcheren, Early Cape, Purple Late Sprouting, and Miller's Dwarf Broccoli—Mammoth Celery, Incomparable Dwarf White Celery—White Cos, Brown Cos, White or Victoria Cabbage, and Hardy Hammersmith Lettuce—and of Endive, there should be half an ounce each. Other salads and herbs in proportion.

This I merely give as a sample of what I should consider as a fair proportion of what seeds would be required for the space and how I should select them; but I do not say that the list should be exactly the same every year, or that I should select more than once in that manner. Far would I be from recommending it as a guide to others; such matters are best left to those who alone have to deal with local circumstances, and who can, or at least should, be the best judges in the matter.

I simply write this in answer to "AN OLD SUBSCRIBER," who expresses interest in my former remarks, and so far I am glad to learn that they have been received with any interest at all; but I am also sorry if they have caused any unpleasantness between the employer and employed. There is such a thing in the world as trying to please all parties and pleasing no one, and when one is pleased another is displeased; but it is very difficult indeed to please all alike. If any dispute should have arisen between this employer and his gardener through what I have said, it is inadvertently on my part when trying to point out what I have found successful. But on the part of gardeners I must say that, although they do not always make the most of the means at their command, those means are more often too limited than otherwise, and that many of them have to work against adverse circumstances until they become tired of it and careless of the results.

There is one part of "AN OLD SUBSCRIBER's" letter which rather surprises me. I have always found that both Sea-kale

and Rhubarb can be grown if not forced as cheaply as, if not cheaper than, they can be bought. In fact, I have found that they will both grow luxuriantly almost anywhere and with little trouble; and if they can be bought cheaper than they can be grown it says very little either for the ground or the management. But stony loam is not the best soil in the world, although, as I said before, any soil may be made productive under proper management.—F. CHITTY.

HEATING HORTICULTURAL BUILDINGS.

(Concluded from page 112.)

HEATING BY FLUES.—I mentioned some few weeks ago that an extensive range of forcing and other houses at Ravensworth Castle, in the county of Durham, was heated by flues which had been in use more than half a century. Doubtless they have been repaired, and, perhaps, altered during that time; still they do their work well, and I do not know whether I should like a change to hot water in such a place, although, as I believe, within a circuit of five miles of the Castle, scores of miles of cast-iron pipes are made every year, and there is rarely a day passes but the sound of boiler-building is heard.

Flues have their advantages, and I am no enemy to flues when well constructed, and when used in such a place as the one I speak of where coals are cheap. The flue is also less liable to accident than hot water, and when a misfortune does happen it is much more easily rectified. Most men could find something to stop a leaky flue, but it requires days and the assistance of practical hands to repair a cracked boiler. I know of no way of renovating a cast-iron boiler but by replacing it with a new one, and this, perhaps, may have to be done at a time when the external thermometer may be 15° or more below the freezing-point. I by no means wish to detract from the merits of hot water—I only desire to give the flue its due; and if both modes of heating had had an equal amount of attention bestowed on their improvement, it is probable that that by means of flues would have arrived at a higher degree of perfection than it has yet attained. Still some advance has been made, and a plan my worthy employer allowed me to adopt here some five or six years ago having answered so well, I will at once describe it.

Having built two half-span-roofed houses, each 36 feet long by about 14 feet wide, and of a proportionate height for greenhouse plants of various kinds not requiring a high temperature, I thought it was needless to incur the expense of a hot-water apparatus, for the houses, being at some distance from the others, could not be heated by the existing means. It was, therefore, determined to try the old flue. The houses in question contained a broad front shelf or platform of about 3 feet wide, and then a path, the remainder being shelves to the back wall, and the doors entering at the ends opposite the path, which went straight through. The mode of heating has nothing unusual about it, for behind the back wall and in the centre where the partition was the fireplaces were dug, and a flue goes round each house. The two fireplaces are low enough to allow the smoke in the first instance to ascend a little. The flue at its commencement is of brickwork with stone covers, and so low that the covers are on a level with the pathway. It gradually rises as it turns under the front shelf, and about 2½ feet of this portion is also brick. The remainder of that under the shelf is cement pipe 12 inches in diameter, until near the farther end where a short length of brick flue descends to the level of the pathway, and the flue of cement pipe returns along the back wall again, finally passing upwards in a chimney over the fireplaces.

Now, there is nothing new in this, excepting the use of cement pipes, and I may safely say they do their duty well. Like every one who has occasion to put a fire into a flue that has long been out of use and is damp, I find a little escape of smoke is sure to ensue; yet, strange to say, such escape has always been from the brick flues and not from the cement pipes. I have not had occasion to clean the flues out yet; but the arrangement of having the slanting covers at the ends to take off readily will render the cleaning-out of the pipe an easy matter.

A less-sized pipe might have been advised by some, but it must be observed the houses are far from being small, and a less pipe would require cleaning-out much more frequently; besides the expense is not a serious matter, and the pipes being about an inch thick or a little more, they heat quickly. They will, it is true, also cool quickly, but this is of much less con-

sequence; for assuming the atmosphere of the house to be at 45° at four in the morning and the fire then to go out, the heated flue and warm atmosphere in the house would hardly suffer a diminution of temperature likely to be hurtful before morning, unless the frost were very severe indeed, or the house indifferently glazed. I may add, that I have never found any such inconvenience.

The pipes are 30 inches long and fit into each other, requiring but very little cement to set them. I believe the best kind of pipes for standing fire to be those made of Portland cement; but we have some made of Roman cement that stand very well. I have been told by the maker that he has had a Portland cement pipe heated by charcoal and over a blast almost to a white heat without any injury being done to it, and such heats are never wanted in flues. As the readers of THE JOURNAL OF HORTICULTURE may wish to know all particulars, I will at once state that the cost of Roman cement pipe of the kind used was, at Maidstone where it is made, 1s. 1d. per foot run. The Portland cement one was, I believe, 1s. 6d. per foot. Both inside and outside they are round, only a flattened surface is added to the bottom for them to rest on. Ours rest on slender brick pillars at the ends, the other part being all above ground, and the appearance being far from unsightly.

HEATING BY HOT WATER.—Although I have had something to do with hot-water heating for about thirty years, I am far from certain which is the best plan yet. Some systems are certainly bad, and have, consequently, fallen into disuse; while others, as, for instance, Perkins', are hardly adapted for horticultural buildings, besides being very expensive; and again, Kewley's plan has so many disadvantages that it cannot be recommended. There is, however, one old plan which I think rather hastily fell to the ground, without that fair trial which might have given it popularity. Unfortunately, the inventor patented his contrivance, which was an open gutter pipe with a moveable covering, which could be taken off either wholly or in part. I think this was Corbett's plan; but the fear of infringing the patent-right prevented, at the time, further improvement, and I think the plan has fallen into oblivion. The principal object of after-inventors has been to contrive a boiler capable of doing more work than any hitherto in use, and boilers of all shapes and forms have been brought before the public. Not the least useful among these was Sampson's spiral boiler, which was over the furnace, but continued in a spiral form round the chimney. The setting was an easy affair. I only mention this boiler as one not generally known.

The other classes of tubular, conical, retort, and saddle boilers have been so often before the reader as to require no explanation here; neither will I undertake to say which is the best, as so much depends on circumstances. I cannot, however, but observe that the old saddle boiler is by no means bad, and of our six boilers two of them are of that kind. The conical form may certainly economise fuel a little more; but it necessitates that fuel being of a particular kind, and is on that account objectionable, but they may be set so as to be heated by a wood fire; or any kind of rubbish that comes to hand may be burnt underneath. They may also often be left without attendance for a very long time with safety, not but that other boilers have equal advantages in this respect. I have known a coil of pipes to form the boiler, and it was said to do its work well; in fact, Perkins' heating apparatus is of this kind; but the one I allude to was much larger than Perkins'.

I am also told the retort is a good boiler, but I have neither seen that nor Messenger's at work: therefore, I can only speak by report. There is little doubt but those tubular boilers of Messrs. Weeks and of Mr. Ormson will heat the quickest; the only fear is, with so much complication of parts some place may give way at some unfortunate time. I would certainly never depend on one boiler alone to work a large space; for it is certain that some day an accident will take place, which may be attended with serious consequences. Two boilers, each contrived so as to connect itself with the series of pipes, would obviate much of the danger there is no doubt; but it might even happen that an accident might occur to a connecting-pipe, and derange the whole. This is certainly not so likely as an accident to the boiler, but it has been known to occur; it is, therefore, better not to have everything depending on one frail connection. One misfortune would do more harm than would pay many times over for the extra fuel used in heating by another apparatus.

Hot water, however, is so very accommodating that I would

by no means disparage it. It is clean, convenient, not likely to get out of order, and so very accommodating that the pipes will mount any reasonable height and descend also, and it is difficult to say how far the hot water will travel. It will circulate through pipes of any kind or size; for I have seen them round, half-round; flat, like a three-inch plank; and edgeways-up, like an inch deal. The last was, perhaps, the most foolish way of any. Generally speaking, four-inch pipes are the most convenient; I have seen some double that size and more, and we have one house here heated by tanks, through which the water circulates freely, and it works well. In fact, it is so difficult to put any limits to what may be done in hot water, that I leave the further following-out of the subject to other hands.

POLMAISE AND OTHER MODES OF SUPPLYING HEAT.—Polmaise was certainly at one time as strongly advocated by its patrons as orchard-houses are now by those similarly disposed to ride a hobby, and doubtless, to a certain extent, both are right. Polmaise has fallen into disuse or nearly so, to be now and then revived, perhaps under another name and with some supposed improvement; nevertheless, when it works well, I do not know of any mode of heating that will beat it for the welfare of the plants. Unfortunately, it is extravagant of fuel, and now and then such awkward misfortunes happen with it that it cannot be called safe. Many years ago Mr. Ogle, at Eridge Castle, tried it and reported upon it, but he has since abandoned it. The only place I have seen it in use of late years is at Sir E. Filmer's, Bart., East Sutton, where a Pine-pit is heated very well with it, and the plants do remarkably well; but Mr. Skinner, the gardener, says it is expensive in firing. There have been many variations of this mode of heating, some of them differing but little from the old-fashioned flue; it is, however, not in general repute at the present day, neither is it likely to be restored to popular favour.

Of the temporary modes of heating pits and small houses with Arnott or brick stoves, I cannot say much. The care required to attend to them is more than can at all times be calculated on from an unwilling servant, but that the enthusiastic cultivator will make them answer I have no doubt; indeed, there is very little but what the really industrious and persevering man can accomplish, and this he will be sure to do. Guarding against unpleasant vapour, and supplying moisture, not to the plants but to the atmosphere, will do much to prevent the evil effects of a mode of heating that ought only to be adopted in cases of emergency.

RELATIVE MERITS OF HOT WATER AND A SMOKE FLUE.—I expect the conclusion that many would come to would be favourable to hot water, but I am far from certain that its adoption is prudent in all cases. Certainly there are none in which it will not answer as well as the flue, but then it is much more expensive; and when the heat wanted does not, perhaps, exceed 40°, an expensive heating contrivance ought to be avoided. For such structures I would, therefore, advise a flue; but where anything like forcing is wanted, with a fire every day, perhaps, for six months or more, then have hot water. It will pay to have it in the latter case, although not in the former, for reasons that will be obvious to every one. There are also some other reasons which, in some cases, may operate one way or the other: thus the expense of firing is an item that may determine the kind of heating, for where fuel is expensive the most economical mode of using it, even if such apparatus be costly, will be the most prudent to adopt. Where firing is cheap another view of the matter may be taken. To illustrate this, I will mention the two extreme prices I have paid for coals. The lowest was 1s. per ton, and the highest 42s. Now, it required very little reasoning to show that an expensive apparatus to lessen the quantity of coals wanted in the one case might be advantageously entered into; while in the other, where the coals were cheap, it would be an unnecessary expenditure unless accompanied by other advantages. More than this need hardly be said, nevertheless I may again return to the subject.

J. ROBSON.

ORCHIDACEOUS PLANTS.

The third Part of "Select Orchidaceous Plants" by Messrs. Warner & Williams is fully worthy of its two predecessors, which is praise sufficient. It contains *Epidendrum prismatocarpum*, rare, pretty, and fragrant; *Lycaete Skinneri*, the most useful winter Orchid we possess; *Aerides nobile*, "one of the

most beautiful of its family;" and *Lælia Turneri*, "one of the finest plants known among Orchids." The coloured portraits of these are exquisite, and combined with the botanical descriptions and abundant practical notes, will render it eventually one of the most complete works upon Orchids hitherto published.

GASTROLOBIIUM CALYGINUM (LARGE-CALYXED GASTROLOBIIUM.)

Nat. ord., Papilionaceæ. *Linn.*, Decandria Monogynia.—A showy greenhouse shrub, of considerable value as an ornamental plant. The branches are smooth; the leaves are opposite (or ternate), elliptic, somewhat keeled, glaucous, and terminated by a long pungent awn; at their base is a pair of spreading decurved spiny stipules. The flowers grow oppositely in terminal or axillary racemes, and are very large; the standard deep orange with a yellow spot at the base margined with crimson; the wings and standard deep crimson; they grow from the axil of a large, obovate, membranous, inflated, strongly-nerved bract, the nerve being extended into a recurved mucro; the calyx is very large, the upper lip much largest, bifid with very obtuse segments, the segments of the lower lip ovate acute. The ovary is villose and distinctly stalked.

This interesting plant was raised by Messrs. Henderson, from Mr. Drummond's Swan-River seeds.—(*Gard. Mag. of Botany.*)

NEW VEGETABLES.

A YEAR or more ago seeds of one or two Chinese vegetables were disseminated through the medium of the Horticultural Society, or some other public body, one of the packages reaching the writer; but through some accident or mismanagement, I did not get any to grow. Perhaps some other of your readers may have been more fortunate, and if so, it would confer a favour on the community if the result were recorded.

The names given to me were so indistinctly written, and seemed intended for a word so uncouth and unpronounceable, that I cannot repeat them. The seeds were about the size of those of Cucumbers.

That the Celestial Empire contains vegetables that might be turned to useful account amongst us there is no doubt; and though our palates may have become too much habituated to the use of those we now have to easily accommodate themselves to the production of another country, the younger members of the community could easily accustom themselves to the new article, if it came before them in an agreeable and acceptable form. I therefore thus publicly ask, through the medium of your Journal, if any one has reared the new vegetables, and what is their opinion on their merits?—AN OLD SUBSCRIBER.

TO THE EDITORS OF THE JOURNAL OF HORTICULTURE,

AND THE MANY KIND FRIENDS, WHO, HAVING SYMPATHISING HEARTS, HAVE CONTRIBUTED SO LIBERALLY TOWARDS RELIEVING US IN OUR GREAT DISTRESS.

KIND LADIES AND GENTLEMEN,—We, the undersigned Lancashire botanists, having received much through your kindness and sympathy in this our hour of suffering, now return our heartfelt thanks. Many of us were suffering most acutely both for food and clothing, when our kind friend, Mr. John Hague, appealed to your Christian sympathies on our behalf—an appeal which has scarcely ever been made in vain on behalf of wretchedness and distress. In our case we feel more deeply the kindness of those friends at a distance who, though entire strangers, yet could feel for us more than the common sympathy of humanity, shown by a response that has both surprised and gladdened the hearts of the recipients, and filled them with thankfulness and gratitude, not only to the generous donors but to that kind Providence who has raised up such kind friends in this our time of need. Some of us were reduced almost to the last stage of destitution, because we could not become the recipients of parish allowance to be treated like common paupers, no distinction being made by the parish officials; neither could we stoop to beg, our only desire being to earn our bread by honest daily toil, which is the greatest sweetener to our cup through life. This was the reason why some of us were suffering, when our kind friend, Mr. Hague, made his appeal, and for your noble response we beg to tender our sincere thanks and heartfelt gratitude.

Also, to you gentlemen, the Editors of THE JOURNAL OF HORTICULTURE AND COTTAGE GARDENER.

And may the Giver of all good return you an hundred-fold for what you have lent Him; and may He add His blessing free from sorrow, and preserve you all in the enjoyment of health and happiness to a ripened age, is the sincere prayer of your most obedient humble servants,

Rodger Schofield, John Whitehead, Titus Broadly, Henry Collins, Joseph Harrop, Thomas Horrocks, John Dingham, William Kelsall, Joseph Longden, Mark Dean, Henry Newton, Joseph Beech, John Newton, John Oldham, James Pickering, James Smith, Robert Gordon, Charles Whitehead, John Roberts, John Taft, Edwin Chough, James Kirk Smith, Richard Bird, Edward Richardson, Uriah Kay, Lee Foden, Mrs. Howard, Frederic Schofield, William Parkinson, Samuel Moss, John Hulme, Nancy Smith, Jethro Ferns, James North, Henry Cropper, George Hokhouse, Luke Wild, Jethro Tinker, Ann Lees, Thomas Andrew, Mrs. James Parkinson, Daniel Hayden, Thomas Cheetham, Edward Lees, Thomas

Broadbent, William Middleton, John Kinder, Michael Ward, John Moss, James Smith, John Johnson, Thomas Birchall, James Stafford, William Scott, Benjamin Platt, Ebenezer Platt, John Middleton, Samuel Beard, James Platt, Daniel Platt, Charles Haigh.

SINCE I last wrote I have sold plants, &c., sent for the purpose of giving aid to the distressed botanists, to the amount of £3 16s., and have received from Mr. P. McCulloch, gardener to Sir A. A. Hood, Bart., M.P., Audries, Bridgewater, Somerset, 16s., collected from the men under him. I have been able to help eight botanists and their families in the neighbourhood of Broadbottom and Mottram, about six miles from here, whose destitution I only heard of three weeks ago. I wrote to the relieving officer of the district, and he gave me some valuable information about their distress. The principal mill in that district had been stopped thirteen months, and most of the persons I gave help to worked at it, and they were wretchedly off. There are eight more persons than the above who have received assistance.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

CEREUS PTEROGONUS (Wing-angled Cereus).—*Nat. ord.*, Cactaceæ. *Linn.*, Icosandria Monogynia.—Native of Carthage, South America. Flowers white, blooming in August.—(*Botanical Magazine*, t. 5360.)

PHÆDRANASSA OBTUSA (Blunt Phædranassa).—*Nat. ord.*, Amaryllidaceæ. *Linn.*, Hexandria Monogynia.—Called also Phycelia obtusa. Native of Pichinca Mountain, near Quito, more than 10,000 feet high. Flowers scarlet, tipped with greenish-yellow. Blooming in winter.—(*Ibid.*, t. 5361.)

CYPRIPEDIUM HOOKERÆ (Lady Hooker's Cypripedium).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Diandria.—Imported by Messrs. Low & Sons, Clapton Nursery, from Borneo. Leaves variegated, dark green, with pale mottling. Flowers variously marked with yellow and purple on a pale green ground.—(*Ibid.*, t. 5362.)

PLUMBAGO ROSEA var. COCCINEA (Scarlet Rose Leadwort).—*Nat. ord.*, Plumbaginaceæ. *Linn.*, Pentandria Monogynia.—It has also been called *Thalia coccinea*. Messrs. Veitch & Sons, Exeter and Chelsea Nurseries, received seeds of it from the Neigherry Hills. Flowers brick red, in panicles.—(*Ibid.*, t. 5363.)

CINCHONA OFFICINALIS (La Condamine's Peruvian Bark).—*Nat. ord.*, Rubiaceæ. *Linn.*, Pentandria Monogynia.—Native of Ecuador Mountains. Flowers pink.—(*Ibid.*, t. 5364.)

FUCHSIAS.—*Sanspareil*, crimson tube and sepals, corolla white. *Hercules*, tube and sepals crimson, corolla double and deep purple-coloured. Raised by Mr. G. Smith, Tollington Nursery, Hornsey Road. Very beautiful.—(*Floral Magazine*, pl. 133.)

PELARGONIUMS.—*Monitor*, a large dark flower, deep shaded rose, with large black spot on each petal. Had first-class certificate. *Queen of Whites*, lower petals silvery white, upper petals carmine, with narrow white border. Had a first-class certificate. Both raised by Mr. Dobson.—(*Ibid.*, pl. 134.)

POMPON CHRYSANTHEMUMS.—*Fairest of the Fair*, florets lilac bluish with silvery tips. Raised by Mr. Salter. *Mary Lind*, upper side of florets lilac bluish, under side purplish. *Julia Engelbach*, golden, with brown points. These two were raised by Mr. Smith.—(*Ibid.*, pl. 135.)

HYBRID ACHIMENES.—*Carminata elegans*, spikes very large; flowers deep crimson. Raised by Mr. Parsons, of Danesbury, near Welwyn.—(*Ibid.*, pl. 136.)

PELARGONIUMS.—*Regina formosa* (Beck), rose-coloured. *Conflagration* (Foster), crimson red. *Royal Albert* (Hoyle), carmine rose. *Belle of the Ball* (Foster), sub-spotted rose. *Royalty* (Foster), very distinct rosy carmine.—(*Florist and Pomologist*.)

GROSSE CALEBASSE PEAR.—Seedling of Van Mons. Flesh crisp, juicy, sweet, but without much aroma. It is a very large variety.—(*Ibid.*)

METEOROLOGICAL OBSERVATIONS IN 1862.

Total

The average of the two preceding years.

The receiving surface of gauge is 8 inches from ground.

* The average of the ten preceding years.

+ The receiving surface of gauge is 8 inches from ground.

With the exception of the first three months the year was cold and wet, and decidedly ungenial to many flowers, fruits, and vegetables under the gardener's care. Although the harvest of the country at large was equal or nearly so to the average, and housed in fair condition, yet in this locality cereals were late in ripening, and when ripe the difficulty was to know when to cut the crops; for none being ready for cutting before October, and some not even then, a period of heavy rains, set in—not showers, but days of deluging heavy rain, which not only hindered harvest operations, but prevented late crops on wet lands from ripening.

On the 11th of October 0.61 of rain fell, 0.34 on the 12th, 0.65 on the 15th, 0.32 on the 16th, 0.38 on 18th, 0.32 on 19th, 0.61 on 20th, with hail and high wind, 0.71 on 21st, 0.36 on 22nd, accompanied by thunder, 1.06 on 23rd, followed by showers on the next two days; then 0.64 of rain and hail on 26th, 1.14 on 27th, and showers on the following day, succeeded by fog, which cleared away in the first frost on the 30th (27°). October was the wettest of any corresponding month during the last thirteen years, judging according to recorded observations; but according to those whose opinions were derived from experience it was the wettest October ever known. Though doleful be the tidings the worst is not yet told. Fields of Oats were standing in shock on the 10th and 11th of November, when the ground was covered with snow 3 inches thick. There was corn out on the 1st of December.

I have to note Turnips were small, Mangolds no crop, but Potatoes were good and free from disease. Herbage was abundant. Rye-grass, of which no inconsiderable quantity is needed, was good, and furnished three cuttings; Pacey's Perennial affording the best supply, and it is not so coarse as some varieties. Cutting grass on meadows was general in the beginning of July, but up to the 12th little was made into hay; when, finer weather setting in, the greater quantity was stacked in moderate condition.

A backward and wet spring hindered garden operations, but it was not worse than in the two preceding years. Owing to wetness of the soil seeds vegetated badly, and in many cases there was a total failure, entailing a second sowing.

The bloom on fruit trees was abundant and set well. There was an abundant crop of Gooseberries, but caterpillars threatened to annihilate them completely; so numerous were they that they infested the Ribes species in plantations. Of Currants, Red and White, the crop was good; of Black moderate. Raspberries were abundant and large, but insipid owing to the wet. Strawberries were a good crop, but maggot and canker made large gaps in the plantations. Apples were plentiful but small, and did not ripen properly; consequently they shrivelled more than usual, and proved flavourless; Pears a moderate crop; and the same may be said of Plums. Cherries proved to be a very fair crop, but nothing according to the promise of bloom. Peaches did not ripen on walls, and the crop was small. To the above it may perhaps be added that Grapes were much given to shank, poor in flavour, and very deficient in colour; notwithstanding this some admirable specimens were exhibited at the Bradford Show, and did great credit to the exhibitors. Melons were worthless in unlined pits and frames, and deficient in flavour under the most favourable circumstances.

Orchard-houses were a dead failure, and have been in this locality ever since their introduction; but I have to note that three beautiful specimens of Peach trees, in 11-inch pots, were exhibited by Mr. Comfort, gardener to J. Priestman, Esq., of Wheatley Hill, each tree averaging two dozen fruit, some of them measuring 8 inches in circumference. Also by their side was a Sweetwater Vine in a 12-inch pot, carrying eight bunches (if memory be a safe guide) of medium size and with good-sized berries; and a Fig tree, in an 11-inch pot, full of fruit of the best of all Figs—the Brown Turkey. Thus it would appear some succeed while others fail, and we have to confess we are one of the latter.

Carrots were a bad crop, and maggot-eaten. Onions no crop. Beet small—too small, but more than usual of top. Salsify and Scorzonera medium-sized and good in quality. Shallots much grown by cottagers, fair crop. Potatoes, earlies, poor crop; main crops good. Had a packet of the substitute for the Potato, Charophyllum bulbosum, from the Royal Horticultural Society; but it produced nothing like so good a substitute as a Carrot. The Ground-nut (*Bunium denudatum*) would be as good a substitute for the Potato as it.

Peas were a fair crop, running to haulm. The best we had

were Noble's Early Green Marrow, Dickson's Favourite, Veitch's Perfection, British Queen, and Sangster's No. 1—the favourite of your respected correspondent, "D., Deal." Though differing with him in taste, I would advise his sowing his favourite Sangster's No. 1 and the Warwick race at intervals of ten days or a fortnight, according to the supply needed, giving the sowings after April a manured trench as for Celery, and a good soaking of water once or twice a-week according to the state of the weather. Early Peas cannot stand drought; and unless the land is heavy or copious watering resorted to, they are only like so many pea-bullets.

Of Dwarf Kidney Beans and Scarlet Runners I never had a dish. Cauliflowers were late but good. Broccoli doing well. Borecole and the whole tribe of Coleworts have done pretty well, but the wet has made them very seedy-looking. Cabbages have been fearfully maggot-eaten at the root, in consequence of which many a healthy-looking plant withered when sun appeared, though that was seldom; others have clubbed instead of hearting. Celery was bad with us, but good in some places. The best I saw was growing in clay nearly as pure as brickmakers have it. Maggot attacked some (dry soot sprinkled on wet leaves will drive it away), but as to the maggot being the cause of failure I beg to demur. Celery, like the potato, is rendered so liable to disease by high cultivation, as to be little more than gorged and swelled out of health into disease.

Spinach leaves were a receptacle for the eggs of the white Butterfly, and the Winter one was there as well.

Lettuce and snails had a terrible struggle for life, but young Ducks scooped the slugs up; yet web-footed bipeds cannot be tolerated in gardens long, for no thunder-storm soddens the soil like them; and as for bantams and the whole tribe of hens, they are too much given to scratch, and they eat too much green food for my fancy.

Bedding plants cut a sorry figure; and, taking them altogether, for me there is nothing like the good old herbaceous border full of bloom in spring, delicious with Pinks and Carnations, and fragrant with Roses. Sure of a nosegay all the year round are those who tolerate flowering shrubs, bog plants, alpenes, and aquatics; besides, in geometrical gardens, handsome and brilliant as they may be in summer, interesting in winter with evergreens, and pretty in spring with bulbs, those mixtures are more frequently failures than successes.

Notwithstanding the adverse season we had a good exhibition here (Bradford). Plants were good. Mr. May, Bedale, had first-class Hollyhocks and Dahlias, the last somewhat hollow in centre; and Mr. Edwards, York, was a close competitor. The Carnations and Picotees at the National were superb. Messrs. Steward & Wood, of York, and Holland & Bayley, of Manchester, were the lions. However, horticultural exhibitions are not places to judge the seasons at, for there we have the choice-selected, but away from them we have generalities.

Three indifferent years succeeding each other must tell their tale on our trees from warmer climes, which I fear is too manifest; for Peach trees threaten to become evergreens, and many others have a like tendency.

We have a doleful beginning for a new year; rain and wind daily, and the ground like a sponge, do not augur well of 1863. —GEORGE ABBEY.

WORK FOR THE WEEK.

KITCHEN GARDEN.

WHILE our climate maintains its variable character the necessity of conforming to its dictates in all gardening operations will exist. The continuance of fair weather will permit the operations that peculiarly belong to this month to be proceeded with. *Asparagus*, in mild weather that in frames or pits should have abundance of air after the shoots have made their appearance. Prepare ground for permanent beds; if the soil works well, to be trenched 2 feet deep at least, and plenty of good rotten stable manure incorporated with it during the operation. Mark off the beds 4 feet wide, and 2 feet for the alley, then mark the rows on the bed one in the centre and one at each side; lay a ridge of maiden loam, leaf mould, and sand, of equal parts, along where each row is to be planted, and on these ridges place the plants. They may be either one or two years old, but not more than two, the plants to be taken up with great care. When placed on the ridges, with an equal portion of roots on each side, cover them to the depth of 2 inches with pure sand if it can be procured, which will induce the plants to throw out

numerous young roots, which, passing through the sand, seize with avidity on the more nutritious compost prepared for them. Above the sand add 3 or 4 inches of loamy soil over the crowns; and should the season prove dry, mulch between the rows, and give occasionally waterings of liquid manure. *Onions*, plant the bulbs of last year which begin to grow, they will be found useful where there is a scarcity of sound ones. They may also be planted for seed. Plant the underground sort, if not done in the autumn. Weed and clean the autumn-sown. *Parsley*, a sowing to be made where the ground is in a fit state to receive the seed. *Peas*, make a sowing of Knight's Dwarf Marrow; at the same time some other approved sorts should be sown to keep up a succession. Sow also two or three sorts which come in for use quickly, as they will be fit to gather before the Marrows. All vacant ground to be dug as quickly as possible, so that it may be ready for cropping.

FLOWER GARDEN.

The weather calls upon us to expedite all retarded operations, particularly pruning. Turf may be cut and laid, and wood ashes spread on lawns where the grass is injured by moss. When the natural soil is not favourable for *Rhododendrons*, *Belgian Azaleas*, &c., an artificial mould may be gradually formed by sweeping the fallen leaves over the roots and covering them with sand every season. Prune and tie climbing plants. Prune *Roses*, unless they are wanted to flower late. Herbaceous perennials should be planted as early as convenient. Sweep and roll the lawn and walks. Where it may be necessary to increase the stock of any of the varieties of *Dahlias*, these should be placed in heat at once in order to secure cuttings. Look to *Crocus* bulbs, &c., planted in beds, and protect them from the depredations of sparrows and mice.

FRUIT GARDEN.

Prune *Raspberries*. Any *Gooseberries* or *Currants* not previously pruned should forthwith be attended to. Collect fir boughs to protect the blossom of Peach and Apricot trees. *Gooseberry* and *Currant* bushes occupy much less space in a garden trained to stakes, and afford an equal if not greater amount of fruit. Proceed with planting fruit trees where circumstances prevented its being done in the autumn.

STOVE.

Any specimen plants in this house which require shifting must be attended to in the course of the month. *Stanhopeas* and *Oncidiums* with other Orchids may be potted. Temperature 55° to 65° with a moist heat, and increase a degree or two every week for the next month. Shut up early.

GREENHOUSE AND CONSERVATORY.

The admission of air on all favourable occasions will conduce to the health and keep the various flowering-plants in unimpaired beauty for some weeks. *Hyacinths*, *Lilacs*, *Roses*, *Kalmias*, and *Azaleas* introduced will lend beauty and fragrance to the various groups. The rich yellow flowers of *Cytisus racemosus* will add in no slight degree to the general effect. The early-flowering plants of *Camellias* now returned from the conservatory or mixed greenhouse, should be placed in heat in order to be encouraged to make a vigorous and kindly growth, and to set their flower-buds in due season. Look carefully over the early-blooming plants—such as *Heaths*, *Azaleas*, and *Boronias*, and see that they are not getting too forward. There is less difficulty in keeping them back at the present time than when we have bright sunny days. Sow exotic and other seeds generally during the present and following month. As the principle of hybridisation is beginning to be understood and generally practised, doubtless additional interest will be discovered, and attention bestowed on the propagation of plants by seeds. Shift and tie-out *Pelargoniums* as may be required, and allow them plenty of space after this time, with all the light possible, and a free circulation of air whenever the weather will permit. Do not allow *Calceolarias* to suffer for want of pot-room, as any check at the present season might throw them prematurely into bloom. *Cinerarias* and other plants will require frequent shifting and placing at greater distances from each other, in order that air may be permitted to circulate freely among them.

FORGING-FIT.

Here a good stock of *Roses*, *Azaleas*, *Lilacs*, &c., should be coming into bloom. Take care to keep up a regular succession, and fumigate occasionally to keep all clean.

PITS AND FRAMES.

Give air freely to plants such as *Verbenas* and *Calceolarias*, and

carefully remove all decaying leaves. A batch of *Amaryllis* bulbs should now be shaken out and repotted in half-decayed turfy loam, mixed with a small portion of sand and a pretty liberal supply of charcoal. Remove to a warmer place any of the plants from which cuttings are required. Alpines and other rare plants in pots should now be looked over, remove all decayed matter, and stir up the surface of the soil. Those which it may be desirable to propagate should be divided into pieces, repotted, and placed again in the frame. W. KEANE.

DOINGS OF THE LAST WEEK.

In the kitchen garden the routine was much the same as last week, with the exception of choosing a dry day to plant some Potatoes of the Early Ashleaf in the open air on a ridged bank, planting only the south side. This had been ridged-up about 24 inches apart, and the sets, just sprung, were set in the furrows, and the nice, dry, aired earth of the ridge was trundled over them, after a slight sprinkling of lime. The sets were sprung an inch or so before planting. Turned out also into a bed over heated tree leaves, the same kind, plants 3 or 4 inches in height, in rows, 6 inches apart in the rows, and about 18 inches from row to row. The soil put over the leaves was about 6 inches deep, then the Potatoes were set on the level, the small roots carefully covered, and then covered with about 5 inches on the flat. These will have the earth raised to the stems 2 or 3 inches as they grow, which admits of the sun's rays passing up between the rows, and we think that from this mode the produce is rather better than when the soil is left on the level. For such work we have met with nothing to beat the true Ashleaf. The Handsworth and some others may come a few days earlier, but we do not find they are prized at table like an Ashleaf. This, however, may be a mere matter of taste, or even of prejudice, just as in the case of the watery white Turnip, because whiteness will be insisted on. For flavour, several of the yellows are, in our opinion, far superior; and for flavour and nourishment combined, commend us to a good Globe Swede that has lain in an open shed a week before cooking. If that is cut up, boiled thoroughly—and an hour at least will be required—if in liquor in which pork or other meat was boiled first all the better, and if a slice of the meat can be had with it, then there is at once a feast for a hungry prince as well as a hungry ploughman.

A gentleman lately told us that he quite envied the zest and relish with which the ploughboy standing by his horses, pitched in wedge after wedge of half-boiled pork and dry bread, stating his belief, and we are certain with much truth, that that boy had more gratification in thus eating to satisfy the demands of his appetite than he himself had in partaking of the finest made dishes, because he did so more as a matter of form than from any natural desire or want. It has been wisely ordered that there should be pleasure in eating; but that pleasure will be greatly dependant upon our working for it and the natural craving for it. Here, as in many other cases, the rich man and the hard-working man are placed more equally as to the means of happiness and true enjoyment than is generally imagined. The farmer, then, who wishes to kindly help his labourers, may, without any misgiving, allow them a few of his best Swede Turnips, and tell them how to cook them, which when well prepared will be almost as solid as cheese.

The Potatoes in the bed alluded to above will be our second crop, as those grown in pots, as previously mentioned, are tubering nicely. Some time ago we mentioned having some litter to throw over Radishes out of doors, sown in autumn, except there should be a sudden frost. These will naturally, and especially in such a winter as this, become hard, and we suppose must have sent them in once or twice too often, for a week ago we were mortified to see a fine plate of early Radishes from a frame, as crisp as possible, come out untasted. If a fortnight or three weeks had intervened between the old and the new, somebody would have found out the difference.

This simple matter of the Radishes may well furnish a lesson of sound policy. Some people will say, "I had such abundance of such and such good things, as thoroughly to sicken and tire me of them." Now, the great point is, to have sufficient without superfluity. Whenever superfluity is presented, the feeling of satiety displaces that of pleasure. Of course, in large places, where fine things must be had constantly, our duty is to produce them, and not think of the enjoyment. There can be no question that the very frequency, the uninterrupted supply of a certain

dish, will lessen the pleasure of partaking of it. The gentleman who tastes the first Cucumber of the season in April, and the same as respects Kidney Beans and Potatoes, will relish them more than the other gentleman who has them at his table every day all the winter. The satisfaction of the latter will spring less from selfish gratification than from the pleasure of presenting rarities for the enjoyment of his guests.

FRUIT GARDEN.

In addition to pruning, nailing, &c., unailing Peaches against walls, &c., damping vineries in hot days, and giving plenty of air to Peach trees opening their buds, the chief work has just been moving Strawberry-pots from vineries into a Peach-house, not because they will have more heat, but because in this dull weather they will have more light; and secondly, examining the buds and washing-off any black beetles or fly that made their appearance on the Peach trees coming into bloom. We never met with this ugly gentleman until last season, as fully described in a previous volume, and here he is again making his appearance here and there, notwithstanding all our care. We will, for the sake of others, repeat what was done. In November this house was smoked with sulphur and sawdust, killing, of course, every leaf that remained green, and, as we thought, every vestige of insect. Then, to make surer, in a few days the house was thoroughly syringed—trees, walls, and woodwork—with water at about 180°. After that the whole house, trees, walls, &c., were scrubbed with soap water; 2 inches of the surface soil of the house was then removed, and afterwards the walls were fresh washed with lime, and the trees painted with clay, sulphur, and Gishurst; and now the gentlemen are coming to tell us that they are not quite done for yet. It is true the house has been filled with bedding plants, which are now being taken out, but nothing whatever appears on them. We much fear they burrow, and lay their eggs pretty deep in the soil. Green fly is bad enough, but a mere trifle in comparison to this dark negro devastation. We see no remedy except hunting-up and destroying every one that appears. For many years one smoking for a Peach-house used to be about sufficient, or if repeated it was more for Strawberries, &c., than for Peaches. We are keeping the trees in orchard-house as cool as possible. We suspect that, from some young tree there, we imported this black fly.

ORNAMENTAL DEPARTMENT.

Those who grow *Gardenias*, *Rondeletias*, *Ixoras*, &c., should now put them into bottom heat. Cuttings should be put in of *Poinsettias* and *Euphorbia jacquiniæflora*, and in a week or two some of the old plants, if helped with bottom heat, will bloom earlier in the autumn, because they will have the end of summer to rest in. Orchids beginning to push should now be watered, and those in baskets dipped in water at about 75°. A higher temperature during the day may be maintained if the sun is at all bright, letting such stove-houses descend to from 60° to 65° at night. Small greenhouse plants may be shifted as wanted into pots a size larger; but larger shifts for specimens should not be given until the sun has gained more power—say the beginning and the middle of March—as such natural excitement is much better than that from any artificial heat. Proceeded with cuttings and potting as last week. We are sorry that the paragraph about *Verbena*-cuttings reads so confused; very likely more the result of careless writing than the fault of the printer. We would like to correct two things: first, the cuttings of *Verbenas*, alluded to at page 121, were not put in tiles three to 10 inches, but three in 2 inches. Then, a little farther down, beginning at the word "Keep," read as follows: "Keep the rough riddlings, mix them with an equal quantity of rough decayed leaf mould, and place that mixture on the top of the rotten dung, to the depth of 1½ or 2 inches." Make that level, and beat it slightly, and then cover this with the fine soil, &c.; and continue the same as given page 121. This will make all clear to "ONE WHO IS PUZZLED," at least we think so. The appearance of the cuttings just says we had better have delayed a little longer, as if we have a cold spring we shall have to try all methods to find room for them and other things.—R. F.

TRADE CATALOGUES RECEIVED.

Barr & Sugden, King Street, Covent Garden.—*Illustrated Guide to the Flower Garden, and Descriptive Seed List*. 1863.

E. G. Henderson & Son, Wellington Road, St. John's Wood.

N.W.—*Catalogue of Flower Seeds, and Select List of Agricultural and Vegetable Seeds*. 1863.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

DO OUR SOILS DECREASE IN FERTILITY? (*W. W. S.*).—We have shown your letter to "J.," and the following is an extract from his reply:—"I wrote anonymously my statements are no more justly charged with irreverence (!) and great presumption than the statements in the *Times* to which they are a reply, and which were also anonymous. If 'W. W. S.' will refer to 'Thomson's Vegetable Chemistry,' he will find that the saps of many plants have been analysed, but apotheme was never found in any one."

CLIPPING LAWN-FRUIT TREES (*J. Smith*).—You cannot be serious. No sane gardener would order his subordinates to "prune wall trees, such as Peaches and Cherries, with the garden shears."

PREVENTING GOOSEBERRY CATERPILLARS (*A New Subscriber*).—Try covering the entire surface of the soil with spent tanner's bark 2 inches deep. Do any of our readers know the effect of this or any other mode of prevention?

EAST WALL (*Mrs. C.*).—Situated at Sidmouth, and the wall only 6 feet high, you might grow against it Apricots, Peaches, and Nectarines; but, as profit is an object with you, we should prefer Morello Cherries. They rarely fail in producing a good crop, and realise a fair price and ready sale. Against the east end of your cottage you may have a Marie Louise Pear.

LIME WATER (*R. G. S.*).—For killing worms, a peck of lime to forty gallons of water are the proper proportions.

COLOURING A GARDEN WALL BLACK (*Emicus*).—We once coloured a wall a sort of slate colour, or rather a lead colour, by a mixture of ordinary whitewash and lamp black, to which a little yellow ochre was added to give it a more cheerful tint. We have also given some wooden and iron work a tolerably good chocolate colour by an admixture of yellow ochre and coal tar. The latter, we know, makes a good black alone; but unless black is especially wanted there are many objections to its use. For it fades fast on being exposed to hot sun, and if some dark grey or slate colour would do, the above mixture might answer your purpose. Of course an oil paint would be better, but will be much more expensive.

PEACH-HOUSE TREES IN BLOSSOM (*A Young Gardener*).—We fear, if you have been giving your trees "five or six waterpots full of water each twice a day," that the roots must be completely soddened. If so, for the future merely damp the paths and all the other parts of the house frequently while the trees are in bloom; and when they begin to grow, and the ground is a little drier, another good watering may be given, using rain water at all times. If your heating apparatus is a fine, occasionally wetting it will be of service; but too much moisture at this time is hurtful.

VINES IN A GREENHOUSE (*E. T. B.*).—As your house is a span-roofed one, and the Vines planted at one end, it would be easier to stretch the wires crossways to the lights, and if about a foot apart and somewhat less than that from the glass (not so far from the rafter, of course), by this means the rod might be pruned spur fashion, and itself occupying one wire, its side shoots which bear the fruit might occupy the wires adjoining on each side. You must not, however, occupy the whole roof with the Grape Vines or your plants underneath will suffer. We have trained Grape Vines in all directions, and have had them planted inside against the back wall and trained down the rafter. If the root be right, the top will bear almost any amount of distortion without injury.

PLANTS FOR CONSERVATORY PILLARS (*G. H.*).—Somewhat herbaceous in character—*Cobaea scandens*, *Eccecarpus scaber*, *Lophospermum scandens*, *Rhodochiton volubile*, *Maurandya Barclayana*, *Maurandya antirrhiniflora*. More shrubby, but strong—*Passiflora cœrulea*, *Passiflora racemosa*, *Bignonia Chirere*, *Bignonia jasminoides*, *Kennedy Marryatæ*, *Jasminum volubile*. Grapes—Lady Downe's, West's St. Peters; the first best where there is little heat.

PAINT FOR GLASS AS A SHADE (*Idem*).—Milk and whiting will make a good shade; perhaps a better is the following:—Heat a quart of jelly size near to boiling, add half a quarter or gill of turpentine, and the same of oil, and the size of a walnut of whiting reduced to powder; mix well. Choose a sunny day, and put on with a brush while the material is hot, as thinly as possible; follow with a dry brush and daub, and it will resemble ground glass.

COVENT GARDEN STOCKS (*E. B.*).—The market-gardeners' variety of scarlet intermediate Stock, if sown now, will bloom in July; if sown in autumn they bloom early in the summer following. The drawing and description you obligingly offer will be very acceptable if both are of the requisite standard.

GLOXINIAS IN THUMB-POTS (*Nora*).—We suspect these little pots are now full of roots. Shift the plants into 60's, and in five weeks shift again into 48's or 32's, giving the plants rich light soil, and a temperature of from 60° to 65°.

COCOA-NUT FIBRE DUST (*Charlotte Faulkner*).—For Ferns and other potted plants, by measure one-third of the dust to two-thirds of loam is a good proportion. To mix with the soil of your flower-borders put it one inch thick on the surface, and fork it in. If the soil is clayey twice that quantity will not be too much.

JASMINUM GRANDIFLORUM (*Sileia*).—This *Jasminum* would do for the rafter of your greenhouse if the roots and stems out of doors were protected. The best plan would be to have a small three-sided box with a top against the wall, and the stem surrounded with sawdust. Seeds would need to be protected from bantams until they were up, and after that, so far as we have seen, the bantams would do little harm.

ORCHIDS IN A CONSERVATORY (*J. E. S.*).—Every Orchid except hardy ones and those from the very warmest tropical positions may be grown in a heat of 65°. The tradesmen who advertise in our columns will give you the price in their priced lists, keeping in mind that the cheapest plants may be the dearest, as almost everything will depend on size. For a small house the following would be likely to suit you:—*In Pots*.—*Ærides odoratum*, *roseum*; *Angraecum caudatum*; *Catasetum cristatum*; *Cattleya crispata*, *Lodigesi*, *Mossiae*, *labiata*; *Cymbidium aloefolium*; *Dendrobium nobile*; *calceolaria*, *moniliforme*, *Farmeri*; *Epidendrum macrochilum*; *Miltonia speciosa*; *Odontoglossum grande*; *Oncidium flexuosum*, *papilio*; *Saccolabium Blumei*; *Zygopetalon crinitum*, *Mackayl.* *Baskets*.—*Cymbidium Devonianum*; *Dendrobium Fierardi*, *macranthum*, *pulchellum*; *Gongora atropurpurea*; *Stanhopea insignis*, *Devonensis*, *tigrina*, *oculata*. *On Blocks*.—*Lælia acuminata*; *Cattleya citrina*; *Oncidium pulchellum*; *Sophranitis grandiflora*; *Oncidium ciliatum*, &c.

HEATING BY A FLUE (*Inquisitor*).—Having flues, in one case round the house, and in the other round the front and ends, we cannot see what you want with stoves in the house besides, if the flues are sound and draw well, as with them any necessary heat could be obtained, and the dryness counteracted by evaporating-pans. However, if you wish a brick stove in the house the matter is simple enough, and any bricklayer would put one up from the description given at the page you allude to in "Greenhouses for the Many." Sections are also given in *Rivers' "Orchard-House."* If you wanted a great deal of heat we would make it 30 inches square outside measure, and $2\frac{1}{2}$ feet in height, and cover with an iron plate, and a course of tiles above, with an evaporating-trough on the top. The stove may stand against the back wall, or a little distance from it; but one secret of success is the shortness of the horizontal pipe that takes the smoke, &c., to an upright pipe outside. It should not be more than 2 or 3 feet, though we have had them longer; but it is best to err on the side of shortness. The other secret is to have a block in front of the smoke-opening, and several inches—say 2 or 3 inches—from it, so that the heat shall be thrown back on the sides and the fire, instead of passing too easily out; or you may have a small damper, either inside or outside, to regulate draught, and to give only a small egress for smoke and heated air after the fire is established. It would be the easiest plan for you to make the back wall of the house the back of the stove, and the asphalt and fuel doors inside; and then you would need to make only one hole for the smoke-pipe, which should be from 5 to 6 inches in diameter. Without a little care you may have dust and a little smoke at times, but very little if due care is taken, and nice dry fuel used for lighting. If these, however, are objectionable you could have these necessary openings behind the wall, but at the expense of more trouble and labour. We look upon the Arnott brick stove as the most economical of all modes for heating single houses, especially where no extraordinary heat is required from them. They are just so much better than iron that they heat and cool more slowly, and there is little danger of the air being burned.

SMALL BIRDS AND GOOSEBERRY BUDS (* *).—You have conferred a boon on the amateur class of gardeners, in discovering that small birds will not penetrate through a series of black cotton threads stretched over the tops and amongst the boughs of the trees. We know for a certainty that white thread does not frighten them more than one or two days; neither does red coloured worsted; and we much suspect they will in time become acquainted with your black strings. We are, however, obliged to you for reporting it; and hope some other correspondent will try it and report the result. You will perceive that however useful your plan may be on a small scale, it can hardly be carried into effect where, perhaps, a plantation of ten acres has to be attended to.

CHRYSANTHEMUM (*H. H.*).—The north of India and China is the natural home of this flower, but it is only found wild on the mountain regions of the former country. In the latter it has long been cultivated, and the double varieties we now admire so much were originated in that country, and there cultivated to a higher degree of perfection than we can hope to attain. It is purely an autumn-flowering plant, and the earliest period we have seen it in bloom was in the middle of August. It is, however, possible that earlier varieties may be obtained hereafter, and also later-flowering ones, for both are sought after, and no doubt time and perseverance will accomplish both objects.

SOLFASTERE ROSE (*B. O. B.*).—Your Rose, which you say was budded last year and is now 10 feet long, has made excellent use of its time. It would hardly, therefore, be proper to cut it much back, as it must have a well-established stock. If it be planted against a wall it would be best to band it down and train it horizontally backwards and forwards at the bottom of the wall, not even cutting off the end. By this means you will have your wall well furnished, for shoots will rise abundantly from all parts of the horizontal stem, while they are far from certain to do so on the upright one. SolfaSTERE is far from being a free-blooming Rose, but the above is likely to induce it to flower better than severe knife work.

MANAGEMENT OF CAPE BULBS (* *).—You are quite right in potting your recently-received bulbs in sandy loam, and do not give much water until they begin to grow, after which increase both water and heat; and it is possible a very robust one may want a shift into a larger pot, but this is not likely. After flowering, gradually withhold water, so as to ripen and give the bulbs a rest, but while they are in a growing state heat and moisture are requisite. We have seen bulbs of the kind we imagine yours must be weighing 1 lb. each. If they start to grow at once there is a good chance of their flowering; but when later, autumn sets in before they do so, and then only bloom imperfectly.

CAMELIAS (*J. B. D.*).—You must send fresh specimens, for the others, under the circumstances, were passed aside.

NAMES OF PLANTS (*C. T.*).—It is *Asplenium marinum* in a luxuriant condition. There is no such thing as *Asplenium letitia*, but a plant like yours has been miscalled *A. latum*. (*C. S. N.*).—The Gymnogramma is one of the sulphureous sports occasionally met with in hothouses. It has no particular interest, nor anything striking in its appearance. Gymnogrammas are well known to be sportive. (*M. B.*).—Your shrub is *Garrya elliptica*. (*Hersham*).—The leaf is like that of *Agrostus*, but we cannot be sure without seeing a flower.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FEEDING POULTRY PROFITABLY.

E. F. asks us to give some instruction as to feeding poultry in the most profitable manner, and at the same time he complains of the quantity of food his birds consume. We are not surprised. We have often seen poultry yards inches deep in wasted food. We have seen two birds supplied with food enough to feed twenty. Fowls, like human beings, should leave off with an appetite. If they overfeed they lay the foundation of disease. First, then, no trough, no pan, no vessel of any kind to hold the fowl's food. The reason will at once be obvious. Fowls have no teeth, they have no means of mastication, and, therefore, their habit is to peck grain by grain, one at a time. In a trough a fowl takes a mouthful, which it has to bolt somehow or other to its great discomfort. Mouthful after mouthful follows, and then the bird becomes crop-bound, or squats about till it is seriously ill; this is the result of improper feeding, and, we unhesitatingly say, the inevitable result. It is a plain deviation from the laws of Nature. Fowls and all the tribe of Gallinacæ are intended to pick up their food grain by grain, and scrap by scrap. It is the condition of their health. While in search of food they find pieces of grass, herbs, small stones, and many little things that are essential to their health, although they escape our notice. It is also an incentive to exercise.

Whenever we want to succeed in having our pets in as good condition as wild birds, we must so far as possible confine them to the same habits of life, and we must make our arrangements a close imitation of the Pheasant, Partridge, and Grouse. These thrive and fatten on the stubble, and the apparently barren moor, while too often the petted fowl looks with careless eye on the barleymeal, and bread that lie about in all direction. The difference is, as between the appetite of a man who runs breakfast into luncheon, and with the help of a stimulating glass of wine lasts till dinner, which he can only peck at; and that of the man who runs home from the baker's after church on Sunday with a baked shoulder of mutton and potatoes under it, and who eats it in imagination all the way home.

The nearest approach to natural feeding is to give food by hand, and in small quantities, and scattered about. The most profitable food is ground oats. Let such a quantity as will be eaten be mixed and thrown by hand to the fowls so long as they will run after it—no longer. As soon as they appear indifferent about it, leave off feeding. If any appear on the ground you have overfed. In the midday give a little whole corn, but scatter it broadcast. Let the fowls have to look for it as Pheasants and Partridges search a stubble. Feed in the evening with meal after the same manner we have described for the morning.

Do not be led away by tender-hearted poultry-women, or by occasionally sulky poultry-men, when they say the birds are being starved and you can expect neither eggs nor chickens. If the fowls do not run after the bucket and the person who carries it they are not hungry; and if they are not hungry, they do not require feeding.

DEVIZES EXHIBITION OF POULTRY.

FEBRUARY 10TH AND 11TH.

THOUGH the numbers of entries at the Devizes Show last week fell somewhat short of those in preceding years, we can without restriction congratulate the Committee on their Exhibition of this year being quite the best collection of poultry ever yet brought together at this meeting. Two circumstances, most probably, tended equally to decrease the number of competitors—viz., first, it is now getting quite time to close poultry exhibitions for this season, as the breeding-time of most varieties has actually begun; consequently many fanciers are reluctant to exhibit on account of its obvious tendency to throw back many valuable birds in their early broods. The other reason is this: perhaps it would be well in future to lessen the entrance-money from 6s. to 5s. each pen, as that sum, combined with the incidental expenses of carriage, as it will be seen, from very long distances amounts in the aggregate to an outlay somewhat considerable when taken in ratio to the premiums offered, and this naturally deters the more distant competitors from subscribing.

We have on former occasions spoken highly of the Devizes Corn Exchange as a room for an exhibition of this kind, and

shall, therefore, simply now say that it is by no means an easy task to refer to any building better suited for a show of five or six hundred pens.

The Black *Spanish* were excellent as a class, but were scarcely in the perfect condition we anticipated. Mr. Brown, of Sheffield, took the principal prize with his well-known excellent pen, closely pressed by Mr. Lane, of Bristol, whose misfortune it was to have a really first-rate hen and cock both sadly injured about the combs and heads during their transit to Devizes. The third-prize birds of Mr. Rodbard, also of Bristol, comprised a lovely pair of hens; but mated with a cock so massive about the face as to be nearly blinded. His day as an exhibition bird is mostly bygone, and he appeared altogether listless and inactive. The Grey *Dorkings* were a grand collection, Viscountess Holmesdale standing, in spite of so capital an entry, far ahead of the general competition. Her ladyship's first-prize birds are too well known to be now specially described; but certainly they were not shown so well as heretofore. The second-prize birds were resy-combed ones, and were in much better condition than the others, though from the same exhibitor. They were a most unusually large pen of birds, but lacked much of the neatness and attractiveness of the first-prize specimens. The White *Dorkings* deserve especial mention, so much so, indeed, that in the single Dorking cock class of "Any colour," a White one became master of the sweepstakes. It is of very rare occurrence in such open competition. A peculiarly large fine old bird was exhibited in this last-named class, a Grey one, but so diseased about the comb as to render his chances of prizetaking hopeless. The class for either Black or Brown-breasted *Game* fowls was one of the best in the room, Mr. Fletcher, of Manchester, taking the lead with some first-rate Brown Reds shown in the most unexceptionable condition. We must here note, too, the success of this gentleman's yard in some of the other *Game* classes. His first-prize Red Piles, in the "Any other variety of *Game*" class, are, it is supposed, the best pen of Piles ever shown, and, somewhat strangely too, the cock is now fast approaching six years old, yet retains a marvellous condition, and still moults as true to colour as when a youngster. Mr. Fletcher's Black Red *Game* cock, the winner of the Society's silver cup for the "Best Single *Game* Cock," is a two-year-old; and should his condition prove maintainable up to his present standard he will be hard to beat anywhere. Mr. Whitwell's second-prize Brown Red was not in nearly the trim for exhibiting as when shown at Kendal a few weeks back. Mr. Dyas's Black Red, the third prize, is an exceedingly well-built, neat bird, but certainly "a small one." The *Cochins* were best in the Partridge-coloured and White varieties, which were really a show in themselves, even after the winners had travelled so far as from Oswestry and Kendal. Mr. Sykes's *Malays* were excellent. The Golden-pencilled *Hamburghs* were remarkable for the general imperfection of their combs; and it would be wisdom for exhibitors to bestow every care in their selections on this all-important point. Among the Golden-spangled were many of the best hens we ever yet saw. The *Polands* mustered strongly, and proved the best class ever yet seen of *Polands* at Devizes. The Sebright *Bantams* were so good that every pen save one obtains mention in the prize list; the cock in this one had a complete sickle-tail, though the two hens were of the highest character.

As it is always found at Devizes, the Buenos Ayrean *Duck* class was good and well-filled; the principal honour, however, travelled so far as Mr. Jessop, of Hull.

The *Turkeys* were few but capital; and when we mention the well-known names of Seamons and Fowler as competitors, none of our readers can doubt for a moment that the Ducks and Geese were as well represented as possible.

The management of the poultry on the part of the Committee admits of no improvement, and thus the order and regularity were unexceptionable. As we before hinted, however, if this Show were in future held a little earlier in the season, no doubt the number of entries would be considerably advanced, and therefore its pecuniary success greater.

SPANISH.—First, E. Brown, Sheffield. Second, H. Lane, Bristol. Third, J. R. Rodbard, Writington, Bristol. Commended, Rev. G. Hodson, North Petherton, Bridgwater; J. K. Fowler, Aylesbury.

DORKINGS, COLOURED.—First and Second, Viscountess Holmesdale, Linton Park, Staplehurst. Third, Mrs. A. Guy, Eaton Grantham. Highly Commended, Major Ward, Castle House, Calne; Mrs. M. Seamons, Hartwell, Aylesbury; Rev. M. Stark, Hull; J. B. Coleman, Beversbrook; T. R. Hulbert, Bradgeon, Cirencester.

DORKINGS, WHITE.—First, Mrs. H. Fookes, Whitechurch, Blandford. Second, Rev. G. Hodgson, North Petherton.

GAME, Black-breasted and other Reds.—First, J. Fletcher, Stoneclough, Manchester. Second, S. Matthews, Stowmarket. Third, A. H. Philpott and J. B. Weeks, Bromyard. Highly Commended, A. B. Dras, Madeley, Salop; A. Heath, Calne; H. Adams, Beverley; C. W. Brierley, Rochdale, Lancaster; G. Layard, Birmingham. Commended, A. B. Dras; J. Fletcher, Manchester; M. Billing, jun., Gravelly Hill, Birmingham.

GAME, Duckwings and other Greys and Blues.—First, J. Hindson, Everton, Liverpool. Second, J. Fletcher, Stoneclough, Manchester. Third, G. W. Langdale, Beverley, Yorkshire. Highly Commended, H. Adams, Beverley; S. Dupe, Evercreech. Commended, J. Wilders, jun., Croxton Kyriel, Grantham.

GAME, Any other variety.—First, J. Fletcher, Stoneclough, Manchester. Second, A. H. Philpott, and J. B. Weeks, Bromyard. Third, A. Guy, Eaton, Grantham. Commended, J. Fletcher; G. S. Cruwys, Cruwys Morechard Court, Tiverton.

COCHIN-CHINA, Cinnamon and Buff.—First, Mrs. H. Fookes, Whitchurch. Second, J. W. Kellaway, Merston.

COCHIN-CHINA, Brown and Partridge-feathered.—First, P. Cartwright, Oswestry. Second, H. Chavesse, King's Heath, Birmingham.

COCHIN-CHINA, Any other variety.—First and Second, G. C. Whitwell, Kendal.

MALAYS.—First, N. Sykes, jun., Mile End, London. Second, W. Watson, Kelly Farm, Calstock. Highly Commended, Master C. A. Ballance, Taunton; J. Choyce, jun., Harris Bridge, Atherstone.

HAMBURG, Gold-pencilled.—First, J. E. Powers, Biggleswade, Beds. Second, E. Payne, Wharf, Cardiff. Commended, Major Ward, Castle House, Calne.

HAMBURG, Silver-pencilled.—First, T. W. Walsh, Worcester. Second, J. E. Powers, Biggleswade.

HAMBURG, Gold-spangled.—First, N. Maitor, Doughton, Manchester. Second, M. Billing, jun., Gravelly Hill, Birmingham. Highly Commended, I. Davies, Harborne, Birmingham; W. Cuff, St. Fagan's, Cardiff.

HAMBURG, Silver-spangled.—First, T. Davies, Stow Hill, Newport. Second, Viscountess Holmesdale, Linton Park, Staplehurst. Highly Commended, Mrs. Pettat, Ashe Rectory, Basingstoke.

POLAND, Black with White Crest.—First and Second, T. B. Edwards, Lyndhurst, Hants. Commended, Mrs. Blay, the Poplars, Worcester.

POLAND, Any other variety.—First, Mrs. Blay, the Poplars, Worcester. Second, Mrs. Pettat, Ashe Rectory, Basingstoke.

BRAHMA POUTRA.—First, J. Hinton, Hinton, Bath. Second, Mrs. Seamons, Hartwell, Aylesbury. Highly Commended, J. K. Fowler, Aylesbury.

BANTAMS, Game.—First, T. H. D. Bayly, Ickwell House, Biggleswade. Second, J. Camm, Farnfield, Southwell. Highly Commended, T. Davies, Stow Hill, Newport. Commended, J. W. Kellaway, Merston; E. Payne, Wharf, Cardiff.

BANTAMS, Gold and Silver-laced.—First, T. H. D. Bayly, Biggleswade. Second, E. Jones, Bristol. Highly Commended, E. Jones; Rev. G. Hodson, North Petherton; E. Yeardeley, Sheffield. Commended, Mrs. Pettat.

BANTAMS, Any other variety.—First, E. Hutton, Leeds. Second, Mrs. H. Fookes, Whitchurch. Highly Commended, R. Brotherhood, jun. Commended, T. H. D. Bayly, Ickwell House; Rev. G. S. Cruwys.

ANY OTHER DISTINCT OR CROSS BREEDS.—First, S. Dupe, Evercreech. Second, J. Lamb, Highworth. Highly Commended, W. Manfield, jun. Commended, P. P. Cother, Salisbury; R. H. Nicholas, Newport.

GESE.—First, J. K. Fowler, Aylesbury. Second, W. Manfield, jun. Highly Commended, Mrs. D. Smith, Basingstoke; Mrs. Seamons, Aylesbury. Commended, J. P. Coleman, Beversbrook.

TURKEYS.—First, Miss Milward, Bath. Second, D. Smith. Highly Commended, J. P. Coleman, Beversbrook.

DUCKS, Aylesbury.—First and Second, Mrs. Seamons, Aylesbury. Highly Commended, J. P. Coleman.

DUCKS, Rouen.—First, J. R. Hulbert, Cirencester. Second, G. Hanks, Malmesbury. Highly Commended, D. H. W. Horlock, Corsham.

DUCKS, Black East Indian.—First, J. E. Jessop, Hull. Second, F. W. Earle, Prescott. Highly Commended, E. C. Phillips, Chippenham. Commended, Master C. A. Ballance, Taunton.

DUCKS, Any other variety.—First, T. H. D. Bayly. Second, E. Hutton. Commended, P. W. Brunnell.

GAME COCKS.—First, J. Fletcher, Stoneclough. Second, G. C. Whitwell, Kendal. Third, A. B. Dras, Madeley. Highly Commended, H. Adams; Rev. F. Watson, Suffolk; W. Long, Devizes. Commended, J. Fletcher; M. Billing, jun., Birmingham.

GAME BANTAM COCKS.—First, J. W. Kellaway. Second, C. W. Brierley, Rochdale. Third, T. H. D. Bayly. Highly Commended, J. Camm; W. Silvester, Sheffield. Commended, R. B. Postans, Essex; J. Camm.

SWEEPSTAKES.

SPANISH.—Prize, J. R. Rodbard, Bristol. Highly Commended, H. Lane, Bristol.

DORKINGS.—Prize, Mrs. D. Smith, Browning Hill House. Highly Commended, Viscountess Holmesdale, Linton Park.

COCHIN-CHINA.—Prize, J. W. Kellaway, Merston, I.W. Highly Commended, Major Hassard, Portsmouth.

HAMBURG (Pencilled).—Prize, J. Munn.

POLANDS.—Prize, J. Hinton, Hinton, Bath.

MALAYS.—Prize, W. Mansfield, jun., Portesham. Highly Commended, Master, C. A. Ballance, Taunton.

ANY BREED NOT MENTIONED, except Game and Game Bantams.—Prize, J. Hinton, Hinton, Bath. Highly Commended, J. Fares, Chertsey.

Mr. Edward Hewitt, of Eden Cottage, Sparkbrook, officiated as Judge.

BIRMINGHAM PERIODICAL POULTRY AND PIGEON SALES.—At the sale on Tuesday last there was a very large attendance of buyers, some from very long distances, attracted, no doubt by the disposal of Mr. Tomlinson's surplus stock. Several birds sold at prices averaging from 30s. to 25 5s., and were distributed in the counties of Nottingham, Derby, Lancaster, York, &c.; but many found purchasers in the town and neighbourhood of Birmingham. Altogether 220 lots were sold, and the competition for Cochins of all colours, Spanish, Game, Dorkings, Bantams,

and Pigeons, was good, the amount realised being nearly £200. Mr. Lythall the Secretary of the Birmingham Cattle and Poultry Show Society, officiated as Auctioneer.

NANTWICH POULTRY EXHIBITION.

THE fourth annual Exhibition of poultry has just taken place at Nantwich, and we are happy to say it has proved by far the best of any held by the Society. Confined expressly to a radius of thirteen miles from the Town Hall, most persons would naturally anticipate not only a very limited amount of entries, but would probably expect to find the generality of the birds shown of comparatively inferior character to those we meet with in shows open to the whole kingdom. In the particular case of Nantwich, the results are quite the reverse, the entries being upwards of 350 pens, whilst the specimens generally have nothing to fear from comparison with those of our most popular meetings. At the first meeting, four years back, some mistakes in properly selecting the various pens of necessity occurred, a poultry show then being quite a new feature in the locality; but, as time wore on, this difficulty disappeared, and now the judgment displayed in the penning of all varieties shows at a glance not only that many of our best poultry-yards exist in this neighbourhood, but that the exhibition of poultry is perfectly understood, and combined with the closest emulation: hence only is it that the exhibitors of Nantwich are so perfectly competent not only to well fill their own Town Hall at their local meetings, but also to take no meagre share of the premiums at any other shows where they dare the competition. The Committee evidently entertain as good the importance of the old motto, "all hands to the wheel;" none of them are idle spectators, every one seems on the best and most friendly terms with his fellows, and therefore all arrangements progress in the most perfect order and unbroken regularity. It would be well for some other committees to become copyists on this point, and so prevent the unpleasantness that must inevitably arise, and that too frequently, where each shifts to his utmost all responsibility on to the shoulders of his colleagues, so that at length the duties of committeemen are either absolutely neglected or grudgingly performed. We must not digress further, but proceed to give some of the leading characteristics of the Show.

The Black *Spanish* were the first objects that met the eye of visitors, and both young and old were in far better condition than might have been expected. Some of the pullets were of very first-rate character.

By the catalogue arrangement Aylesbury *Ducks* came next in order, and rarely has so close a competition been recorded. Both first and second prizes were faultless in colour and bill, and, still more strangely, were of precisely the same weight. There was one feature, however, that decided the preference: the first-prize pen were shown in fair breeding order; the second had evidently been more highly fed. The Rouens generally were very good, but had to submit to the Aylesburies when competing for the plate for the best pen of Ducks of either breed. In the "Any other variety of Ducks" were some well-shown wild Ducks, so thoroughly domesticated as to eat freely from the hand, besides some really good Buenos Ayrean Ducks.

All the *Geese* were good, and comprised the Embden, Toulouse, and Mottled varieties.

In *Turkeys*, except the first-prize, which were of the Cambridge breed, there was not anything of superior quality.

Both White and also Grey *Dorkings* were capitally shown; indeed, it is certain they were far superior to those of most of our exhibitions. The Partridge *Cochins* were as good as could be desired, and this variety succeeded in obtaining the Society's plate for the best pen of poultry of any variety exhibited. The Buff *Cochins* were not nearly equal to them, but the White ones were a very good lot. A very strong entry next competed for the Licensed Victuallers' Cup, given to the best Game cockerel (any colour) exhibited. A Nantwich victualler won it, but was closely pressed by several others; and, falling into his hands, the cup will, it was foreboded, rather prove a honorary than a profitable achievement, if the demands of the disappointed as to filling and refilling it are to be complied with. Of the Game fowls as a whole we cannot express ourselves too highly. As always appears to be the case at Nantwich, the Brown Reds took precedence of all other colours, though many first-rate Black Reds were present. Two old cocks were disqualified, being entered as cockerels. The Golden-spangled were the best of the *Ham-*

burghs, and the Silver-spangled of the *Poland* fowls. Some very good *Bantams* were shown in their respective classes.

The *Pigeons* were quite a favoured portion of the Exhibition, and the collection of small singing birds was scarcely less attractive.

Great credit is due to Mr. Rhodes, the Hon. Sec., for his courteous and prompt attention to everything connected with the Show.

The Judge of the poultry was Mr. Edward Hewitt, of Sparkbrook, Birmingham; for the *Pigeons*, Mr. C. Cotten, of Crewe, and Mr. C. Bowles, of Chester; and for the *Canaries* and other song birds, Mr. John Ankers, assisted by the *Pigeon Judges*.

As the weather proved most propitious a very great attendance ensued, and the Society has even still further increased its hold on the good wishes of the neighbourhood. This, combined with the promise of a larger subscription list for future years, betokens that the perseverance of the Nantwich Committee has obtained the reward it so well merited.

We published the list of awards last week.

WARNING.

AFTER my advertisement in the *Journal* some few weeks ago, amongst other applications was one from a "Mr. Ridgway Beswick Lodge, near Manchester." His second letter ran as follows:—"I am in want of some good Carrier *Pigeons*, and knowing you to keep some first-class birds, you will oblige by sending me a pair each of Duns, Blues and Blacks. Send them first-rate birds, as price is no object. Send me word when you have sent them, also your charge for the lot, and I will remit payment on receiving the birds." Then, he says, "Direct for Mr. Ridgway, Beswick Lodge, near Manchester, to be left at the Ashton Station until called for, as that is the nearest station to my house, and I will send my man down for them." Now, I did not like this style at all, and civilly requested prepayment; but I have never heard from him since. I suspected it was a hoax, and asked a gentleman who lives in Manchester to inquire if there was such a name and place near. He took much trouble, looking in the "Directory," and inquiring of everybody likely to know, but all to no purpose, until this week, when he heard from some manufacturers in Beswick, that "Beswick Lodge" is a beerhouse at the bottom of Beswick Street, and several inquiries have been made for "Ridgway," who is not known there, but suspected to be a member of the "Long firm."—T. COLLEY.

BEE-KEEPING IN STAFFORDSHIRE.

THE last two seasons with me have been very bad. The spring of 1861 found me with only one stock, which sent out a swarm on July 1st, which on September 1st did not weigh 1 lb. heavier than when hived; so I determined to try superposing. Having had a queenless hive presented to me, I gorged them with food for several days, and at evening, about dusk, put the queenless stock on the top of the swarm, thinking they would fraternise with and descend to those below. Little fighting ensued, not more than a score being killed; but what was my surprise in a few days to find, that instead of the queenless stock descending according to my wishes, the others had gone up to them, leaving tenantless the handful of comb they had made. Thinking it best to let them remain undisturbed as the queenless stock, which was a swarm of 1860, had most comb, I fed them liberally, leaving the part-filled hive below. They came through the winter of 1861-2 in good order, and, after being provided with a fresh domicile by cutting-out the top-board of the lower hives with the combs adhering, and fitting it in a cap-hive, are now my strongest stock; but they are two storeys high, the top-board forming the division having two side apertures each about 2 square inches area. Will the division affect their future welfare? and will it prevent swarming? As neither stock swarmed last season, which was as bad as 1861, I shall be obliged by learning the opinion of "A RENFREWSHIRE BEE-KEEPER," and hope to hear a better account of his apiary than I am able to give of mine.—A NORTH-STAFFORDSHIRE BEE-KEEPER.

BEES.—The *Apiculteur*, a French apiarian journal, contains the following remarks:—"Bees do not pass the winter in a state of stupefaction, nor do they sleep much longer during that

season than in any other—all that depends upon the work they have to do. There are at all seasons some working bees alive and active in a hive, and at the time when provisions are being got in there are many at work day and night without taking any sleep at all. Their slumber is very light at all times, for they sleep with their eyes open; the slightest noise, a vivid light, or a current of air, is enough to awaken them; but the warmer the hive is the easier it is for them to sleep; hence they consume much less honey in a hive situated in a quiet place, little exposed to light and air, than in one more exposed. But if the outer temperature rises very high, this favours the laying of their eggs, and then a larger quantity of honey is consumed. It is, therefore, easy to explain why in bee-hives placed close to each other the consumption of honey is different during winter; and this is a circumstance not to be neglected, because colonies which before winter seemed to have provisions enough to last them all through the month of March, may be reduced to extremities before the end of January, in which case the apiculturist must come to their assistance. If the bees have been able to enjoy an excursion or two since Christmas they will easily partake of the liquid food which may be offered them in a cup placed inside the hive; but if not, the food so administered may cause dysentery. To avoid this, honeycombs full of honey should be cut out of other hives where the supply is plentiful, and transplanted into needy ones. This delicate operation is performed in a cellar by the light of a lantern and with the aid of smoke. The colonies thus assisted must be left in the cellar, if it be not too damp, until a fine day comes to allow of their flying out a little. The hives from which the honeycombs have been taken must also be left in the cellar for twenty-four hours at least, during which the bees feed on the honey that has exuded during the operation.

OUR LETTER BOX.

DEATH OF CHICKENS (*Alpha*).—All parasites become fatal to chickens, but it is seldom we find them among the dung. The only worm we know is the tape-worm, and this is only common to Game. Parasites in chickens are two—the lice in the feathers, and the red-worms in the throat. The first are dislodged by dust and ashes, especially wood ashes mixed with a little sulphur. There is little doubt the second are caused by impure water. We fancy that living in a greenhouse and pinery they have, in scratching or searching for food, found some parasitical insect that would attach itself to anything that had life. It is unquestionable these would cause death by constant worrying. We doubt, however, whether they are flies; even small chickens are great enemies to everything that has wings.

BUYING STOCK (*An Old Subscriber*).—If you apply to Mr. Bailly, 113, Mount Street, Grosvenor Square, you will obtain what you require.

EARLY-CHICKEN MANAGEMENT (*Constant Reader*).—Is your crate covered at night? Cochins are very hardy. Your feeding is judicious. We do not see why they should die, unless they get a chill. The nights are still long and cold, and the hen cannot cover them as well at a month old as she can when they are very young. We do not think a large crate necessary. The ordinary rip that we have described so often, closed at the back and both sides, but open in front, to allow the chickens to run in and out between the bars is all that is required; and has the advantage that the back can always be turned to the wind, and that the front is easily covered up at night. They do not want hay. We have given bruised hempseed with success to young chickens, and in cold and damp weather we give stale bread soaked in strong ale night and morning. We also give them beer to drink. Chickens sometimes die at that age from vermin. If this is found to be the case on examination, a little oil put under the wings and a little on the crown of the head will be the cure. The prevention will be a heap of dust in their haunts. If they are exposed to cold at night they perish from it. The rip should not be large. It should be open only in front, and it should be carefully covered at night.

HENS NOT LAYING (*C. Ellis*).—Hens will not lay in the winter, it is contrary to their nature. Pullets will lay at that season, but only on the condition they shall reach the laying age in the winter. In providing for this it is also necessary to bear in mind that progress is very slow in the winter months, and that unpropitious weather will hinder or retard laying. Eggs have been more plentiful during the last fortnight, but up to that time they were unusually scarce. Cochins and Brahmas are the best winter layers. If you had had either of those in your pure-bred and eight months old, you would have had eggs.

HEN LAYING SOFT EGGS (*James Reid*).—As she has, a free run, and, therefore, probably finds a supply of limy substances, the evil is occasioned by an over-irritated state of the ovary and egg-passage. This, we have little doubt, arises from her being over-fed. Give her a dessert-spoonful of castor oil; feed her moderately upon boiled potatoes mixed with very little barleymeal, and throw some limy bricklayers' rubbish where she can readily have access to it. In a week or two the soft eggs will be succeeded by hard-shelled eggs.

AVIARY (*A Constant Subscriber*).—The back, a brick wall covered with ivy, will not be injurious to *Canaries*, *Goldfinches*, and other small birds. Try, and we will hope that you may be able to keep the ivy flourishing.

INCUBATOR (*Lex*).—You are quite right, the rearing of the chickens is much more difficult than hatching them. We will not trouble you for the extract you obligingly offer. Hybridising requires too much care, and the treatment varies too much to answer under one general query.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 47.8° and 33.8° respectively. The greatest heat, 62°, occurred on the 27th, in 1846; and the lowest cold, 18°, on the 24th, in 1860. During the period 136 days were fine, and on 116 rain fell.

THE ROYAL HORTICULTURAL SOCIETY.

It showed in our last notice of the report of the Council of the Royal Horticultural Society what was the real condition of the finances.

We showed that after all liabilities were paid the Society had only £3141 9s. at their credit wherewith to begin the world on the 10th of February in this present year. We also stated that the receipts during the year had been, on revenue and capital account together, £48,081 0s. 4d. We shall now glance at the way in which this and upwards of £7000 in addition has been spent. In fact, the whole expenditure on the year has been £54,016 3s. 9d., without any part of the debentures being paid off.

And first in the account comes Chiswick. Chiswick last year cost £2400 18s. 3d., rent, taxes, labour, implements, seeds, plants, and everything included; but to the credit of this must go £435 12s. 10d. received for garden produce and charges, which, in fact, reduces the expenditure of Chiswick to £1965 5s. 5d., besides the enormous quantity of bedding-out and decorative plants which it has contributed towards the garden at Kensington. Chiswick, therefore, in round figures, costs the Society £1965.

We come now to the "Expenses of Management" account. This includes salaries, printing, advertising, Journal, the two Committees, foreign importations, furniture, wages, &c.—in short, everything connected with what may be called the offices, and amounts to £5990 1s. 2d. The first item is for salaries and collectors' poundage—£1439 3s. 2d. How much there may be set down for the latter we do not know; but suppose the whole amount were applied to salaries, which includes, we presume, the plant-collectors, there is nothing to complain of out of such an expenditure. The work to be done in the offices of such a Society, where there is so much book-keeping, management, and correspondence required, cannot be little; and where men of education and of competent ability are necessary, the remuneration must be in accordance with the status of the Society and the ability of the individuals. "Printing, Advertising, and Stationery," £787 9s. 9d. seems a very large amount, seeing that it does not include either the Journal or the same items for the expense of the exhibitions. Taking the whole of the printing, including Journal, advertisements, and stationery together, it amounts to £3344 9s. 5d.; of which £1105 15s. 3d. is for the Journal, and £1458 5s. 5d. is for the exhibitions. Now a question naturally arises, Is the Journal worth such an expenditure? The main object for which this was established was as a means of communication between the Council and the Fellows. At the meeting held at the rooms of the Society of Arts in the Adelphi in 1859, Fellows of the Society complained that they never knew what was going on, the announcements of the Council being confined exclusively to one

No. 100.—VOL. IV., NEW SERIES.

gardening publication, and, as only some of the Fellows saw that paper, the rest were kept in ignorance of what was going on. It was upon this suggestion that the Journal was begun. The number of Fellows then was, perhaps, not half the number it is now, and consequently the cost of the Journal was proportionately less; but now that the Council advertise so liberally in the gardening and daily papers, we certainly do not see any necessity for a monthly Journal, and especially as not one tithe of the Fellows ever open it. For all purposes as regards the information to be communicated, a quarterly publication of modest pretensions would suffice, while all announcements of current events can be made through the ordinary advertising mediums as is done by all other public bodies.

The whole expense of the Fruit Committee during the year was £172 4s. 4d., and of the Floral £157 3s. 5d. These amounts speak for themselves.

The "Foreign Importations," £418 12s. 6d., we take to mean Mr. Weir's plants sent home, of which but little is as yet known. People are asking why it is Mr. Weir lingered so long about Rio, and did not penetrate at once to the district where greater success might have crowned his labours. It is nearly two years since Mr. Weir left England; and contrasting his labours with those of Mr. Fortune and Mr. J. G. Veitch in Japan, both of whom went and returned laden with treasures within two years, they certainly do not contrast very favourably. "Wages," which is exclusive of labour at Chiswick and at the Kensington Garden, is put down at £746 2s. 7d., and amounts to nearly one-half of the whole labour of the garden and conservatory. The miscellaneous—£431 14s. 9d. and law, £242 9s. 4d. complete the principal items in this account.

The next statement is "Expenses of Exhibitions," £9908 3s. 1d. This includes printing, advertising, and posting, £1458 5s. 5d.; prizes and medals, £2101 17s. 6d.; the "bands" played to the tune of £3022 7s. 1d.; and the tents cost £1672 9s. 6d. Police, making a new road, commission on tickets, &c., make up the remainder.

The "Kensington Garden Expenses" amount in all to £7261 0s. 5d., the principal items of which are labour £1823 3s. 2d.; rates, taxes, and insurance, put down by mistake as "rent, rates, taxes, and insurance," the rent being a distinct item, £1329 6s. 8d.; sculpture and ornaments, £1161 10s. 7d.; implements, manure, coals, and coke, £558 15s. 11d.; trees, plants, and seeds, £603 3s. 3d. Repairs sounds a strange item in the expenditure of an establishment where everything is supposed to be only a year old, but repairs have already been done during the year to the amount of £313 12s., or nearly the cost of the Fruit and Floral Committees together.

The interest on debentures amounts to £1817 14s. 7d., and the rent to the Royal Commissioners of 1851 is £2289 10s. annually. Upwards of a year being due on the 1st of January last, the amount stated in the account as being paid for rent to that date is £3318 12s.

We have thus gone over the leading heads of expenditure in the revenue account, which amounts altogether to £30,368 2s. 3d., and which, being deducted from the

No. 752.—VOL. XXIX., OLD SERIES.

income £31,381 13s. 10d., leaves a profit on the year of £1013 11s. 7d. This being the joint property of the Society and the Royal Commissioners, each takes their share of profit, which amounts to £506 15s. 9½d.

A correspondent, signing himself "COMMON SENSE," sends a letter to "one of our contemporaries," the whole gist of which is, that he regards it as "a ground for satisfaction" that the Society has spent so much money; and that having only £3100 in hand, the nature of the works is such it will require so much more to be spent before the whole can be completed. That's all. He does not gainsay a single statement we put forward in our last article, the sole intention of which was to show our readers what was the exact condition of the Society, and which really could not be gathered from the statements made at the meeting, and with difficulty from the published accounts.

ASTERS.

THERE is a danger in all reforms that they may become revolutions, when people, not contented with a fair modicum of change, are for overturning existing institutions altogether; and as such seems to be the character of a paper on "German Flower Seeds" which appeared in a weekly contemporary, I venture, ere it quite passes away, to say a few words on the other side of the question. I do this with less hesitation, because I have myself strongly condemned this system of "collections," especially in the matter of genuine florists' flowers, where promises are held out that varieties shall come true in their respective classes and preserve the character of their parents—about as likely a thing as that the chameleon will never change its colour, and therefore, as far as the general bearing of the paper is concerned, I am "in accord" with the writer. What I object to is the length to which he has carried it, and the manner in which he has laid the whip on the broad shoulders of the German seedsmen, when the fault is on our own side of the water quite as much.

The objections made are—1, The excessive number of varieties advertised; and 2, the equally excessive number of colours, and, having enumerated from one of the seed catalogues (and one is a fair specimen of all), 183 varieties, he recommends us to discard all but twelve, and that eventually all parties will be benefited.

With regard to the number of varieties. That there are these different—dwarfs, tails, bouquets, hedgehogs, &c., is evident enough; and it may be that some people admire flowers like a hedgehog; (can't say I do any more than I admire the beast himself), but to say that there are only two kinds worth growing is rather too far a shunt in the other direction.

The following I believe to be well worth having:—1, Truffaut's Pæony-flowered; 2, Perfection Pæony-flowered, or Perfection simply in some catalogues; 3, Dwarf Chrysanthemum-flowered; 4, Cocardeau or Crown Asters; 5, Betteridge's Quilled. Where exhibitions are in view some would also add the Giant Emperor. The first two sorts differ rather in shape than in anything else, the Perfection being more imbricated, called by the raisers in France "*imbriqué*," while the others are "*pinvaine*." There is, I know, sometimes confusion in these classes; but all I wish to imply is, that there are two classes of the Pæony-flowered Asters differing mainly as to their form. With regard to the third class, it is one of the greatest acquisitions possible for us small gardeners; its dwarf habit, the freedom with which the flowers are produced, and the size of the blooms, making it quite an autumn gem. Entirely distinct from any of these are the Cocardeau, Cockade, or Crown Asters, having either scarlet or blue guard petals, and the centre filled-up with white. I know of no Asters more distinct than these are, or more pleasing. Then as to Betteridge's. I mention them because they are, as far as I have seen, the very finest of the Quilled varieties. Some of the German Quilled are very good, but I have never seen any that on the whole equalled these, and they invariably take first prize at the great metropolitan exhibitions. Here there are five, or at any rate four, sorts of Asters well worth growing—an opinion in which I think I shall be borne out by the majority of those who have grown them. And then with regard to the colours. Indubitably there is need of reform here. The difference between tweedledum and tweedledee was not more imperceptible than the difference of tints that these Asters, Stocks, Zinnias, &c., are made to assume. A rosy car-

mine and a carmine rose, a pale flesh and a light pink, do certainly sound very much alike, and, what is more, are very much alike; but I think the saddle has been hardly put upon the right horse.

On referring to the schedule of the Royal Horticultural Society, I find that exhibitors are required to show 24 distinct varieties in both, what are called by them, Tasselled and Quilled Asters. Here, then, according to the estimate of what ought to be the highest tribunal in the land for floricultural purposes, there are, instead of 12, 48 varieties worth cultivating! But I believe this to be a great mistake. It is possible in the Tasselled varieties, by selecting from the Giants, Emperors, Chrysanthemum-flowered, &c., to find 24 which may be distinct; but to do so in the Quilled ones is utterly impossible. I have over and over again gone over the stands as exhibited at Kensington and the Crystal Palace, and never have been able to make out more than a dozen, and even that with some difficulty. It is of no use, then, calling it a "German humbug," while we are ourselves encouraging them to carry it out and to fleece us. If we are really sincere in our endeavours we must begin at home. Charity is said to begin there, and certainly reformation ought. When exhibitors are expected to do less, then seedsmen will not urge their foreign correspondents to send them over distinct colours when no such distinctness exists. Nor do I see in what other way the difficulty is likely to be abated. It is perfectly true that no advantage is gained by purchasing the smaller-sized packets, as then one only obtains a larger proportion of the indistinct varieties; but if societies would say that they do not look for such a large number of colours, we should in that case be likely to see a change.

I may, perhaps, seem to be laying too great a stress on exhibitions as affecting these things, but those who know the progress of horticulture are aware how much they have to do with them. When a flower is thrown into the shade in schedules it very soon ceases to be so extensively grown; and who does not know that the amazing increase in the popularity of the Rose is due, in no slight degree, to those national exhibitions at which eager competition brings together people from all parts to show their flowers and to take a leaf—a Rose leaf—out of their neighbours' books? To regard them a show, as only a means of making money, is taking a very low estimate. It does more—it acts as an encouragement on all concerned when properly managed. And when a man finds that his neighbour Tomkins, with only half as much ground as he has, has walked off with a first prize for Roses, he begins to think, "Why shouldn't I do as well as Tomkins?" And then the desire of doing likewise comes in, and next season sees Smith very close on Tomkins' heels, and the following season perhaps ahead of him: therefore, I say, these reformations must begin here. Do not let them be too sweeping—nothing will be gained by that; but the good sense of the public will, I should think, prevent that.

We have to thank the foreign seed-growers for most of the really good additions to our novelties, and especially in Asters. Do not let us now deal too harshly with those who have so largely benefited our autumn-gardening.—D., Deal.

OLD ROSES *versus* NEW ROSES.

THE crafty magician in the "Arabian Nights," cried "new lamps for old;" and "new Roses for old ones" appears the annual cry of our neighbours across the channel. For one, I must confess myself heretic enough to doubt the value or wisdom of the exchange, particularly in the face of many of the importations we have received during the past few years; not that I hold novelty objectionable *per se*, but only when it is made the cover of unfounded pretension, or the medium for passing off mediocrity as sterling merit. And this holds good with respect to Roses as well as to graver matters. I could point out fifty or sixty floral impostors at least, whose only pretence to a place in the catalogues is their novelty, by virtue of which they exclude older and better kinds, which, consequently drop out of cultivation and are lost. It is quite certain that our nurserymen must, of course, repay themselves for their risk and expense in importing novelties. Twenty or twenty-five francs is the usual price for each new kind, without the expense of carriage; so that two or three plants of forty or fifty varieties, amount to a considerable outlay, which takes some getting-back, without reckoning any profit upon the enterprise.

On critically examining the lists since 1859, by the test of observation and experience, I find about six is the annual average of fresh varieties really deserving to be considered as acquisitions, and even many of these might be dispensed with, being equalled, if not excelled, by kinds already in cultivation. This has been particularly the case among the introductions of the last seven or eight years, during which, with the exception of *Comtesse de Chabillant* and the *Senateur* (perhaps *Santhenay*, though it is shy), no Rose of paramount distinctness and excellence has come out, though there have been several undeniably good.

What we want among the Perpetuals is such Roses as *Brennus*, *Blairi* No. 2; *Coupe d'Hébé*, *Paul Ricaut*, &c., among the summer Roses; or, let us take a bloom of the common *Cabbage*, and stain it with various shades, from the deepest crimson to the palest blush, to represent the type desirable to be attained in the autumnal bloomers. The foreign raisers appear to have descended into a bad and defective strain. The full, firm, globular, deep-petalled form, with plenty of "stuff" in it, has given way to large, it may be, but loose, "flopperty" blooms. In many cases, where size has been obtained it has been of a peony-like character, with irregular, jagged, and pointed petals, subversive of symmetry and offensive to taste. *Madame Furtado*, so much puffed-up two seasons ago, has been, perhaps, the nearest approach to the old and desirable style of flower; but it is a bad doer and grower, and the blooms of it shown at exhibitions are no "criterion" of its worth as a garden decoration.

Now that our own rosarians appear to have taken up in earnest the task of raising seedlings, we shall, no doubt, obtain some real advance in England's national emblem. They not only know the character of flower required, but are not likely, for the sake of their own reputation, to foist tinsel and paste on the floral world for true gems.

I shall just make a few remarks upon what, in my humble opinion, are the most noteworthy varieties which have appeared since 1859, and follow them with a list for comparison of older favourites, none of them, I believe, of later date than seven or eight years ago.

Among the new kinds of 1859, I am disposed to believe the following are the best—indeed, the only ones for that year necessary to retain as additions to our stock. *H.P.'s*, *Anna Alexieff*, a really good Rose, of the style of *Baronne Prevost*; *Anna de Diesbach*, large and showy, but loose-centered; *Belle de Bourg-la-Reine*, good; *Comtesse Cécile de Chabillant*, or, in short, "Chabillant," the light Rose of the past seven years; *Eugène Appert*, fine colour and habit, but of defective form, one of the "Moutan-petalled" class; *Armide*, fair; *Empereur de Maroc*, small but dark, and well-shaped. *B.*, *Dr. Berthet*, dark, good. *Teas*, *Homère*, *Madame Damaizin*, and *Madame J. Halphin*, free-growing and good. *Noisettes*, *Celine Forestier* and *America*. I am not sure whether *Triomphe de Rennes* belongs to this year.

From the list for 1860, I have taken the following:—*H.P.'s*, *Gloire de Santhenay*; *Louis XVI.*; *Madame Boll*, not free in autumn; *Madame C. Crapelet*; *Senateur Vaisse*, the best high-coloured Rose since *Général Jacqueminot*, and superior to that as a florists' flower, the Rose of 1860; *Vainqueur de Solferino*, a free bloomer; *Victor Verdier*, another "Moutan-petalled" flower, but bright and free, and late-blooming. *Teas*, *Duc de Magenta*, *Madame Blachet*, and *President (Paul's)*.

For 1861, I have noted *Duc de Cazes*, very dark; *General Washington*, large; *Madame Furtado*, over-rated; *Madame Pierson*, tolerably good; *Princesse Mathilde*, very dark but small, late bloomer, as is also *Jean Bart*, another small dark flower; *Reine des Violettes*, inferior, but peculiar; *Triomphe d'Amiens*, useful as a dashed or striped variety, of which there are few. *B.*, *Catherine Guillot* and *Modèle de Perfection*, both of which are improvements on *Louise Odier*. *Tea*, *Boule d'Or*.

I think that the past season, 1862, will afford us more good Roses than any of those I have previously remarked upon. The following have been shown well, and from personal acquaintance with their behaviour in the ground, corroborated by what I have observed and gleaned at the nurseries, I should say several promise to be first-rate, and many more to be good. *H.P.'s*, *Alphonse Damaizin*, *Charles Lefebvre*, *François Lacharme*, *Louise Darzins*, white. How badly we want a really good white Perpetual! I doubt if this will supply it. *Maréchal Vaillant*, *Madame Boutin*, *Madame J. Daran*, *Madame C. Wood*,

Maurice Bernardin, *Monte Christo* (query, *Léon des Combats* over again?), *Notre Dame de Fourvières*, *Professor Koch*, *Robert Fortune* (large incurved), *Souvenir de Comte Cavour*, *Vicomte Vigier*, *Wm. Pfitzer*. *Madame C. Wood*, *Professor Koch*, *Maréchal Vaillant*, *Vicomte Vigier*, and *Wm. Pfitzer*, are good late bloomers, and *La Brillante* is very free. The *Teas* I cannot speak upon from actual knowledge.

I shall now proceed to give a list of the older favourites. *H.P.'s*, *Alexandrine Bachmeteff*, type of the flat double flowers; *Alphonse de Lamartine*, nearly as regular as *Chabillant*; *Auguste Mié*, a truly royal flower; *Baronne Prevost*; *Baronne Hallez*; *Caroline de Sansal*; *Comte de Nanteuil*, a "Coupe d'Hébé"-formed flower; *Comte de Paris*; *Cornet*, a Perpetual Cabbage; *Duchesse d'Orléans*, *Duchess of Sutherland*, gems of size and symmetry; *Général Brea* and *Bedeau*; *Gloire de Parthenay*, and *Gloire de Vitry*, two splendid varieties, large, full, and free-blooming; *Lady Stuart*; *Louis Buonaparte*; *Jacques Lafitte*; *Jules Margottin*, the Perpetual *Brennus*, and still monarch of the carmine class; *La Ville de St. Denis*, superior to *Madame Furtado*, and a better grower; *La Reine*, really a queen of queens; *Léon des Combats*, as good as *Santhenay* when well done and in trim; *Madame de Cambacères*, for all purposes the soundest Rose, perhaps, grown; *Madame Vidot* and *Mrs. Rivers*, exquisitely beautiful in form; *Prince Léon* (what Rose surpasses this?) perfect in shape and colour, free in bloom, though of only moderate growth; *Reine des Fleurs*; *Sydonie*, a real globular flower; *Triomphe de Paris*; *Wm. Griffith*; and *Wm. Jesse*. *Bourbons*, *Madame Angelina*, *Queen*, *La Quintinie*, *Paul Joseph*, *Pierre de St. Cyr*, *Reveil*, *Souvenir de la Malmaison*, the best light Rose still, show that there has been less advance in this section than in any other. *Teas*, *Devoniensis*, old but unsurpassed; *Bougère*; *Goubault*; *Moiret*; *Souvenir d'un Ami*; *Gloire de Dijon*, scarcely a Tea except in scent, for its leathery camellia-like foliage and vigorous habit assimilate it to the strong-growing *Bourbons*. *Noisettes*, *Lamarque*, *Solfaterre*, and *Narcisse* (query, a Tea?)

Now, whether the Rose has undergone that improvement so frequently boasted of may well be doubted after comparing such varieties as enumerated above with their more modern rivals. Some advance may have been made, perhaps, in colour, especially in the darker kinds; but even that will disappear if the clouded, shaded, and uncertain nondescripts now so prevalent are allowed to become an established taste. Want of space prevents me from making this paper so exhaustive of the subject as I could wish; nevertheless, it may serve to suggest matter for consideration to fellow rosarians. Meanwhile, whether new or old, *Floreat Rosa!*—W. D. PRIOR, *Homerton*.

DIVISION OF VINE-BORDERS.

THE utility of this may be questioned, and the idea may seem novel, and, perhaps, interesting to some; but improvement after improvement comes looming in the distance, and in the process of time they become immediate realities. The plan I advance is, that the roots of every individual Vine be separated from those of its fellows by a four-inch brick wall running transversely through the border, both outside and in.

By the above means more command is gained over every plant. First, in withholding or giving moisture according to the individual necessities and constitutions of the plants, for, in general, vineries are planted with different varieties; hence the application. Second, it facilitates the lifting or transplanting of any individual Vine, and completely obviates the necessity of crippling the roots of that particular Vine, or those of its fellows. Third, in renewing the soil, a compost may be given suitable to the appetite of any variety of Vine. Again, when a limited number of Vines are grown, and a continuous supply demanded, when the Vines wear out from constant hard forcing, the replanting of the house would be easily effected by taking out every alternate Vine, or every third Vine, so that in three years the house might be renewed, both in plants and soil, and never miss a crop. These brick walls would also assist in airing and keeping the border sweet.—P. M., *Combe Abbey*.

[We think all your reasons good ones, except the airing of the border. We do not see that solid brick walls would help that much. Many years ago Mr. Mearns planted his Vines in separate pits or boxes, so to speak; and at one of our best places, we recollect some fifteen years ago seeing early Vines so planted in separate brick boxes, and a flue below them, which

answered well, and permitted of changing and renewing as you suggest. In fact, no doubt the plan would be more general but for the expense, gardeners finding enough of trouble to get a border done, let alone dividing it with walls.]

PLANTING POTATOES ON THE RIDGE SYSTEM.

ONE correspondent, "D.," says, "I intend to plant sixty acres of Potatoes on the ridge system, as I am certain it will prove the right plan. The question is, How? Your garden method is, of course, out of the question. We find manure a necessary adjunct for a good crop, and the width of the ridges must necessarily be determined by the width between cart wheels, which in most cases is 5 feet; hence 2½ feet must be the width of each ridge. This I contend is not a fair trial, as there is not a sufficient width of earth on the top to secure room for a large quantity of good tubers. Supposing, however, that it is so, or is made so by deep cultivation between the ridges, and moulding-up twice, then how would you plant the sets? On the manure would not be safe. Besides, it would be too deep if ridged-up with the plough (8 to 12 inches). Would dibbling by hand on the top of the ridge, after the plough, do? Again, supposing 5 cwt. of guano per acre were sown broadcast and the ridges closed-up at once from the winter "till," the guano would be all there, and the ridges might be made any width. How would the dibble do then? Is 3 feet too wide for field cultivation?"

It is, according to my judgment radically wrong to apply raw manure in the drills when planting the Potato. It must be bad practice to place a pulpy tuber in a mass of sweltering corruption! The microscope shows the Potato to be one of the most delicately-constructed vegetables in creation, and even should the sets escape the festering evil, when in a poor soil dung is used after this manner under the idea of making the most of it, the young plants may grow away very freely at first; but as the roots lengthen, they do so into a barren soil—an abundant machinery with a scarcity of raw material—just when the formation of young tubers and the advancing state of the growth of the plants require an extra supply of nourishment. The start they had at first secured a vigorous foliage, to become stunted, starved, and unfruitful for lack of nourishment. But "D." finds "manure necessary," whereby I presume his land is light. I would, therefore, advise eighteen or twenty loads per acre to be spread and ploughed and well worked into the body of the land immediately, for properly the dung should have been administered last November; and if 3 cwt. or so of superphosphate of lime were sown broadcast just before the land is ridged-up, it would do no harm. If the land is well drained and has been pulverised with the subsoil plough to the depth of 18 inches or 2 feet, and so made permeable to the warmth and moisture of the atmosphere, I should consider that to be far before the most bountiful application of raw dung for the Potato now, if it were coupled with a top-dressing of lime or guano at planting time.

Lime is especially favourable to the growth of the Potato, and in some form or other is generally present in plants. Light lands require it in a less proportion than heavy soils, though even light soils are rendered more compact in consequence of the lime attracting moisture powerfully from the air. It cannot prove but beneficial to a clay, for it not only destroys the myriads of insect life to which moisture is congenial, but speedily converts to vegetable mould the stubborn fragments of previous crops, besides acting on the inorganic ingredients brought forward by the subsoiler and rendering soluble the salts of the earth along with the acids, and adapting them for the nutriment of vegetable life. Talk of the "earth being in its dotage" on account of the "exhaustion of vegetable mould," is nonsense, so long as there remains a subsoil to be brought up every few years to the action of a winter's frost and then a dressing of quicklime to tackle it. On a stiff clay I would use from seventy to eighty bushels of quicklime, procured fresh from the kiln, and spread it, not over-slacked, on the surface of the land just before ridging-up. If a light soil and guano should be decided upon, I would sow it broadcast just before ridging at the rate of from 10 to 15 cwt. per acre.

The manner in which I have said I would apply the dung, &c., does away with the necessity of trundling cart wheels between the ridges, and of the plough to split the ridges again for the purpose of covering over the dung. I should not like to

trust to a thirty-inch-wide ridge on good ground—3 feet in that case for the field culture of medium-topping sorts of Potatoes, would do very well. For the very large-tubed and branching sorts I should prefer a forty-two-inch base for my ridge to rest upon, and for it to be formed 1 foot broad at its apex, which could be eventually achieved by passing a light roller over the tops of the ridges. In Shropshire, where they manage these things better—at least, in so far as regards the cultivation of the Swede Turnip—I think, than in any other county, barring, perhaps, some parts of the county of Angus and thereaway, they would put a horse to a double mould-board plough and finish off tidily between the ridges almost as fast as a man could walk.

Unless "D." is satisfied with his ploughman's accomplishments in this matter, and on so large a scale, if I were he I really should feel greatly inclined to advertise in the *Hereford Journal* for a man, who is an adept in ridging with the plough, to come from the neighbourhood of Ludlow, or the radius from thence to Shrewsbury, for the occasion. I have enjoyed the sight of whole fields in ridges about there struck out to the nicest admeasurement, and as straight as ramrods.

Yes, the dibble would be the instrument for the field; the sets should be placed 7 or 8 inches deep, and I would set my face entirely against after-moulding. By hoe and by hand I would keep down the weeds and pick off the blossoms, for from them we may anticipate seed, the formation of which compels nature's exertion to the uttermost, and, of course, at the expense of the tubers, of which in due time, and the Fates being propitious, I would guarantee a crop on our ridge system to far surpass that on the old pottering, moulding-up plan so long the vogue.

The way I have dovetailed a compromise between the garden and the field for "D.'s" consideration is one which I hope may suit his views. What I have written I have not written without regard to diffidence. I should be sorry to mislead by advising a system which I have not proved by trial; still I have confidence sufficient in my recommendation to say, had I the opportunity I would work it out. Another correspondent, "C. S.," who inquires "whether Potatoes can be planted efficiently with the plough on the ridge system?" is answered by the above. To "D." of Newcastle, I answer, what I mean by the "flat" is the old system of burying the sets in the ground and moulding them up afterwards as they grow, in contradistinction to laying the sets on the surface of the soil, and then casting over them with a spade the mould from the centre between the rows, which thus constitute the ridge and trench system, and the Potatoes do not require to be moulded afterwards.—UPWARDS AND ONWARDS.

TEMPORARY DECORATIONS OF ROOMS FOR FESTIVE OCCASIONS.

A CORRESPONDENT has very properly called the attention of the Editors of THE JOURNAL OF HORTICULTURE to the important subject of decorating public halls and other places of resort on special occasions, like the auspicious one to which the British public are looking forward with so much interest at the present time—the marriage of the Prince of Wales.

Although the art of applying material so as to produce a pleasing and beautiful effect, has been studied by a class who have dignified their calling by the high-sounding term of Decorators, there are many who are obliged to undertake the practice of the art themselves in times like that which is now approaching: therefore, a few hints may be useful to them.

When we see the manner in which some of our churches are decorated at Christmas as compared with what they were twenty years ago, it is apparent that one of the most important items for temporary decoration, evergreens, has not hitherto entered so freely into the general display of public rooms as they might be made to do. It is, therefore, chiefly with a view to urge their claims to notice, that I am induced to repeat much of the substance of an article I formerly contributed, adding such other matter as may seem necessary to make the subject fully understood. At the same time I hope, after the event now approaching is over, some readers of this Journal will report the features of any particular place that was tastefully and yet economically decorated, for when a good display has to be made at a trifling or reasonable cost, the items that compose it must be cheap and plentiful. Mechanical men generally look on manufactured goods as the most proper for every purpose, useful or ornamental; hence the decorative features of public rooms

in large towns generally consist of drapery with some fanciful disposition of the lights used, evergreens being but sparingly employed. Perhaps the inability to obtain these in sufficient quantity may have been one preventive to their general use, or a sort of dogged adherence to pre-existing custom may have kept them away. Certain it is, that foliage has latterly become more fashionable as a copy for ornamentation, whether in embroidery, carving, or sculpture; and since such is the case, assuredly the original itself ought to be introduced wherever this can be done with advantage.

Of late years most large rooms intended for public assemblies have been more or less embellished by the architect. I mean those that have been built during the last twenty years, and more especially those that have been erected during the last ten years. Such rooms necessarily require another kind of temporary ornamentation when they are to be temporarily used for a purpose other than that they are daily wanted for. Rich cornices, mouldings, fluted columns, and elaborately carved capitals, friezes, and the like ought, of course, to stand out in bold relief, and what additional decoration is done ought to be of a kind not to interfere with them. The colour of the walls has also a considerable bearing on the kind of decoration to be used; and if the general hue be dark, as, for instance, oak panelling or such like, evergreens cannot well be introduced, excepting with drapery of a light colour. If, on the other hand, the ground and principal colouring of the walls be light, evergreens may then be used with advantage in considerable quantity, and in various ways, especially if the room be without much architectural ornament, but large and lofty.

Assuming, therefore, that a room of this kind is the one to be dealt with, the first thing to do is, to ascertain where nails can be put in without injury to the work, and so work the materials accordingly; for, as the object aimed at is simply to give a decorative appearance to the place for a very limited time, as little damage to permanent works ought to be inflicted as possible. Let us now take a view of the kinds of evergreens best suited to such a purpose, and in the first place it is right to say, that however much we may try to imitate the natural features of vegetation, when we mutilate or amputate its parts we cannot under any circumstances put the same together in any form to resemble them in their natural condition. A certain amount of artificial workmanship must, therefore, at all times be evident; but the more carefully such work is concealed the better. All clumsy work especially ought to be kept out of sight. As Nature in general presents to our view only one side of a leaf, and that, of course, the best side, a similar arrangement ought to guide artificial work as well, but as this cannot always be done, it is better to use only such foliage as presents a tolerably good appearance on both sides, as well as possesses the good property of a stiff leafstalk, the leaves thickly set on the bough, and of a substance strong enough to endure, without withering, as long a time as possible. It is, of course, difficult to find all these qualities united in one plant, but the nearer it approaches being so the better it is adapted for the purpose here intended.

Sometimes a thick-set branch is not so much wanted as a loose feathery one, and very often a flat branch of the latter kind is very convenient to place against a wall. For this purpose nothing is better than the common Laurel, which may be worked into a very nice cornice-piece by selecting branches of about 18 inches wide, more or less, as the size of the room requires, and nailing them to a narrow slip of wood of the same colour as the walls, the tips of one shoot overlying the base end of the other in such a way as to form a nice flat surface. These prepared cornice-pieces as they may be called, can be easily attached to the angles of the room where the cornice usually is made, and the leafy figures will sit close to both ceiling and wall, spreading out in an open spray-like form a foot or more each way. Some other shrubs may do as well as the common Laurel, but I do not know of any thing that will do better, the regularly set and stiff foliage showing to great advantage against a white or pale-coloured wall or ceiling.

Similar wreaths might be made to hang down any naked corners, or where some projection seemed to require relief, taking care of course not to overload the room with too much; but if there be very large spaces of naked wall, it would be better, in addition to the cornice-work noted above, to prepare a few flat pieces of evergreens to fasten upon such spaces. These may be made easily enough by having a small piece of board not more than 6 or 8 inches square, upon which nice flat pieces of evergreen may be nailed with their points all outwards. If a little care be taken in assorting their thick ends so as to hide the board and also their cut parts, the whole will appear a flat uniform surface of evergreens, the outside of all being to the front. These prepared evergreen pictures, as they may be called, may be of any size, but few rooms will require them more than from 3 to 4 feet in diameter. If there be no nails in the walls to which they can be suspended, a string to the cornice where a nail can be put in will do. Observe, these masses of dressed evergreens as well as those forming the cornice-work of the room ought not to be too thick and dense, as feathery open pieces showing their foliage in front of the wall and ceiling are all that is wanted. Rosettes of white and pink with a small piece of fine wire will do to fasten them to the evergreens, and they may be used rather liberally. In those masses occupying the plain wall which, as above, we have called evergreen pictures, these rosettes may be arranged in some fanciful form, as a circle, star, shield, or any device that may be most appropriate. The event the decoration is owing to may suggest either a monogram or any other feature that could be carried out easily, clearly, and yet simply, for the most homely plainness is better than any badly executed device of greater intricacy.

The above remarks refer more especially to large rooms having no architectural ornament of their own; but as many possess beauties which it would be improper to hide, another description of ornamental work must be adopted. Assuming a rich cornice to surround the room, the side walls below this may be rendered gay with evergreens tied-up in long continuous festoonwork. somewhat thus:—

CEILING.

The diameter of each semicircle should not be less than 6 feet, unless in small rooms; but if we take 6 feet as a standard the radius or dip of the festoon ought to be 3 feet at least. The character of the room and its fittings will, however, determine the size of the festoons, and at all places where they finish, a drop or pendant of the same character may hang down by the wall. In making the festoon, I have found short twiggy pieces of Ivy, as the spur piece from some old tree or wall that had not been cut for many years, short leafy twigs of about a foot long with not too much old wood about them, answer best, and are easily fastened to a length of small string of a dark colour so as not to show. The operation of making these festoons is quick

after a beginning is made. A quantity of small twiggy pieces of Ivy are prepared, and one end of the string is fastened to a nail or hook anywhere, while the person gives the string a hitch round the thick ends of one or two pieces of Ivy, and a sort of knot is formed by such hitch. One or two more pieces of Ivy are fastened in like manner to the string a few inches farther on so that their tops hide the base of the former piece, and this is continued to any required length. The end at starting being temporarily fastened to something is a great advantage. We have, however, generally found that pieces of 6 or 8 feet long were quite long enough to carry, as they can easily be united on the spot where they are wanted.

A little care in selecting suitable pieces of Ivy and in tying them on will insure a uniform and nice-looking wreath sufficiently thick to hide the thick ends of their stems, and not so thick as to appear bundled.

Other evergreens—as Box, Laurustinus, Phillyrea and the like will do as well as Ivy, but not better; while common Laurel, having its leaves all arranged flatways, does not answer so well. Portugal Laurel does better, and any evergreen having leaves of sufficient firmness to remain without flagging for the length of time required will do, if they are not too obstinate in showing too obviously a reversed position when accidentally placed that way. I have never been able to do much with Hollies on this account. Their weight, rigidity, and prickliness render them intractable objects to deal with, and unless they have their own way they look badly. Generally speaking small-leaved shrubby plants look best, and after trying a great many things we have found Ivy the most useful. The tufts of berries are an improvement rather than the reverse, and we have sometimes taken the trouble to dip them in a sort of batter of plaster of Paris, thus giving them the character of a bunch of white berries; but as the process is troublesome it has rarely been done on an extensive scale.

I may observe that, besides the upper part of the walls of these rooms being hung in the way described with this festoon-work, the ceiling may also be crossed in various directions in like manner, taking advantage of anything by which the festoons can be suspended from the ceiling. A lamp-hook is very useful for this purpose, care being taken that the evergreens are out of the reach of the lights. The downward curves of these festoons should be sufficiently graceful without appearing to crowd the roof or lower it. Sometimes festoons from the central lamp-hook may be made to radiate to the ceiling in all directions; but it is better not to crowd too much, and the appearance of festoons is not so good when viewed in any other direction but that of facing the observer or diagonally to him; endways they are bad, and so also when they are crowded. These festoons, whether against the side walls or suspended from the ceiling, may all be more or less ornamented with rosettes—pink and white alternately being the best, and not the two colours blended in one. If the room seems to require more evergreen decorations, small star-looking objects may be made by sewing about a dozen common Laurel leaves to a card, arranging them in a whorl-like form about a foot or more in diameter. These may be fastened against any part of a blank wall (a rosette ornamenting the centre of each), and they will produce a good effect; for, although evergreens add life to a scene of this kind, too much of them becomes heavy and cumbersome.

Besides the above method of using evergreens, they may also be tied in like manner to any object that may be turned to account. I have sometimes used strong wire or small iron rods bent into scrollwork and other fanciful forms, which may be stretched in various ways across a room, and fastened-up against the walls in the character of brackets or cantilevers, taking care that all the parts of the framework are distinctly seen through. Sometimes from the brackets or scrollwork pendants may be hung; and there are many other ways of increasing the general effect, only do not by any means crowd any parts. Any lettering or fancy device rendered necessary by the character of the festivity may be worked in evergreen as above, and many other devices suitable to particular places may be adopted. Shrubs with berries on may now and then be worked-in with good effect. Privet would have been very useful this way, only its berries being black do not show so well; and, as before stated, Holly is obstinate, and not adapted for small work.

These observations are intended for rooms having light-coloured walls and ceilings; but for oak-panelled or dark-coloured ones drapery must be used. If the wall be good, and to a certain extent ornamented by breaks or panels, I would not cover the whole with stripes of white and pink calico, as is often done, but drape the upper portion of the room with festoonwork of a liberal quantity of such calico, and if need be a slight string of evergreen festoonwork might be placed upon the drapery with pendant strings of both at suitable places. The lower part of the walls might be entirely covered with cloth if necessary—say for 6 feet up, which gives a warm and comfortable appearance; while the ceiling might be festooned over, or fanciful devices in ironwork covered with evergreens might be introduced there, as I suppose the ceiling to be white.

Flags may be worked-in with advantage, but they ought not to occupy too prominent a position; and if only ornamented

flags be used, do not let them be too large so as to conceal everything else. A number of flags arranged as a fan look well over a doorway, or at the end of a room; and a series of uniform-sized ones arranged on flagstuffs pointing from the sides inwards at an elevation of not less than 35° also look very well; but do not by any means cover the whole of the roof with them, as the eye likes to rest on some empty space, and musicians complain of the presence of flags marring their performances.

It is needless here entering into the subject of lighting public rooms of the description given above; but if temporary lights have to be adopted the objects that hold them will require covering in some way or other; and often an admixture of drapery and evergreens comes in good stead here. Any slender work done in evergreens may be performed with twigs of Irish Yew or some other small-leaved plant, Box being the next best. The dressing of the tin cups and sockets to a candlestand may be very well done with these two evergreens; but if only a board be used slung from the wall, it must be entirely concealed by drapery in the first instance, and that more or less ornamented with foliage or flowers. Makeshifts of many kinds are often enough used, and they answer the purpose very well.

The above refers entirely to such ornamental work as is done in-doors, as triumphal arches, &c. Similar decorations outside are more especially mechanical features, requiring a framework more or less substantial. These need not be gone into here. The nicety of workmanship necessary in the fastening of the evergreens in the interior is not wanted for them, large and bold lines being more required, accompanied with the stability necessary to withstand high winds and other casualties.

I hope that any one who discovers any new mode of using evergreens or other cheap material for giving a cheerful and pleasing effect to a room or suite of rooms will give the readers of THE JOURNAL OF HORTICULTURE the benefit of his discovery. Suggestions on this subject are often welcomed by those who, for the first time perhaps in their lifetime, are called on to ornament an assembly-room. Perhaps, too, some happy effect may be produced at a cheap rate by some mode of using the materials different from what is described above. The subject is certainly not of less importance than dinner-table decoration, which has received its meed of attention.—J. ROBSON.

ROYAL HORTICULTURAL SOCIETY.

REPORT OF THE COUNCIL TO THE ANNIVERSARY MEETING,
FEBRUARY 10, 1863.

THE first duty of the Council on meeting the Fellows on the present occasion is to congratulate them on the success which has attended the Society during the past season.

A reference to the balance sheet appended to this report will show that the receipts have largely exceeded those of the previous year.

While thankfully acknowledging this measure of success, the Council cannot but feel that had H.R.H. the deeply lamented Prince Consort, who laid the foundation of it, and to whom it is mainly due, been spared to the Society, results even much beyond this would have been achieved. A very large portion of the prosperity which the Society has enjoyed beyond its ordinary receipts is referable to the Great Exhibition. The interests of the two undertakings during the past year were closely linked together, the same causes which injured or benefited the one equally affecting the other. Had, therefore, the influence of His Royal Highness been spared to it, it cannot be doubted that the Council would now have had to present a report even more favourable than the present.

Out of the receipts during the year, amounting to £29,800, a sum of £8676 was received as the Society's share of the joint season tickets, a sum of £1125 from the various refreshment contractors for portions of the Society's premises let to them, and £5029 from the promenades, chiefly drawn on those days when the charge for admission from the Exhibition to the garden was sixpence.

The flower shows produced upwards of £5000, which is the largest amount that has ever been drawn by the Society from that source in any one year. Had it not been for the large number of joint-ticket-holders, this amount would of course have been still greater. The shows themselves were also of unparalleled excellence, the Council having determined that nothing should be spared to make them worthy of the Society,

and such as would leave a favourable impression on the numerous visitors from abroad. A statement is given in the appendix, showing the amounts received and the expenses disbursed at these shows, so far as the latter can be separated from the general expenses of the establishment.

The Council have also to report favourably on a more important portion of the financial resources of the Society—viz., that drawn from the subscriptions. The following comparative statement of the number of Fellows, and their rates of payment, as at 31st December, 1861, and 31st December, 1862, shows the increase during the course of the year—viz.,

	As at 31st Dec., 1861.		As at 31st Dec., 1862.	
	Payable in advance.	Retro- spectively.	Payable in advance.	Retro- spectively.
Fellows paying 1 guinea.....	...	10	7	3
" " 3 guineas.....	...	25	16	9
" " 2 " ".....	716	6	912	6
" " 4 " ".....	915	215	1307	80
Fellows who have compounded by paying 20 guineas.....	334	...	386	...
" " 40 " ".....	555	..	587	...
	2520	256	3215	98
	256		98	
	2776		3313	
			2776	
Increase	537	...

The above table shows the actual state of matters each year, at 31st December. But on taking deaths and resignations into account, it appears that 633 new Fellows have joined the Society since 31st December, 1861, and that there have been 55 deaths, and 41 resignations.

It will be seen from the above table that the recommendation of the Council in last year's report, that Fellows who paid retrospectively should change their retrospective payment into one in advance, has been well responded to—the number of retrospective subscribers having been reduced from 256 to 98. Many of those who are still in this position have no doubt continued so from inadvertence, and it is hoped that in another year the number may be still further reduced.

Through the consideration of the Fellows too, the transference of the period of payment from the 1st of May to 1st of January has been all but unanimously carried into effect.

As regards the expenditure, the unfinished state of the garden, together with the exceptional nature of the year, added to the fact that the previous season was equally exceptional from its being the opening year of the reconstituted Society, and from its only extending over eight instead of twelve months, prevent the receipts and expenditure of the two years being contrasted with each other, and the Council must confine themselves to treating the expenditure of each by itself.

The expenses of the publications of the Society are large, owing to the considerable number of Fellows; but the information contained in them is (the Council have every reason to believe) considered valuable by the Fellows at large. The Council, however, with the view of making it contribute to its own support, have resolved to allow advertisements to be received on horticultural and scientific subjects.

Mr. Weir, the plant-collector in South Brazil, has examined and reported on a district not much known, and when last heard from was on his way to explore new ground in the interior. Mr. Cooper, the plant-collector in South Africa, was sent out as an explorer at the private charges of Mr. Wilson Saunders, the Treasurer of the Society, who admitted it to a share of Mr. Cooper's collections on terms so liberal as to be almost gratuitous. Mr. Cooper explored the district of the Drachenberg Mountains, lying to the south-west of Natal, and found it, although in many parts barren, to contain a considerable number of plants of interest to the botanist, and some of much beauty, well worthy the attention of the horticulturist. The product of the labours of both these collectors have either already been distributed, or are about to be distributed among the Fellows by ballot.

The expenses of Chiswick have this year amounted to £2354, from which a sum of £435 may be deducted, which has been received for fruit sold and reimbursement of garden charges.

Upwards of 50,000 bedding-out plants have been reared at Chiswick last year for use at South Kensington. Further, it is to be noted that the Fellows have received large quantities (upwards of 3000 packages) of cuttings of Vines and other fruit-trees from this garden; that an unrivalled collection of fruit-trees is there maintained for the comparison and testing of all kinds of fruits; that the experiments and trials of the Fruit and Floral Committees are conducted there, and a large portion of the flower-seeds grown which are distributed amongst the Fellows. 2610 packets of valuable seeds, 11,000 plants, and 166 lots of bulbs have been distributed from these or other sources during the past year. In addition there have been distributed 1500 packages of seeds of vegetables, and a like number of packages of flower seeds.

The expenses of the garden at South Kensington have amounted to £6063. The details of which this is composed will be found in the appendix.

The expenses for promenades and exhibitions have largely repaid themselves, besides affording much gratification to the Fellows, and the Council have resolved to continue the promenades during the present season, twice a-week from 16th May to 1st August.

The Council have the satisfaction of informing the Fellows that the Commissioners of 1851, through the Expenses Committee, with whom rests on their behalf the control and regulation of the expenses of the Society, in the most liberal manner authorised the expenditure of a considerable amount of the receipts in the execution of works which strictly speaking belong to capital—a liberality which in the present year, when there is a surplus to the half of which the Commissioners are entitled as their share of profit, is equivalent to themselves paying the half of these expenses.

The Commissioners of 1851 have throughout shown the utmost desire to promote in every way within their power the completion of the garden. It is to them that the Society owes the beautiful façade of the refreshment-room. They have paved the upper arcades during the season, and lent, as above mentioned, valuable assistance towards the completion of the garden, its clothing and decoration—works which the Council have felt to be of pressing importance. As regards the decoration of the garden, the Council have been much assisted by the liberality of the Fellows, who have allowed their subscriptions, originally intended for the French fountains, to be applied in the purchase of works of art for the garden.

As regards the planting of the garden, the Council have, they trust, effected considerable improvements in it by the introduction of clumps of trees and shrubs. They have also provided a large supply of bulbs for its spring decoration, and they have to acknowledge the assistance received by presents from Her Majesty, and some of the Fellows.

A great deal, no doubt, still remains to be done, but so far as these objects are concerned, the work already executed justifies the Council in looking at their progress with satisfaction. It is otherwise, however, with a part of the garden less under their control; a portion of the arcades still remains unfinished, and in a measure neutralises the beneficial effects of other improvements. The completion of the arcades belongs to the Commissioners of 1851, and notwithstanding the reluctance which the Council have naturally felt to press a body who had dealt with them so liberally, they have considered themselves called upon to make a most urgent appeal to the Commissioners on this subject.

There still remain structural works pressing for completion which belong to the Society to execute; such as the council-room portico, steps in the middle walk, a western entrance, &c.

The Council regret to have to announce the retirement of Dr. Lindley from the Secretaryship, which he has held so long with honour to himself and benefit to the Society. Last year he tendered his resignation, but was induced to withdraw it at the solicitation of the Council, on the ground that as he had supported the Society during its period of depression, so he should remain as one of its officials until the next summer (1862) should have crowned his labours with success. He has now repeated his resignation, and the Council have most reluctantly felt bound to comply with his wish, and accept it. He has been for forty-one years an officer of the Society, and during that period, to use his own words, he "has endeavoured to the best of his ability to promote its true interests as a great English association for the advancement of horticultural knowledge, until, through many changes and some adversity, it has at length gained a position of high eminence, and may be regarded as standing on a secure foundation."

The Council need not repeat the arrangements for the coming season which have been already made public. The chief alteration on those of last year is the non-admission of the public to the garden except on fête days and promenades, a restriction by which they trust that the comfort and quiet enjoyment of their garden by the Fellows and their friends will be materially increased.

The Council cannot conclude this report without congratulating the Fellows on the continued interest the Queen takes in the Society and its proceedings. Constant reports of its progress have been furnished to Her Majesty throughout the season, and she has in various ways marked the interest she has taken in them.

DOES APOTHEME ENTER PLANTS?

YOUR correspondent says he is no worse than the writer in the *Times*, who wrote anonymously, and to whom his paper was a reply; but, after all, there are few, if any, who consider the *Times* immaculate in any way, and "can two blacks make a white?" Thomson's "Vegetable Chemistry," nor any other book, cannot prove to me or any other man, that apotheme never entered into the roots of plants, because it is a mere conjecture based upon a few imperfect experiments. A million analyses would give very uncertain data after all, in such a very intricate matter. How can we ever know that apotheme does not enter the roots and get instantly resolved into its elements, which as rapidly form new combinations of fluids? How can we ever hope to detect with accuracy such minute and instantaneous movements? and is it not presumption in any one to assert that a fact has been established on such crude evidence? I do not think it is far out of the way to say, that there is an irreverent way of searching into the mysteries of Nature, and that science prosecuted in such a fashion "is falsely so called."—WM. BAXTER SMITH.

["I return Mr. Smith's letter; and not feeling that either the writer in the *Times* or myself are necessarily 'black' because we write anonymously on a scientific subject, nor that I am guilty of 'irreverence' in believing that analytical chemistry detects truths, I retain my incognito, and believe in the accuracy of the published experiments of Prout, Robiquet, and others, rather than in an opinion founded upon no evidence at all. No one can object to Mr. Smith entertaining his own opinion, and I certainly shall not charge him with 'irreverence,' nor even with deficient logic, in preferring no experiments to a few. I regret, however, that Mr. Smith would not be convinced even by 'a million experiments,' because conviction in natural philosophy, contrary to a foregone conclusion, must with him be impossible, and Lord Bacon and others must have pointed out a wrong road to knowledge when they told us to try experiments, or, as he termed it, 'asking questions of Nature.'—J."]

VEGETABLE TERATOLOGY—ABNORMAL CALCEOLARIAS.

BY DR. MORREN, PROFESSOR OF BOTANY IN THE UNIVERSITY OF LIÈGE.

THE Abbé Van Oyen, professor of physical and natural sciences of St. Trond, sent me a collection of very remarkable Calceolarias, amongst which two forms of the greatest interest were carefully preserved. The Abbé truly observed that it was desirable not to forget those extremely rare cases in which Nature sometimes works, not in violation of her laws, but in deviation, so to speak, of her most common habits. These remarkable structures are indeed revelations, the interpretation of which ought not to be neglected.

M. Moquin-Tandon, in his classification of vegetable monstrosities, forms a class in which the deviation of the specific type is connected with the form. These deviations are of two kinds: they are either changed from one organ into another, and then they constitute *metamorphoses*, or they are alterations which, being irregular, become *deformations*; or, being regular, constitute *Pelorias*.

M. Van Oyen's pelorias of the Calceolaria were produced by some garden varieties of corymbosa, crossed first by pendula, the resulting varieties subsequently intermingled. An analogous form of peloria was seen in 1833 by M. de Chamisso, in the Calceolaria rugosa, and later by Guillemain. The specimen of M. Van Oyen differs from these, chiefly by its great size, colour,

and form: it forms the third example of the kind which has been recorded.

The Calceolaria is, as is known, a scrophulariaceous plant, having normally an equally divided four-parted calyx, and a hypogynous corolla formed of a very short tube, and a limb of two lips, the superior one short, truncated and rounded, entire; the inferior very large, prolonged in the form of a slipper, and concave. The flower is furnished with two stamens, inserted on the tube of the corolla, scarcely exerted; the anthers bilocular, the cells separate, divaricate, one often sterile. The ovary is bilocular; the placentas multi-ovuled; the style simple, the stigmata pointed. Such is the type of the genuine flower. The following is a description of the peloria of Van Oyen:—Two flowers alike normal grew to the right and left of the summit of the floral branch. This summit was itself terminated by a pelorised flower, which measured, not half an inch long, like that of Guillemain, but nearly 4 inches. It was not, as may be seen from the figure, a dwarf monster. The calyx was conformable to the normal flower. The corolla had the form of a

Rhenish wine-flask, much elongated, straight at both extremities, inflated at the middle, the part towards the summit being contracted like the neck of a bottle; the summit of the corolla itself was still further contracted, and tapered in the form of the mouthpiece of a flute, where it split in two oval openings. The corolla, when opened, presented no trace of stamens, only the pistil of regular form was placed at its base, and had its style curved to one side. The colour is not less remarkable: on the ordinary flowers of this variety of Calceolaria, the base is straw-colour, and there is a red tinge visible at the inside, the internal cuticle being coloured red; the inferior lip is coloured with light red, but here it is the outer skin that is coloured. Now, in this monstrosity the base of the corolla presented at first a yellow zone; then a broad red band in the interior, proceeding from the coloured part of the internal skin; then came a zone of pure yellow, and at the contracted part the outer skin was coloured with red; and at last the small narrow terminal beak was of a rich yellow.

The base of the bottle-shaped corolla, it therefore appears, represented the throat of the two-lipped normal corolla, and the conical end represented the inferior lip. The hypertrophy of the bottle-shaped corolla is evidently explained by the resorption of all the male organs. In the peloria of Guillemain, which only measured about half an inch, there was, however, also a complete absence of stamens. Is this absence the condition of the regularity of arrangement of the bilabiate flower of

Calceolarias? The three cases noticed would seem to establish this view. According to this state of things, this pelorisation would seem to be a disposition of parts in a regular form; for the Calceolaria, having the flower bilabiate and slippered, is irregular, and the bottle-shaped peloria is a regular form, with the exception of its extreme beak. Yet, if properly considered, the pelorisation is not a regular disposition of parts. Such an arrangement of a Calceolaria would consist of a central pistil, five stamens, a rotate corolla, with five lobes alternating with the stamens, and a calyx with five teeth alternating with the corolla. Then the Calceolaria would pass from the family of Scrophulariaceæ into that of Solanaceæ, and the flower would realise its regular type, its native beauty; for it cannot be denied that beauty results from symmetry, and symmetry is a disposition founded on regularity, or a harmonious relation of numbers, parts, and form. It is a remarkable law of Nature that families that are irregular may return by these monstrous forms to their regular families; while we never see a regular flower realise the structure of an irregular one.

The peloria of Van Oyen does not show the Calceolaria to return to the type of the Solanaceæ, but descends still lower, and realises a still stranger form and one which is opposed to nature—an anandrous form: consequently unfitted to perpetuate itself. In this respect it is a monster in the fullest sense of the term, but one full of instruction.

Another monstrosity, also sent me by M. Van Oyen, consisted in a growing-together of two corollas; this occurred along with normal regularity of the calyx. The corolla was bicalceiferous, having three stamens all fertile, one of which was placed at the junction of the two inferior lips: the ovary is normally conformable, and the calceiform lip was furnished with a lobe turning inwards. This form of abnormal development has not yet been recorded in morphological works. It is, I believe, a true junction of flowers, complicated by the resorption of the totality of the superior lip, by the non-development of the double calyx, and the resorption of one of the four stamens which should have been developed. This morphological form may, perhaps, some day lead to the determination of the real cause of synanthous developments.

DATURA WRIGHTII.

I BEG to say a few words upon the treatment of this plant, as I am sure it will fully repay any one for the little trouble its cultivation requires.

First of all let me observe that it is generally, in fact in all cases, except by Messrs. E. G. Henderson & Son, described as an annual, and as requiring out-door culture. This is quite a mistake, as it is a shrub requiring a cool greenhouse or conservatory to bring it to perfection.

Two years ago I obtained a packet of seed from Messrs. E. G. Henderson, St. John's Wood, and sowed in March in a gentle heat. As soon as the seedlings were large enough to handle I put them into thumb-pots, and potted them on as they required it in a rich loamy soil. By August I had them established in eight-inch pots with a very nice show of bloom. After blooming, about the first week in October, I left off watering, and allowed them to go to rest, placing them on dry shelves during the winter. Early in the year, about the latter part of February, I shook the mould off the tubers, trimmed them, and put them into pots smaller than those in which they bloomed, so as to allow of repotting if required. By May they required repotting, and I gave them their last shift, some in eight-inch pots and some in larger (those in the eight-inch pots bloomed most profusely); and, as soon as they began to grow again, watered well and frequently with liquid manure, of which they will imbibe a large

quantity, not forgetting a frequent syringing, not on the blooms, to keep down red spider.

During July, August, and September I had a magnificent show of bloom, some of them 7 inches long and 5½ inches across, trumpet-shaped, and of a clear white shaded off to the edges, which were of a delicate mauve. I am quite certain I had from eighty to a hundred blooms on a plant during the season, generally three or four open at one time, and giving-off a strong magnolia-like perfume.

Datura chlorantha recurvis has special mention in most catalogues, but I really must say I would not give it house-room, for the blooms cannot compare with those of *Wrightii*.—GEO. M. BURTON, Southtown, Great Yarmouth.

HARMONY OF COLOURS.

THE harmonies of colours are as follows:—The three primary colours—yellow, red, blue; the three secondary colours—orange, purple, green, formed of combinations of the primaries, thus—yellow and red, or orange; red and blue, or purple; blue and yellow, or green. Each primary requires its complementary secondary—that is, the eye when it sees a primary, as, for instance, yellow, requires the secondary colour which contains the other two primaries, red and blue—namely, purple.

Hence, it follows, that in decoration it is absolutely necessary that yellow should be balanced by purple, red by green, and blue by orange. The accompanying figure shows the circle of colours, the lines connecting the proper contrasting or complementary colours.

It is also to be noted that cold colours, or those containing blue, should be used in larger quantities than warm colours, or those containing no blue.—(*Irish Farmer's Gazette*.)

WHAT DESTROYS CROCUSES?

I SEE in the "Journal" of the 10th instant, W. W. Bennett complaining of his *Crocus*-borders being destroyed. I am sorry to say he is not alone in that misfortune. I have a walk upwards of a hundred yards long, with border on each side planted with *Crocuses*, *Snowdrops*, and other bulbs. The former have been destroyed to a great extent. On first noticing the evil I attributed it to field mice, and had one side-walk thickly covered with cuttings from Gooseberry bushes. The depredators soon evacuated that side, but attacked the other side with double force, which confirmed my opinion as to their being mice. I have caught some in traps. I hardly think sparrows could make such holes, as the ground is a very adhesive clay.

But permit me to state what I have often found to be the quickest remedy—that is, if Mr. Bennett is not, like myself, troubled with too many predatory animals. I take a small piece of butter, or any other greasy substance, mix it with a little arsenic, spread thinly over a piece of bread, and lay it at certain distances. I shall be glad to hear from any of your correspondents any other remedy.—R. HOLLIDAY, Gardener to J. Allison, Esq.

WEEDS ON WALKS.

I FULLY expected this query of yours as to the effects of the acid solution upon boots and shoes, as it was the one that immediately suggested itself to my mind on my first experiment. By taking the following precautions, however, I have never found any of the bad effects suggested.

I fix upon a fine evening after a dry day, and, beginning at one end of the path, water away, stepping backwards slowly, and avoiding splashing. The weeds being thirsty soon absorb the solution, and what little remains on the stones and gravel the night-dew washes off, so that next morning all danger to boots and shoes is over. I have now tried it many times (as I

had formerly grass-edgings, which from constantly sowing fresh seeds necessitated fresh applications), and have every reason to be satisfied with it.

Should the operator spill a little on his clothes a little ammonia, such as a pinch of smelling-salts in water, will make all right again.

It also exterminates worms. The watering-pot and pail must, of course, be well washed afterwards, and be kept well painted. —LEX.

THE SEASON IN CORNWALL.

WE have had so far an exceedingly mild winter in this county (Cornwall), and it may interest you, perhaps, to know how far our spring is advanced. Yellow Crocuses are in full flower, and have been for two or three weeks; Hyacinths are in very forward bud—two forward a great deal for security from frost; the blue Squill covers the ground with its starry blossoms. In fact, our borders are gay with the snow white *Iberis semperflorens* (at least, I believe that is the correct name of the pretty little perennial which the people call "Mountain of Light"), scarlet double Daisy, and yellow and purple Crocuses, arranged alternately, and all in full flower at this time. By the way, I have omitted the Snowdrop from the above list, which contributes in no small degree to the general gaiety of the border; and last, though far from being least in beauty, the bright blue Squill. Some *Humeas*, which have been out all the winter, look pretty well, though rather "leggy," and Scarlet *Geraniums*, *Calceolaria floribunda*, and all sorts of *Verbenas*, are looking strong and healthy, some against a south wall, others in the beds.—S. L. J., *Cornwall*.

PREVENTING THE GOOSEBERRY CATERPILLAR.

A NEIGHBOUR told me the other day, when talking about these pests, that in the month of March, on some damp morning he dusts the bushes all over, and beneath them, with soot. The bushes being damp the soot adheres to the wood, leaving a sooty smell, which the moths and caterpillars do not like. By these means he says he is never troubled with them. As it is so simple and within the reach of everybody, I, for one shall test the truth of the plan, leaving some bushes unscooted in the same bed. I hope others will try it. It would be a great boon to us if we could obtain some sure preventive.—G. HOLMES.

TREATMENT OF APRICOT TREES IN BLOOM.

I VENTURE to suggest that our veterans, Messrs. Rivers and Pearson, are both right, but have overlooked the very important fact of the influence of the atmosphere. Please to observe, that in showery weather, such as Mr. Pearson named as a fine time for setting the fruit, the barometer would be at 29.20, or thereabouts, and the air consequently light, so that the pollen would disperse easily; in fact, giving us the dry atmosphere required by Mr. Rivers. Should this solve the difficulty, I should hardly think you will consider your space wasted.—GEORGE BURETON.

CONIFERS IN IRELAND.

I FEEL great pleasure in giving my experience with regard to the *Pinuses* inquired about by Mr. Robson.

In so doing, perhaps, I cannot be more clear than by stating the dimensions of a few Silver Firs now standing quite adjacent to the Castle, and which, according to most reliable information, were planted about the year 1803, and at that time were very small, having been brought from Scotland by a Mr. Webb, landscape-gardener, in his travelling-bag. The height is taken from the ground to the top of the leaders; the girth, at 3 feet from the ground level.

GIRTH.				HEIGHT.			
1.	8	feet	3 inches.	66 feet 2 inches.
2.	3	"	4	70 "
3.	9	"	6	73 "
4.	7	"	4	67 "
5.	3	"	0	68 "
6.	9	"	3	75 "

These are fair specimens from among a considerable number growing singly, or in groups of not more than six in a group.

Chiefly surrounded by Oak and Sweet Chestnut, and under-cover for game, Larch, Spruce, and Scotch Fir have grown equally well.

With respect to the newer kinds, those here are of very recent planting. In looking over the growth of 1862, I find the leaders of several as follows.

<i>Pinus excelsa</i> ...	20 inches.	<i>Abies canadensis</i> ...	12 inches.
<i>insignis</i> ...	36 "	<i>Nordmanniana</i> ...	14 "
<i>austriaca</i> ...	34 "	<i>Wellingtonia gigantea</i> ...	22 "
<i>Abies Douglasi</i> ...	24 "	<i>Cupressus Lambertiana</i> ...	60 "

Cedrus, *Libocedrus*, *Thuja*, and *Taxus*, all do well in sheltered situations. Among all the Conifers, here and around here, I find that the south-west wind at this season of the year browns the leaves, causing a great check to the plants in spring, unless they are partially sheltered by other trees, or something, especially while young; while a breeze from the north appears to have very little effect upon them.

Perhaps I should state that the locality lies between two chains of mountains leading east and west, so that the wind comes very strong from the south-west.—GEORGE BECKETT, *Shanbally Clogheen, Ireland*.

GRAFTING DEODARS ON THE LARCH.

THERE was a mistake in the description of Woodstock, concerning a Deodar grafted on the Larch, which it is necessary to rectify. It was planted some thirty-seven years ago, and five years ago was nearly 34 feet in height. It grew somewhat spindly, was deficient in robustness, and shed its leaves partially in the autumn. On examining the roots they were found to be unhealthy, and a closer examination proved that the tree was grafted on the Larch. No improvement taking place, Col. Tighe at length ordered the tree to be cut down, and when the roots were grubbed-up they were found to be affected with a bad case of the larch rot. We say nothing on the theory of grafting, but the above case was misapprehended, and, therefore, we give this statement of the facts.—E. F.

PRUNING VINES.

I HAVE a vinery about 60 feet long by 14 feet wide containing at the warmest end Muscats, and at the cool end Black Hamburghs. The Vines are about six years old. For the last four years I have had fair average crops. Being desirous of keeping them back as long as possible, I have deferred pruning them, and the question now arises, How am I to prune them? The wood is well ripened and the thickness of one's little finger, but the eyes close at home are by no means bold. The fourth and fifth are very plump and evidently fruit-buds. By pruning down to the fifth eye the spurs soon become too long; but should I prune down to two eyes? I am afraid there would be little or no fruit, at least, if I am to believe that the small eyes are generally unfruitful. The Muscat eyes are bold throughout, and I prune short accordingly.—D. W.

[If your wood is well ripened you may safely prune back to the small buds. Everything depends on the ripening of the wood. A crop, however, is a better thing than any adherence to a system, and if there were any doubts we would leave a portion of the wood in the short-rod style. The prominent pods will be best ripened; but the small buds at the base, if fully ripened, will be equally fruitful and come strong if those before them are removed. Were we in your case and in any doubt, we would prune for a crop and leave plenty of wood; by stopping the shoots you can make the back buds break, and the shoots from these you can keep for next year's spurs. Your delaying the pruning will not at all serve your purpose in securing late Grapes—that must depend on keeping the Vines cool. If you have forced previously, the pruning should not be delayed, or you may have bleeding. When once a Vine is in leaf you may prune as you like, provided you do not take too much away at a time so as to weaken the energies of the plant.]

FEATHERED HELPS IN A GARDEN.

FOR want of a better phrase I thus designate a subject upon which some practical enlightenment will oblige me. I am led to it by the references to bantams in a garden, and especially by your own remark, that a particular sort does very little harm in a garden, which somewhat surprises me.

I presume that if poultry did not scratch and tear everything, they would do very much good by destroying insects of various sorts, and, I presume, that much good may be done by birds, judiciously chosen, in that way. Nothing like hand-picking in the main; but how many small insects are there that cannot be so dealt with—ants, for instance, which abound occasionally. If bantams could be kept without injuring growing crops they would be very handy. It is said that guinea fowls do not scratch, and are, therefore, good helps, as they swallow everything living. Then, again, some fancy a domesticated sea gull for the purpose, the hawk and the owl, too, are useful so far as mice; and, probably snails are concerned; and an observer of the habits of the birds, who has sat by the hour and watched starlings bring to their nest a slug or snail every three minutes for hours together, may well think it possible that a pair of those birds domesticated, and with a wing out, might be very useful. But practical gardeners must have some experience upon such a matter, for it is difficult to believe that the references to birds' habits scattered through books of natural history, have not been somehow gathered up for practical purposes by practical men. I have been greatly amused by seeing a pair of ducks hunt a piece of Box-border for snails or slugs, and was very much amused once by seeing a house sparrow chase, and with much difficulty catch, a butterfly, in Chancery Lane—a circumstance brought to my recollection by a suggestion in your pages that the house sparrow will not take insects. If the subject has not been already treated on in your paper, I fancy it is one upon which an article might be very usefully written.—H.

[We refrain from making any reply to this inquiry, because we should like to have all the information upon the subject which our readers will be kind enough to send us. Any one who has kept successfully a feathered help of any species in a garden, will oblige us much by sending particulars of the vermin it destroyed, what damage it did, whether it required a constant supply of water, and any other particulars necessary for its successful management.—EDS. J. or H.]

APPLE OF AMASSIA.

AMONGST the fruits exhibited at the Society's Great International Show in October, was an Apple bearing the name of the "Apple of Amassia," sent by Mr. Edward B. B. Barker, H.M. Consul at Samsoun.

It is fully medium size. Its general form is roundish, without angles; eye partially open in an evenly rounded depression; the stalk, of medium length and thickness, is deeply inserted in a regularly formed, rather narrow cavity. The skin is glossy, pale yellow on the shaded side, with a delicate blush next the sun. Flesh white, juicy, very sweet; but the specimens tried did not possess that rich brisk flavour which is considered requisite in what would be considered a good dessert Apple in this country. It is fit for use in October. In appearance it resembles the Mela Carla Apple, described and figured in "Horticultural Transactions," vol. vii., page 259, but the Apple of Amassia seems to ripen earlier.

In answer to inquiries addressed to him on the subject of this Apple, Mr. Barker has replied:—

"This variety has long been known at Amassia, but in no other town or district of Asia Minor, or anywhere else that I can learn.

"There are fourteen other varieties of Apples at Amassia, all inferior in every respect; proving that it does not owe its superiority to the climate or soil, although these last may be predisposing causes to its perfection.

"It is propagated by grafting; the fruit invariably the same. Young trees produce, however, finer fruit than the very old ones.

"It is always a standard at Amassia, and grows to the height of 15 feet.

"It is a great bearer, and a vigorous healthy tree.

"There is every reason to believe that this variety is indigenous to the town and gardens of Amassia; no one of the present generation remembers its having been introduced; and this is not a likely thing to have occurred in this part of the East. I have seen Apples from all the towns in Asia Minor and Syria, all very inferior. The moment I tasted it, I wrote and procured scions for grafts, and sent them at two different times to my gardener at Suedia, in Syria, and the more I know of this Apple the more I appreciate its qualities, which are these:—

"1, High colour; 2, Sweetness, with quite sufficient acidity

to be agreeable; 3, Plenty of juice when not over-ripe; 4, Fragrant perfume, in which most Apples are deficient; 5, Crispness without hardness, which enables it to travel to great distances without injury.

"It flowers and ripens at the same time as other Apples at Amassia, flowering in April and ripening in September and October; and would probably do the same in England.

"In regard to the name of this variety, it is called at Amassia Muskett or Musk Apple. Four years ago a Swiss merchant established at Amassia, sent a box of these Apples to Bâle in Switzerland, to his brother. At a meeting of the Pomological Society in that city, some were exhibited, and they were called Rose Apples of Asia (*Asiatischer Rosenapfel*.) It has been remarked that the flesh of some of these Apples, when ripe, is of a slight rose colour. I have not learnt of its having before or since been sent to Europe farther than to Constantinople, to which city about a hundred boxes are sent yearly, principally as presents. Its travelling so well is a remarkable feature. If I could have gathered the Apples here (Samsoun) at this port, they would have reached you in fine condition; but they had to travel on horseback (three days journey, about ninety miles) before they reached my hands, over very bad roads.

"Amassia is on land much elevated above the level of the sea, and consequently very cold in winter, and very hot in summer. The soil is calcareous, mixed with fine sand; exceedingly dry in summer, and the trees are watered by hydraulic wheels. The trees are never pruned nor manured; indeed no care whatever is taken of them, except watering them—an absolute necessity in the great heats of summer; but they would not require that in England.

"I will send you scions for grafting, so as to be in England in February or March next, by two expeditions—by steamer from Constantinople *via* Liverpool, by sea, and by the overland route, *via* Vienna, through the Foreign Office, by the messenger. They will be cut in January, during the coldest weather, so as to insure their freshness till May.

"I shall be very happy at all times to be able to give you any other information, if required, having inherited from my late father, John Barker, Esq., a great taste for horticulture, and having had some little experience in these eastern climates."

So far as beauty is concerned, the Apples exhibited at the Show in October bore out all Mr. Barker's encomiums, but the taste had been deteriorated by keeping and carriage. It had become too sweet, and the Apple had lost the crispness of which he speaks. But if the grafts which he promises prosper, we shall by-and-by have an opportunity of testing its value more fairly.—(*Proceedings of the Royal Horticultural Society*.)

WORK FOR THE WEEK.

KITCHEN GARDEN.

TAKE advantage of dry days to stir the surface of the ground among growing crops, and to keep down weeds. *Cabbage*, sow early sorts and a few Red on a warm border. *Carrots*, make a sowing of Early Horn. *Cauliflower*, make a fresh sowing in a frame, and prick out those already up. *Celery*, another sowing may now be made in heat. *Dwarf Kidney Beans*, sow a few Early White, Negro, or Dun-coloured in boxes for planting-out. *Lettuce*, sow Cos, when required, in warm situations. The beds to be looked over and blanks made good, after which they should receive a careful hoeing, not too deep, and have ashes, sharp sand, or sawdust strewn thickly among their stems. A similar application to the stems of Peas and Beans will be some protection from the attacks of slugs. *Onions*, take advantage of the first fine day with the ground in working-order to put in the main crop. Select a piece of land in good condition; and if the surface is not naturally firm, render it so before sowing by treading or rolling. *Parsnips*, prepare the ground by trenching or deep digging, and sow.

FLOWER GARDEN.

Proceed with Rose-pruning. The late mild weather has already advanced the buds of many sorts; an exception, however, may be made of Roses recently moved. Plant and lay Rhododendrons. Edgings required for flower-borders, such as Box, Thrift, &c., should at once be planted, and Box-edgings cut. Plant Pinks, Pansies, Wallflowers, Canterbury Bells, Foxgloves, Carnations, &c.

FRUIT GARDEN.

Proceed with pruning and nailing in favourable weather. If any planting still remain to be done, let it be performed as soon

as the ground is in a fit state for that purpose. Look to the Fig trees; prune and train those that require it, tying or bending the strong shoots down, which will induce them to push out a number of very short-jointed bearing shoots. Protect the blossom of wall-fruit trees. Fir boughs or straw ropes where Haythorn's hexagon netting or canvas cannot be obtained, should be employed to ward off the effects of frost. Clear away dead leaves from Strawberry plants.

STOVE.

Orchids will require an advance of heat, and unfailing attention in regard to atmospheric humidity. Look sharp after insects, the snails and slugs are very fond of the young tender buds at this period. Some Achimenes, Gloxinias, &c., to be set to work. Some of the Ipomæas, Echites, Pergularia, Stephanotis, &c., may be trimmed-in, disrooted if necessary, and plunged in a moderate bottom heat, using but little water until an active root-action takes place. Some of the Echites are easily rooted, and will endure a vast amount of drought.

GREENHOUSE AND CONSERVATORY.

Orange trees in tubs or pots to be carefully examined in order to ascertain whether or not their roots are in a healthy state, and those requiring more room should be shifted at once. When a shift cannot be conveniently given to large specimens, it is advisable to remove as much of the surface soil as can be done without injuring the roots, and replace it with a mixture of good turfy loam, ground bones, rotten cowdung, and sand. If they are infested with the scale or coccus family, apply with the engine clear soot water in a careful manner. Some of the hardwooded plants may now be propagated by cuttings where a gentle bottom heat can be kept up. Sow annuals for pot-blooming. Shift herbaceous Calceolarias when they fill their pots with roots, and keep them near the glass and well fumigated. Place Camellias past bloom in heat to make their growth. Shift Cinerarias freely, and fumigate often. Prune, pot, and start Fuchsias in a nice bottom heat if possible. Heaths to have plenty of air when not frosty, and shift any that have filled their pots with roots. Similar treatment is recommended for New Holland plants. Pelargoniums wanted to bloom early to be kept rather warm, and to be shifted into the pots in which they are to bloom. Keep those intended for late bloom closely stopped. Train the young shoots of climbers before they become entangled.

PITS AND FRAMES.

The plants in these structures will require to be carefully watched, as the warmth caused by the increased power of the sun in the daytime will most probably induce a too rapid progress at the expense of constitutional strength and vigour. It is, therefore, desirable to keep them as cool as may be found to be practicable, by allowing the free ingress of the external air. Anything like close confinement when the sun is shining on the pits and frames will certainly be injurious; at the same time, if the air is very keen and cutting, the lights must be opened on the side least exposed, and in such a manner as to prevent the cold draught from acting on the excited juices of the plants. Attend carefully to the stock of bedding plants, and get rooted cuttings potted-off as soon as they are in a fit state for that purpose, and encourage them with a gentle bottom heat and careful management to make quick growth, for after this there is no time to be lost with young stock. Sow Mignonette, Ten-week Stocks, Cockscombs, Balsams, and all tender and half-hardy annuals in heat.

W. KEANE.

DOINGS OF THE LAST WEEK.

FINE crispy mornings and bright days having come at length, regulated work accordingly, as far as possible, though necessity compelled us to do some work we would have preferred leaving to a rainy uncomfortable day. Wheeling in the hard mornings, turning soil during the day—that is, turning ridged-up ground topy-turvy, to give more of it the sweetening influence of the frost; charring heaps, and heating parings, scrapings, and other material, as covering, sufficiently hot to kill all the weeds, and burning as little even of Hollyhock-stalks as possible, as the charred, half-burned stems are much more valuable. The dry weather has been very useful for such work, and, therefore, much could be done with little labour.

KITCHEN GARDEN.

Put a little loose litter over Cauliflower hand-lights in the

coldest nights, turned broad leaves over Broccoli coming in, and had a little rough hay ready to place a handful over, if the frost got severe enough; sowed Carrots, Lettuce, and Cauliflower in a two-light box, to obtain just a little heat for them, the two latter to be pricked-out ultimately, to give room to the Carrots. Placed a foot of leaves over some Sea-kale in the open air, and that was pushing without more help than a cone of ashes. A good cone of ashes with these few leaves, will give an early cutting, without the bother of pots or boxes. The first are expensive affairs when there is not a handy man to wield the fork in looking for the heads. When there is little beside the ashes, it can all be done with the hand; or if a fork is used, the points will not have the chance of shivering the pots. The great point is to place no rank manure about such plants, or it will be no great credit at table to gardener or cook. Another matter is to cut it when from 4 to 6 inches in length, the elongated stems half a yard in length are little better than insipid juices. Took the first crops from the Mushroom-house, and put the plants in a cool shed, that they may be quite hardened before planting them again. This may be done at any time as respects the crowns with 3 or 4 inches attached, but the lesser roots cut up into pieces are as well stored in sand or dry earth until they begin to push. Placed some rotten rubbish-heap material over ground intended for Asparagus, as we could command nothing better; and when manure is scarce, after so far loosening the ground, it is well to keep the manurial matter near the surface, and add by top-dressing. Though Asparagus seed may be sown, and plantations made, we prefer planting Asparagus when it has sprung 2 inches, and keeping the roots moist, covered with moss or mat, so that no small fibres can be dried. Planted in that state of growth, and with that care, it is rarely that a single plant will fail.

Potted-off some more Dwarf Kidney Beans that were sown thickly in a box, putting five plants into a seven or eight-inch pot, using soil previously aired and warmed, and warm water for watering, the two last simple matters being more necessary to success than many people imagine. We have nothing to say against sowing the Beans in pots at once, where there is plenty of room, but that we are scarce of; and, therefore, by sowing in a box, we have two or three lights at liberty for several weeks, and, besides, the transplanting tends to make the plants more robust and fruitful. Potted Cucumbers and Melons in dung-and-leaf bed, prepared bed for Cucumbers, swept over Mushroom-beds, and cleared out as manure for flower-beds the Mushroom-beds that did such good service in the shed in the summer and autumn. We find that the droppings of horses are now so much wanted for giving a little extra heat to tree leaves, that our next bed for Mushrooms must consist chiefly of these tree leaves, with a few inches of dung on the surface.

FRUIT GARDEN.

The tomtits have commenced their visits since the frosty mornings; and we should like those who benevolently consider that killing one of the pretty little fellows occasionally is nothing but a horrid murder, to notice how soon, if unmolested, two or three of them will clear a Gooseberry-quarter for you, or leave a row of Pears little else than bare poles. However, were it not for such wholesale work we should be sorry to meddle with them, for we are well aware they do good as well as mischief.

If preserves for game are maintained as they are in some places, we prophesy that kitchen gardens close to them will have to be netted all over, if anything is to be expected from them, unless there are some battues every now and then for small birds, as well as for hares and pheasants. A slight net of wire stretched from wall to wall in an enclosed garden would not only be a new idea, but we are sure that under such circumstances of high preserving, it would also be the most economical in the end. In many places already it would be perfect folly to get a row of Peas up without protecting them with ridges of wire-netting; and what small birds do for Peas, partridges and pheasants will soon do for Broccoli, Cauliflowers, &c. We know that frequently in the early summer we might wish, and wish long enough, for nice dishes of young Peas to please visiting company, if we did not set a boy with tongue clappers and wooden clappers to keep the winged tribe at a little distance, as these sounds, discordant though they be, are not so shocking to nervous people as the report of a gun in a garden—in fact, the latter is quite out of place in a garden if it could be avoided. It is very trying to the patience when you expect to gather a superb dish of Peas or some first-rate Strawberries, to find that the birds have shelled the first

without your leave, and carried off or dug their bills into the best of the latter. Who will invent the most suitable cover-all for a garden, that will let plenty of heat and light through and keep out the smallest birds and the larger insects, just as we find it necessary to do so?

We may as well here allude to another matter growing out of this high-preserving question. In many gardens there is a difficulty in finding pea-stakes, and when found they seldom last good for more than a year, and then come in as fuel for fire-lighting. Many for want of them are obliged to grow low Peas, or allow them to run over the ground without stakes at all; but in such circumstances we believe there is a loss as respects quantity and quality. We have several inquiries on the subject, and see nothing better than iron supports with holes for wires to run through; but though these are used in some places, we feel certain that the person who manufactures an article that will be somewhat economical in price, and which will be easily moveable so as to be taken from and to a shed as desired, or, in other words, put up and taken down with little trouble, will command a large sale for the article. Strained wire fences are now getting common for espalier trees, Raspberries, and even Gooseberries and Currants, as when the two latter are trained flat fine fruit is not only obtained but the ground between can be cropped with other things.

We seem, however, to have lost sight of the birds. Well, as yet we have not done more than rough-prune Currants and Gooseberries, thinking it better to leave the final looking-over until we see how the birds and we agree as to the right quantity that shall be left to us. Meanwhile, to prevent their taking a delicious morsel, we mix-up a tub of rather thick wash, formed of soapuds and about equal parts of lime and soot, and double parts of clay and cowdung, which, when thoroughly blended and mixed, will pass easily through the nozzle of an old syringe. This, with a handful of salt to every eight gallons or so, is squirted over the bushes and the forwardest Pears, and sticks on pretty well by the help of the clay and the cowdung; and should continued rains come before the buds are safe we must just repeat the operation, and try thread, looking-glass, pieces of tin suspended, and all the rest of it. But so long as the buds are thus crusted they will hardly be touched by any bird that has any pretension to epicurism.

Strawberries in pots that are standing in beds and intended for forcing will need looking after, as, if they get too dry, the flower-buds will be apt to perish. We think a few of ours have done so, as the air has been very drying of late. If the frost should come much more severe, however, it will be advisable to cover them up at night after such watering.

Gave a little air early in the morning to Peach-house in bloom, increasing it gradually to mid-day, and waived a broad board quickly near the blossoms to disperse the fertilising pollen. Shut-up pretty early in the afternoon, so as to do with as little fire heat as possible. Temperature at night ranging from 45° to 50°; during the day with sun from 70° to 85°. Temperature of the first vinery breaking, 60° at night, air early, and heat allowed to rise with sun to 80° or 85°.

The most of the bedding plants are now moved from the Peach-house and from other places where heat is more required for other purposes. To find room for them we were forced to cut the remainder of the Grapes in the late vinery, keeping a good bit of the shoot with them, and sticking the shoots into moist soil in a moveable box, and covering the box with dry moss and clean paper. This suited our purpose best on the present occasion, though we would give the preference to the plan mentioned by Mr. Thomson of sticking the shoots into a beetroot, and allowing the bunch to hang over a shelf in a dry cool place.

Now, as to the Vines, it is right that mischances should be noted as well as successes. In cutting a young Vine we found that the stem came to us. Unfortunately, against our own wish on such a subject, the Vines are planted outside the house and brought in through a hole in the front wall, a little moss being placed round the stem in the hole. Now, just where the stem entered the hole it seemed to have been gnawed through—in fact, but for examining it carefully, it might have been supposed to be cut through. But the most curious thing is that not a vestige of the stem could be found from the cut or nibbled part, and no remains of nibbled wood, and though we searched carefully not a bit of the stem could be found, or even the larger roots, though we found the smaller ones in the border. A young Vine in an earlier house was found exactly in the same

way, not a vestige of stem from the cut part, but all gone, and no signs of nibbling, such as sawdust-like pieces of wood left. The whole of the stem seemed to be gone, and yet Grapes, which one would have thought more tempting, were left untouched. What made me conclude that mice were the destroyers was the following fact: A rather old Vine had not swelled its berries to the usual size in the autumn, and on examining the stem in the hole in the wall it bore traces of biting and injury for fully halfway round. Mr. Mouse must now be looked after; but, seeing the Grapes untouched, and seeds drying in the house quite safe, we never thought of looking after the stems that went through the wall. Do any of your readers know of a case of such wholesale destruction of young stems? Not a bit could we find, nor even a root of any size. Out of doors we found some young Apple trees that were fast going the same way. The nibbling had commenced at the surface of the ground, and when discovered the stems and most of the larger roots proceeding from the collar were nearly gone. In these cases, too, the stems farther up were not touched.

PLANTS, PROPAGATING, &c.

Much the same as last week. As soon as the late vinery is all thoroughly cleaned, we will fill every available spot with plants and keep them and Vines as cool as possible. For this purpose we will bring all the Vines near the front of the house that we may not only give plenty of air, but shade the Vines too if necessary.—R. F.

TRADE CATALOGUES RECEIVED.

Ambrose Verschaffelt, 50, Rue du Chaume, Ghent. *Spring Catalogue of Stove, Greenhouse, and Hardy Plants, &c.* 1863.
C. B. Saunders, Cæsarean Nurseries, St. Saviour's, Jersey. *General Catalogue of Fruit Trees. Catalogue of Trees and Shrubs. Select List of Cape Bulbs, Tuberous Roots, &c. List of Azaleas, Camellias, Dahlias, Fuchsias, Geraniums, &c.*

TO CORRESPONDENTS.

* * We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed *solely* to *The Editors of the "Journal of Horticulture, &c.,"* 162, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

PLANTING FLOWER-BEDS (*Cruceiferus*).—If we could make an exception in favour of any one, it should be in the case of so staunch a supporter; but we cannot make any exception. If you will arrange the plants in the beds, and send us an outline of the beds and how you propose to plant them, we will point out what we consider mistakes, if there are any. No one can plant beds the situation of which he has not seen.

PASTURE GRASSES FOR QUEENSLAND (*C. C.*).—We should send Crested Dog's-Tail, Hardish Fescue, Wood Meadow Grass, Evergreen Meadow Grass, White Clover, and Suckling Clover. Calico soaked in linseed oil would be liable to spontaneous combustion on the voyage. The only remedy would be to have it packed in tin-lined boxes, and soldered-down to exclude the air.

BUDDING PLUMS ON SLOES (*G. Carpenter*).—For five postage stamps you can have free by post from our office, "Fruit-Gardening for the Many." It contains directions for both grafting and budding. Plums grafted on sloe-stocks do not do well. Either sulphuric acid or caustic potash will render your refuse bones available as manure. The potash mode is preferable, being not so liable to cause injuries during the crumbling-down process.

ZINC-LINED BOXES, &c. (*A Subscriber*).—We have used zinc as a lining both for plant-boxes and water-tanks, without observing that it injured the plants.

ITALIAN GOURD SEED (*A Subscriber, Blackheath*).—We know of no reason why the plants should not do as well as other Gourds and Cucumbers, if ridged-out at the usual season.

ROSE ANNUAL (*W. H. M.*).—We have no information upon the subject.

DATE PALM PARASITE (*Date Palm*).—The little "seeds" you mention are the convex hardened bodies of the females of a small species of Coccus, covered with a thin pellicle of white waxy secretion, giving them a fungus-like appearance. Some of the females were shrivelled-up, having already deposited their eggs, but others were still filled with eggs, so that the tree must be cleared of them at once or it will be destroyed.—W.

PRUNING ROSES (M. H.).—If the weather continue mild it would be advisable to prune at once, but if frost set in, delaying vegetation, you had better wait until the frost be past. It is possible we may have more water yet than we have had, and it would be as well to wait and see the result. The progress of vegetation will be stopped if it continue cold, and the pruning could be done just before growth commences again.

VERONICA (S. L. J.).—Your specimen seems a variety of *V. Andersonii*, but they differ so much that we cannot positively say; and as they seed freely and sow themselves, and in mild autumn flower admirably, only varieties of unusual merit have of late years been distinguished by name. We expect it will do remarkably well in Cornwall. We know it to be quite at home in Jersey.

TROPEOLUM TUBEROSUM (Idem).—By all means occupy your hotbed with something better than these, which do pretty well against any dry wall. The more poor the soil the more likely they are to bloom, and we have sometimes planted them in flower-pots to check their growth. But it is generally late when they bloom, so that they have fallen into disrepute. In hot, dry seasons they bloom better; but such kinds as *Tropæolum pentaphyllum* and *T. brachyceras* have been more popular of late years.

TRITOMA SEEDLINGS (Idem).—You cannot do better than plant your seedlings amongst your American plants in bog earth, especially if the soil is not already fully occupied by the roots of *Rhododendrons*, &c. If the latter be the case, plant them elsewhere, as they ought to have a good depth of earth to themselves, and the bulbs will advance apace. Do not plant them too thickly.

IVY AND ROSES AGAINST A FENCE (A. R. H.).—Plant the Ivy out of pots 2 feet apart. You can buy it so growing 6 or 7 feet high. In front grow the Roses in large pots or butter-krinks buried in the border close to the fence. *Felicité perpetuelle*, *Myrianthes*, *Princess Maria*, and *Princess Louise* will do well for the purpose. Train the Ivy against the fence, and the Roses in front of the Ivy. Both the Ivy and the Roses will be benefited in summer by heavy waterings overhead from the garden engine, and by manure-waterings to the roots.

DECORATING PUBLIC ROOMS (J. O. G.).—You will find your inquiries answered in our paper of to-day by an article from Mr. Robson, which we think will meet your case, and that of others.

GRAFTING PEARS ON ASH STOCKS (J. W. P.).—Your friend has confounded the common Ash with the Mountain Ash. Pear scions unite freely with stocks of the latter, but they will not unite to the common Ash.

PLANTS FOR THE SEASIDE (A. A.).—We fear the starving character of the soil on your north-west coast will not suit many of our ordinary evergreens, but we have seen the *Laurestinus* and *Amorpha japonica* do well in the neighbourhood of Plymouth within reach of the spray. If, however, these will not do, try the *Tamarix* as you are advised, and *Pinus maritima*, and the various herbaceous plants which will endure the sea air, as *Thrift*, *Fennel*, *Evergreen Iberis*, *Alyssum*, and the like; but avoid the comifers, excepting the above. In deciduous trees the Sycamore stands as well as any. Perhaps some of our correspondents will give us their experience on coast vegetation.

DISTINGUISHING THE STOCKS OF FRUIT TREES (J. M. C.).—A man well versed in such matters might, perhaps, be able to tell you if he saw the trees; but he could not explain on paper the mode for you to do it, especially with young trees. Generally speaking, Free Stocks grow and thicken faster than the graft, while Quince and Paradise Stocks are the reverse; but this is not discernible in the young tree so well as in the more adult one. Cutting the bark of old trees of the kinds of stocks named, and comparing that with the young, will enable you to judge better than anything that can be written on the subject.

COTONEASTER MICROPHYLLA LOSING ITS LEAVES (P. M.).—It is difficult to account for your plant losing its leaves, as we have it in almost all situations, moist and dry, in sunshine and shade, yet it thrives in each. We find, however, that the leaves of *C. Simonsii*, a much stronger growing species, have fallen very much this winter, whereas *C. microphylla* is as densely clothed as ever and loaded with fruit of a rich rose colour. It would be well to ascertain if there be nothing pernicious in the soil it is growing in, as an escape of gas or a mixture of some poisonous chemical ingredients. Your plant, of which you enclosed a specimen fruit, is *Carotonia siligua*.

HEATING A MELON-PIT (W. D.).—If you meant to keep your present lining and a bed of tan inside, then you might heat your house sufficiently with two four-inch pipes. We should prefer the wall at the front to be close instead of pigeon-holed, and then you would have the heat without damp and steam. If you preferred having no tan, except perhaps a surfacing, and not to depend much or at all on the lining, then the best plan would be to have a small furnace and boiler at the west end, low enough for the top of the boiler to be below the lowest pipe in the house, and then take a flow and return for bottom heat and the same for top heat. This can be done and regulated by valves; or, as described the other week, take the flow to a cistern above the boiler, and from that regulate the flow for top and bottom as wanted.

PLANTING TUBEROUS-ROOTED TROPEOLUMS (M. A.).—We presume your *Tropæolums* are the small-flowering tuberous kinds. The shoot generally comes from the smaller end, but not always. If you just cover the bulbs with light soil, and give no water until they shoot, there can be no harm. It is quite as well to keep the tubers covered with soil in a shallow tray until they do shoot, and then pot them into their flowering-pots at once. Training is a matter of taste. Some like wire trellises flat or balloon shaped. We think nothing is more graceful than the top of a Larch tree, and the shoots entwined among its branches. Much care is necessary in training—in fact, when growing freely the shoots will want looking to every day, so that they be not permitted to grow in big wreaths and bundles. We have forgotten to say that sometimes the tubers will take a freak and rest for a year or two, and then come all right.

HEATING PIT FOR CAMELLIAS (A Learner near Bradford).—If your *Camellias* and *Azaleas* are healthy they will not need your hotbed of leaves and dung, but the heat from the pipes would be enough. However, if you think a little moist heat below would be advisable, be sure that the dung is sweet; and when you cover with ashes do not plunge the pots so much as half their depth. A sweet hotbed in such a place would be the thing for Melons, Cucumbers, and seeds of very tender plants, &c., but not so much for *Camellias*. Their small roots are easily injured with much bottom heat.

SOWING GLOXINIA TUBIFLORA (Subscriber).—Sow in hotbed. Sprinkle the seed on the surface, and then the least of white sand over it. Cover the pot with a piece of glass, and shade until the small dots of seedlings appear. Give them rich light soil.

SOWING ANAGALLIS (Idem).—Sow at any time before March in gentle heat. They should have sweet fresh loam and a little leaf mould.

SOWING BALSAMS (Idem).—If you have plenty of room and a cool place to take them to after their second potting you may also sow now; but if not, you will obtain better plants by deferring until April, and then, after the first potting, keeping them in a window-sill, or a cool greenhouse, or planting them out of doors. After the first potting the soil for *Balsams* can scarcely be too rich.

CHRYSAIDS (Nesci Brown).—It is the chrysaids of *Pieris rapae*, the small cabbage butterfly.

COCOA-NUT FIBRE DUST (Golden Fleecy).—Mix it with light loam in the proportion of one part by measure to two parts of loam.

SPOTTED GERANIUMS (P.).—You have a bad case of the spot. It is very difficult to eradicate. Your only chance is to cut off every affected leaf, and keep the plants drier with abundance of air and a little more heat. The chief causes of this disease are a close muggy atmosphere, roots too damp in winter, pots standing on a moist close bottom, as sand or ashes, and allowing the sun to strike on the foliage before it is dried by heat and air. By giving the plants the advantage of the opposite treatment you may succeed in making your plants all right, but some plants must inevitably be lost.

CROSS-BREEDING PELARGONIUMS (—).—Mr. Beaton is too unwell to reply to your queries at present. If you refer to the indices of our three last volumes you will find a mass of information on the subject, and the whole is epitomised in "The Science and Practice of Gardening," published at our office.

PILLAR-ROSE PRUNING (A Four-years Subscriber).—You may cut out some of the very gross shoots to the bottom, and leave the others as they are, as some Roses flower but at the tips. Yours planted only last year may be encouraged to grow until they occupy their allotted space, while by cutting out some of the gross shoots the bottom will be furnished.

BUDGING ROSES (Idem).—Use worsted string, or yarn very loosely twisted, to tie on the buds, and tie them gently, but at the same time sufficiently firm to close the opening. Matting or any flaxen tie bands expand and open in dry weather and become inconveniently tight when wet, and are consequently not so good. Articles in our previous Numbers have explained this.

PEACH TREES CRACKING AT THE COLLAR (Idem).—Some varieties are prone to this, but it does not seem to be attended with any bad consequences, as we have seen excellent fruit from a tree whose collar was entirely decayed, except a sort of spiral band that united the top with the root. If the top be healthy the stem is of less consequence, especially in an old tree. Attend to the instructions given by Mr. Fish and others from time to time, and success will crown your efforts.

SLUG EATING WORMS (Worcester).—Slugs will resort to and eat any dead animal matters. The live worm you saw them feeding upon must have been weakened by disease or accident, or it would have easily withered away.

NAMES OF PLANTS (W. O.).—1, *Chorozema varium*; 3, *Berberis Darwinii*. It is impossible to name plants from such scraps as the others are. (A. A.).—1, *Asplenium rutefolium*; 2, *A. splendens*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

DOTTINGS AT DEVIZES.

I SPENT a few hours at the Poultry Show lately held in this town. Few towns boast so convenient a spot for a Show—light, airy, and hitherto sufficiently large for the purpose.

There was a capital collection of poultry, but Game was pre-eminently at the head. A splendid lot of birds must have given the Judge some little trouble. Even with the arrangement of cock and one hen, it appears difficult to satisfy these pugnacious birds. I noticed especially that Mr. Fletcher's beautiful first-prize Brown Red bird treated his temporary partner in a shameful manner. In these classes it is absolutely necessary to make some greater provision against battles than was made at Devizes. A piece of wood 5 or 6 inches in width would prevent many squabbles if nailed on the outside of the divisions. It was a constant source of anxiety to the indefatigable Secretary.

I was delighted to see large Rose-combed Dorkings prizetakers. Though I no longer breed them, I am very pleased to see that you are urging breeders not to make them birds of feather. In Spanish an accident shifted the prizes. The third-prize cock of Mr. Rodbard was very nearly blind from the size of the white face. I do not think he could see with his right eye! In some unnoticed pens the trimmer seemed to have been at work!

Cochins were few but good. There was a splendid pen of Whites, and the Buff single cock was a magnificent bird.

Some of the Brahmas were good; but it is quite useless for breeders to show a pen with pea and single combs. Years ago they might have passed muster, now they must be uniform. I think I should have reversed the judgment in the single cock class.

Some Malays were there, most conspicuous by their ugliness. Bantams were first-rate, and mustered in large numbers; so,

also, were the East Indian Ducks, the entries of which were greater, if I mistake not, than any others!

The sweepstakes for single cocks brought some good birds, but is to my fancy a great mistake, and gives birds a value they have not really earned. Three classes contained only two birds each, whilst one, the Polish, had only a single representative. It appears to me a far better plan to let the cocks entered in the other classes be entered in a sweepstakes or not, according to the fancy of the owners. This would save expense to the owners in carriage, and I feel certain would add to the income of the Show, by bringing a greater number of birds into competition. Whilst at the single cocks, I may mention that some of the pens in which they were shown were much too small. I allude especially to the Brahmas and Malays, which could barely turn round. This not only injures the bird in constitution, but often so damages the plumage as to prevent any further prize-taking till the moult is over. The Committee would do well to alter this; and if they could make some of the pens for the larger-framed birds more commodious, it would be a move in the right direction.

Constant attention was paid to the wants of the occupants of pens. It struck me that the food was almost too plentiful; there certainly was no lack of it. The prizes were paid to any winners on their visiting the Show, or directly after by post. Here Devizes sets a very good example, which more experienced shows might imitate.—Y. B. A. Z.

DO ACORNS DISCOLOUR EGGS?

I HAVE a Silver-spangled Hamburgh pullet which laid in December last. The yolk of her eggs was black. I have two other Silver-spangled Hamburgh pullets and a half-bred pullet, a cross between Spanish and Dorking, which began to lay last month. The two Hamburgs also lay black eggs. The half-bred lays eggs of their natural colour.

I have other half-bred hens which laid eggs last summer and this winter of their natural colour. I am perplexed to find that now the half-bred pullet (Spanish and Dorking) is laying black-yolked eggs; and I am afraid that when the other half-bred hens lay again, their eggs will also be black-yolked.

The eggs are unsaleable, and we do not relish them ourselves. If you can give me any information as to cause, or if it is common for fowls to lay black-yolked eggs, I shall be very thankful.

I began to keep fowls last summer. They all run together with a half-bred young cock; they have a large park and wood to run over, where they have found, and do now, plenty of acorns. They have eaten a few holly berries, and are very fond of the ash-leap, and raw potato parings. Besides oaks and hollies there are a great many Scotch fir trees. The soil is sandy peat, sandy loam, sand rock, and gravel walks. I feed the fowls once a-day with whole barley, and occasionally with boiled potatoes. They are in good condition, and have what clear water they choose, sleeping in a hen-house at night.—H. H. D., Kent.

[We cannot answer your question. We have fowls that run where there are plenty of acorns, but we never see them pick one up. There is strong colouring matter in an acorn, and it is not unlikely they may have to do with it. Many birds lay eggs that have a dark shade on the surface of the yolk.]

BLACK BANTAMS AT DARLINGTON.

HAVING been a Bantam-breeder in my time, I have observed with some interest the controversy in your paper relative to the pen shown at Darlington, which I observed had the cock's legs washed, and, I was informed, on the spot "by order of the Judge, Mr. Hewitt."

Pure black legs are, amongst other things, characteristic points in Black Bantams—at least, so I have always understood; but so far as the controversy goes (upon which I do not say a word, but have my opinion), nothing to my mind elucidates Mr. Enoch Hutton's share in the blame, so much as his advertisement in your Journal of February 3rd, taken in conjunction with his famous letter of the 30th December last, in which he says the legs "were naturally a good dark colour." The awful mystery seems explained. The advertisement of the 3rd inst., says, not alone that he has "Black Bantams"

and "White," but that the eggs of the Blacks can be "warranted from pure black-legged birds only if required!" It is more than rumoured that he has a cross-breed, and it would be very extraordinary if he had not.—OBSERVER.

INSECT-FED HENS.

THERE is a person near Preston who keeps a great number of hens, and every day feeds them on some kind of insect that makes them lay—besides meal. I believe he breeds them from some old cheese, &c. All I know is that his hens lay regularly in the winter. Can you give me any information what these insects are, and how they are to be obtained?—W.

[We fancy the insect on which the fowls are fed is the gentle, or flesh-maggot. They are bred in immense quantities in Germany for this purpose; they are bred in pits, under glass, and are regularly fed and attended to. They will make your fowls lay; but coupling the objectionable nature of the food with the fact that forced laying spoils hens, and induces premature decrepitude, we think you will agree with us that "*Le jeu ne vaut pas la chandelle*."]]

YOUNG PIGEONS WITH OVERGROWN MANDIBLE.

I HAVE had lately a number of my young Pigeons with their upper mandible overgrown and hooked at the point. I cut one, but whether too much or too little I cannot say, it seemed rather to encourage its growth.—J. M. C.

[If you are breeding many birds with this deformity the fault lies with your breeding-stock; you had better introduce some fresh blood, mating your old Pigeons to the new comers. If the deformity is slight, a lump of old mortar made salt by soaking in salt and water will keep the beaks worn down at the points, as they will constantly be used in pecking it.]

PHEASANT AND SILVER PHEASANT HYBRID.

ONE of your correspondents doubts my assertion respecting the cross between the common Pheasant and the Silver Pheasant. Let the following be a reply to his doubt.

A gentleman having more Silver Pheasants than he could keep in confinement, turned a few out into his game-preserves. In the course of a year or two, several pied or mottled birds were seen in the woods. The next year the gamekeepers often met with more than a dozen of such birds at a time. I saw some of them, and they had a strange appearance compared with the old birds.

Nine years since at Bretton Poultry Show, there was exhibited, in a pen of Guinea Fowls, a hybrid between a Black Red Game cock and a Guinea hen. The head and shoulders and hackle were those of a Game pullet, the remainder of the bird was like a common Guinea hen. I had intended making some further inquiries after the fowl, but a death took place in our family the day after the Show. The bird was forgotten, and what became of it afterwards I do not know. About the same time at another of our local poultry shows, there was exhibited a pen of chickens the produce of a Bantam hen and Red Grouse, these I did not see.—S.

INTERNAL MOISTURE IN WOODEN HIVES.

I SHOULD be glad to know of some plan for keeping wooden hives dry from internal condensation, as in cold weather I find the moisture runs from their mouths.—B. W.

[The following communication from "A DEVONSHIRE BEE-KEEPER" describes a new mode of combating this difficulty. As, however, his plan appears to be applicable only to bar-hives and frame-hives, we would suggest, that in ordinary wooden boxes with fixed crown-boards nearly the same result might be obtained by boring a row of holes in the top, with, say, a three-quarter-inch bit, as near the back of the hive as possible, and covering them with a strip of perforated zinc.

"Having been greatly annoyed in former years by the injurious effects of internal moisture in wooden hives, and objecting to the usual plan of ventilating through a central aperture as likely to

be detrimental to the well-doing of the young brood, I have this winter tried a mode of ventilation which appears to have answered admirably, by keeping perfectly dry the interior of those hives to which it has been applied, whilst breeding seems in no way to have been affected by it.

"My apparatus consists of a square wooden frame an inch deep and of the same internal dimensions as the hive to which it is to be applied. A half-inch slit extending, nearly its full length, is made in one of the sides and covered with perforated zinc. This frame is inserted between the hive and its crown-board with the perforated slit at the back, and ventilates the whole hive when thus applied in the most complete manner without producing any current of cold air which is likely to prove injurious to the prosperity of the brood. As far as my experience extends at present, it has been completely successful in preventing the accumulation of moisture in the interior of wooden hives.—A DEVONSHIRE BEE-KEEPER."

FERTILE WORKERS—WOODBURY UNICOMB HIVE.

I LOOKED at my two artificial Ligurians on the 2nd of February. In No. 1, which I think has had no queen, and which had drones when I last looked, I again saw the drones, but no queen and no young brood. I then examined No. 2, and found the queen had begun to lay eggs; a piece about 2 inches square was sealed-up, others were in the grub state, and there were some new-laid eggs.

I did not look at the old hive; in fact, they terrify me, as they make an attack whenever I go near them. They are very strong. I will let No. 1 go on as it is. Do you think the bees (if it really is the workers that have been laying the eggs previously) will begin to do so again?

What is the best kind of glass hive for enabling one to see all their operations, and where could I obtain one? Where could I procure perforated zinc, which would allow the bees to pass through, and prevent drones and queens from doing so?

In taking off supers, or, in fact, doing anything to bees, I find that if I take them into a dark room with only a candle burning anything can be done to them, and they never offer to fly, if first given a few puffs of smoke from a lighted piece of cotton rag. It is a good plan, especially in winter, as it can be done any day. I did mine that way on the 2nd. I do not think mine have any chance of being able to get at any flowers this month. It has been a very stormy winter all through. Last night (February 4th) we had a perfect hurricane of wind and rain, with loud peals of thunder.—ALEX. SHEARER, *Yester Gardens*.

[It would really appear that the drone eggs in No. 1 must have been laid by fertile workers. If this be so, we can see no reason why they should not resume egg-laying as the season advances. We are glad to learn that you intend continuing the experiment, which is a very interesting one, and one which we hope will not escape the attention of our able correspondent Mr. J. Lowe.

The hive which will best meet your requirements is the

WOODBURY UNICOMB-HIVE,

in which you can readily place either No. 1 or any of your stocks which are in Woodbury-hives. It is fitted for the reception of

comb attached to bars; and, having outside venetians, or sun-blinds, instead of the usual opaque shutters, the bees work in the full light of day, and therefore continue their operations undisturbed when subjected to examination by the apiarian. It was a hive of this description tenanted by Ligurians, which excited so much admiration in Messrs. Neighbour's stall at the International Exhibition. These gentlemen manufacture and supply them at various prices, according to the kind of wood employed, and the degree of elaboration required in their workmanship.

We do not know if perforated zinc is manufactured of the description you require. Any ironmonger would probably make the inquiry for you. The perforations should be three-sixteenths of an inch in diameter.

We have often operated within doors when compelled to do so during winter, and consider it the best mode to adopt in very cold weather.]

THE COMMENCEMENT OF THE BEE SEASON.

It is recorded by Bonner the celebrated Scottish apiarian, that when the opening spring showed the first farina-laden bee enter his hives, he was so overwhelmed with joy that he made the day on which this occurred a regular holiday, and was in the habit of calling his family around him to celebrate over a glass of his home-brewed "metheglin," the happy event; and to "rejoice with him and his faithful servants at the return of the salutiferous season." Some of our modern apiarians, perhaps, will smile at old Bonner's practice, but the enthusiastic can easily appreciate the feelings which prompted these manifestations of pleasure on such an occasion. There are many circumstances which combine to produce such kindred emotions in all of us. The opening spring is a cheerful season. It is emblematic of youth, of promise, of hope. The long night of winter with its gloom and its darkness, is coming to a close; and spring, full of returning life, wakes up and resuscitates from their temporary slumbers ten thousand forms of animal and vegetable existences. Already the sweet little snowdrop, impatient of delay, has unfolded its pure white charms, and the crocus in some localities begins to expand its gaudy petals; and here and there along our garden-borders may be seen life pushing upwards to the light of heaven, while by the southern wall, and throughout the more sheltered grounds, the peeping buds of green proclaim that youthful nature is again reanimating each but-recently-withered-looking form, with signs of returning life. Beast, bird, insect and plant, all seem to rejoice in the first faint forecasts in the season's future; and the apiarian is not the last to hail with joyous welcome the evidences of all this, by seeing his little favourites shaking-off the dull lethargy of a long repose, and, bristling with renewed life, again commence the busy labours of another season.

I have often thought that it would be very interesting to know the exact periods when the variously-situated apiaries throughout the country commenced and closed the operations of the year. I have no doubt that the differences in point of time are considerable, arising principally from varieties of climate in the respective localities, and partly, no doubt, from the nature of the pasturage afforded. I imagine there may be a difference of some weeks in regard to the advancement of bees in spring, between the northern and southern parts of the United Kingdom. I observe from Mr. Woodbury's notice in No. 97 of this Journal, that so early as the 29th of January his hives were described as being in full activity, and that pollen was being freely carried into most of them. Such an announcement as this strikes us northerners with astonishment, and shows the advantageous start the apiarians in the southern parts of England have compared even with those situated like myself in the central division of Scotland, where we have at this season so much cold, wet, and wind as to preclude the bees altogether from showing themselves, even at the entrances to their hives. It is true that the present winter has been unusually mild; the thermometer averaging higher than ordinary. Notwithstanding, such has been the extraordinary character of this extraordinary winter—so unusually mild, yet withal wet and windy, that I have seldom or never seen a season so unpropitious in this respect—that in my apiary at least the bees have scarcely ever been permitted to venture abroad, but have been kept close prisoners for the most part, I should say, from October onwards to the present time; and there is not yet any apparent prospect of a change to the better.

It was but yesterday (the 4th February) that a storm, the nature and severity of which, is I believe unexampled at this season, passed over Edinburgh like a desolating scourge. Fortunately its duration was short—only half an hour; but during its continuance, the raging elements, thunder, lightning, rain and hail, waged a terrific war, inflicting considerable damage on property throughout the city, though fortunately unattended with any personal injury or loss of life. The thunder pealed forth with awful voice; the lightning flashed luridly athwart the opening sky with its broad bright streams of vivid blue; while the rain and hail fell in torrents, and the wind, blowing a perfect hurricane from the west, bellowed and roared with appalling fury. The scene was imposing and sublime in the extreme. Such an electric conflict seldom occurs at this season of the year; and though we might with reason have expected that the extraordinary weather which has ruled for some time back had at last reached its culminating-point, yet there is no apparent prospect of a speedy change in its peculiar character.

In ordinary seasons, if the weather is mild, we expect to see our bees begin pollen-gathering about the second week of February; but even then they are like angels' visits "few and far between," a solitary bee being seen now and then in this hive or that, entering at long intervals. Indeed it is only in March that we can say that our hives in this locality can be said to be in full activity, and carrying pollen freely, and to have really commenced the labours of the year. Accordingly, young bees do not generally appear till the beginning of that month.

I may mention that the earliest date I ever witnessed pollen-laden bees enter my hives was on the 28th of January, 1861, and the latest date on December 18th, 1857; but I again repeat that pollen-gathering is not actively commenced with us, even in early seasons, till about the beginning of March.—J. LOWE.

NEED THERE BE PROFITLESS BEES?

"T.," page 84, may be assured that with a little more circumspection his bees may be turned to a far better account. His wooden house should be closed in front, with the exception of some outlets for his bees. They ought to have 4 inches space in width, and 1 inch, or rather less, in height. On the outer side and beneath these there should be a ledge about 6 or 8 inches in length, and 3 inches in breadth for the bees to alight on. This landing-place should slope a little in front, in order that rain may freely run off. The inner side of this outlet for the bees should be perfectly even and square with the standing-board, so that a bee-box or any kind of hive, indeed, may, with a little contrivance, be exactly adapted to it, and made to fit so closely that not a single bee can escape at the junction into the house. The sides of the house should be well closed, and the back ought to have folding-doors that may open and close easily, and, at the same time, fit so perfectly that neither sun nor rain can penetrate.

Supposing that this house has been formed with four posts placed at the corners of the building, and that the legs of the same stand a foot or two above the ground; these legs ought to be kept constantly immersed in pans of water, formed either of lead, iron, or zinc, allowing a space of an inch or 2 inches between the latter and the legs, in order that the building may be kept constantly insulated. The great object of this insulation is to free the bees entirely from the approach of various enemies, which consume the honey almost as fast as the bees can collect it. These enemies are chiefly ants, millipedes, earwigs, and snails.

I have adopted this plan of insulation for several years, and have very seldom been troubled with the presence either of ants, millipedes, or snails, as they never can pass the watery moat if properly attended to. The latter acts as a complete barrier to them, and so it does, generally speaking, to earwigs; but these latter, bearing the motto "We fly by night," now and then will be found to trespass, and a single one may occasionally make good its landing in the fort, and, of course, require speedy punishment. I wish I could speak as effectually of means of expelling spiders. These adepts in cunning, as well as stratagem, overreach all my endeavours to bar them out. They will persevere in gaining a footing within the citadel, and, like military sappers and miners, carry on their art under the shade of night. Their webs, so beautiful to look on, and their ingenuity so truly perfect and mathematical, have been the admiration of naturalists of all ages, and their adaption of means to the end so

astonishing, that one cannot avoid exclaiming, How great is God in all things!

These spiders are seldom seen during the day—they hide themselves in some small crevice, and at nightfall spread their nets in front or near the mouth of the hives. I generally visit my hives early in the morning, and frequently find two or three of my dear little friends prisoners in the meshes of the nets. Then I resolve to visit them again at nightfall, and perchance I catch the delinquent *flagrante delicto*, and do not spare him; but frequently he is too quick for me, and either slips back into his corner or crevice, or as suddenly drops to the ground where, under the shade of darkness, he contrives to escape.

There is another enemy I would guard "T." against—namely, the large Tomtit or Ox-eye. He is a great devourer of bees in the winter and spring, but he is easily entrapped with a piece of fat; he generally has a companion, and both are readily thus caught.

I have said enough for the present of the enemies of bees. I will now turn to the friendly means whereby great encouragement may be given to the bees in spring. Whenever there is a garden at hand, let all the turnips not required for domestic use remain and run to seed; their blossoms will afford an abundance of farina—the chief pabulum or food of the larvæ in the cells. Even a small piece of ground might be appropriated to the purpose of planting a few dozen turnips purchased at some greengrocer's stall, with a portion of the green top remaining on them; these will readily shoot into large stalks, and every head will bear a blossom for the million of bees. Crocuses and snowdrops, the blossoms of gooseberry and currant trees, and the catkins of willows and nut trees, will likewise be available.

And lastly, having arranged the apiary and discussed the various foes and friends of bees, let me advise "T." to send to Messrs. Dean & Co., booksellers, London, and procure a little book on the entire subject, called the "English Bee-keeper," by "A COUNTRY CURATE," one of the most expert and intelligent apiarians of the present day. Let "T." read it twice over, and I am sure he will reap greater pleasure from his bees; and if he profit by the advice therein given, he will be able to treat his wife frequently with a present of most delicious honeycomb—the sweetest of all sweet things.—APIARIUS, *East Kent*.

NEW BOOK.

Popular Science Review. Edited by J. Samuelson. R. Hardwicke, 192, Piccadilly. Published quarterly.

We are not of the number who think it desirable to make all men philosophers; and fortunately, if all the world thought it desirable, the world would fail in realising its desire, for there are very few minds capable of deep research or profound reasoning, so there is no danger of our grooms poisoning our horses in experiments upon a universal food, nor of our coachmen upsetting us whilst designing practical tests of a carriage's centre of gravity. But we are of the number of those who would place a sixth sense within the reach of every one who chooses to acquire it, by popular explanations of everyday phenomena, and popular details of every modern discovery as it occurs.

Dr. Paris's little volume "Philosophy in Sport made Science in Earnest," is just the book we would put into a boy's hand, for he ought to know "why" his kite rises from the ground, and "why" his top spins; and every one is all the more respectable and respected for being able to explain "why" a dew appears upon the glass in a room and upon nothing else; "why" he prefers putting his foot upon a carpet rather than on a stone floor when he gets out of a bed during a cold morning; and "why" his razor mows off his beard more freely when it is hot than when it is cold.

So is every one more respectable and self-respected, and certainly has another source of pleasure opened to him, who understands the discoveries Science is every day revealing, without the labour, not to say the impossibility, of making himself a master of those sciences. Now, "The Popular Science Review" is just the publication to impart the desired information, saving the reader from the labour or impossibility. It is published quarterly, and in an amusing, readable, easily-understood form, keeps one "read-up" in the discoveries of the day. It embraces all the sciences, and as its best recommendation we will give a few

extracts beginning with one from "The Zoology of the Exhibition":—

"In the South Australian court was exhibited the Talegalla (with a representation of its nest), another of those characteristic birds with which these regions abound. Mr. Gould, who visited Australia with the ardent enthusiasm of a true ornithologist, has given us the best account of this bird, and places it among the Rasores (or domestic fowl tribe), and considers it as the Australian representative of the Turkey, which it equals in size.

"The Talegallas are gregarious and shy, rapidly running through the tangled brushwood. They utter a loud clucking noise as they stalk about the wood; and, like the ruffed Grouse of America, when perched on the branch of a tree, they will sit composedly to be shot at repeatedly till they are all brought down. The most wonderful part, however, of the history of this bird is its nest. It collects together a great heap of decaying vegetables as the place of deposit of its eggs; thus making a hotbed, arising from the decomposition of the collected matter, by the heat of which the young are hatched. Mr. Gould describes this heap as the result of several weeks' collection by the birds previously to their laying, and as varying in quantity from two or four cartloads, and of a perfectly pyramidal form. It appears to be the united work of many pairs of birds, and the same site is used by them for several successive years. The Talegalla uses its foot for this work, and when sufficient is accumulated, the eggs are deposited about a foot apart from each other, and buried about 2 feet deep, perfectly upright, with the large end upwards; and there they are left, as in an artificial incubator, till they are hatched, when, it appears, that the chicks force their way out without assistance. The natives collect as many as a bushel of eggs from a single mound, and they are much sought after on account of their delicious flavour and large size ($3\frac{1}{2}$ by $2\frac{1}{2}$ ins.). These remarkable statements of Mr. Gould have all been verified by the behaviour of some of these birds kept in confinement at the Zoological Gardens, Regent's Park, where this strange method of incubation has been observed in every particular."

"The Bower-birds (*Ptilonorhynchus holosericeus*) also keep up the character of Australia for its anomalous productions. These birds, with a plumage resembling black satin, are allied to the Crow, and are most singularly interesting on account of the bowers from which they take their name, and which they construct as follows:—With great skill and dexterity they weave a sort of arbour of twigs, fixing them below in a bed of various materials, and decorating their promenade, which is of various lengths, with shells, feathers, and other ornamental materials, which they collect from the country round. This bower has no connection with their nest, which is built later, but serves apparently as a playground, in which they sport, and play at hide-and-seek, bo-peep, and a variety of similar amusements, which we should hardly expect to have found their way into bird life. Their bower constantly occupies their attention. They arrange and re-arrange the materials every day, placing about it everything within their reach which may by any means serve as an ornament to it. The habits of these birds have also been observed in the Zoological Gardens."

From the botanical portion we will also give this extract:—

"*Hybrid Plants returning to their original species.*—M. Naudin, having fertilised plants of *Datura stramonium* with others of *D. tatula*, afterwards sowed the seeds produced by this union, and obtained hybrids of the first generation. These hybrids were isolated; and a few seeds coming to maturity, they were sown in April, 1862, and produced twenty-two plants of the second generation—viz., five of *Datura stramonium* in all its purity, whose fruits ripened and came to maturity; and nine typical plants of *Datura tatula*. The remainder were more or less of a hybrid character. M. Naudin believes that this third generation of the hybrids will turn completely to *D. tatula*. These remarkable facts, which demonstrate the fact of the spontaneous disappearance of fertile hybrids, without the intervention of a crossing with one or other of the parent species, appear to M. Naudin at present inexplicable."

"*Acclimatisation of Japanese Plants.*—M. Simon, writing from Japan, continues to recommend valuable plants for introduction into the Jardin d'Acclimatisation. The Hemp Palm (*Chamerops excelsa*) bears a temperature of 10° Fahrenheit, requiring no particular care. The stalk of each leaf is covered with filaments of various fineness, of which the coarsest are used for ropes, and the finer for nets. Another plant he speaks of is the Soja, a kind of Bean used by the Japanese for a condiment, and a very savoury adjunct to almost every Japanese dish.

"*The Sago Palm.*—Mr. Wallace, who has returned laden with valuable information from his Eastern travels, speaks of the Sago Palm as the staff of life to the inhabitants of New Guinea and the adjacent islands. He described it as a truly extraordinary sight to behold a whole tree trunk converted into human food, with as little labour as is required to convert corn into bread. A single good tree will produce six hundred pounds of sago cakes; and, with an expenditure of ten days' labour, a man may produce food sufficient for a year's consumption. The natural result is improvidence, laziness, degradation, and misery."

The following is a specimen of the "Microscopical" news:—

"*New method of preparing Alga, &c.*—Professor Reinicke recommends the following mixture as a dense, non-drying fluid, which prevents the shrinking of soft tissues—viz., alcohol (90°), 3 parts; water, 2 parts; glycerine, 1 part. The spirit being lighter and more limpid than water, compensates for the greater density of the glycerine. The preparation being placed on the glass slide in a drop of water, another drop of the above mixture is added to it, and it is placed aside, secure from dust, to evaporate till nearly all the fluid is gone. A second drop is then added, and so on, until a sufficient quantity of the non-drying material is left to cover the object. The glass cover should not be put on until all the evaporable part is gone. In this way M. Reinicke has succeeded in retaining the natural form, colour, and structure of delicate filamentous Alga, Fungi, and animalcules; and objects taken in the act of fission, conjugation, &c., remain unchanged, and as useful as living subjects."

We have many more extracts marked in Mechanics, Anatomy, Astronomy, Geology, Photography, &c., but we must close by stating that the pages of this Quarterly contain contributions from Dr. Fairbairn, Capt. Donnelly, Cuthbert Collingwood, Har-

land Coultas, Jabez Hogg, E. B. Truman, J. Breen, Mrs. Lankester and other favourably-known writers.

OUR LETTER BOX.

CAUTION.—Mr. Ridgway, Beawick Lodge, has obtained some Pigeons of a Cornish lady, and she cannot obtain the money for them. Another consignment of birds was detained by the station-master of the Great Northern Railway. Any one sending birds to a stranger, especially at Manchester, without prepayment, seems to us as if the senders were willing to run the risk of being cheated. We are weary of giving such cautions.

DUCKS' EGGS UNFERTILE (J. M.).—Your eggs are what are called clear eggs—i.e., they have no germ of life in them. The reason why they do not spoil is, that there is no development. The egg is not susceptible of change. When an egg is sat upon for a time, until a change has taken place, and there has been a beginning of life, and from some cause or other it is then neglected, the fetus perishes and becomes putrid. The egg is either added or it bursts under the hen. If your Ducks have no pond, provide one. If they have a pond, change the drake.

BROODY HEN (Nesci Brown).—We are afraid a wilful hen must have her way. All you can do is to shut her up in some place where there is nothing but the bare earth, no semblance of nest, no hay, straw, or anything of the sort; if on hard gravel so much the better. Many are sadly in want of broody hens.

DORKING COCKERELS FIGHTING (A. R. H.).—There are two methods of overcoming the difficulty you complain of. One is, to let the birds fight it out. Some object to that. Another and a more humane plan is to provide a linen bag, or an old pillow-case, tie it on a long rod, and when the birds are sparring at each other, buffet them both with it. Neither the first nor the second trial will be effectual; but if you will persevere for a time they will leave off fighting. If, however, the youngest cock has so little stomach for the fight that he runs instead of sparring, buffet the older one as he pursues him. If you have two yards, try to make them separate walks for a time. One cock would answer your purpose in June, but you must have two now. If every other plan fail, you must let the birds run on alternate days, or morning and afternoon; but it is bad to shut up a bird.

SELLING PHEASANTS AND PARTRIDGES (A Young Beginner).—You cannot sell game of any kind, either dead or alive, without a license, and then only during the seasons determined by law. Gold and Silver Pheasants are not considered game, and may be sold by any one and at any time.

WHITE SPANISH FOWLS (R. C.).—We have never believed the White Spanish were a pure and distinct breed. We believe them to be a sport. We have a hen this year has moulted nearly white. The faces should be white.

CATAREH IN FOWLS (Constant Subscriber).—Give your fowls plenty of bread steeped in strong beer. They are suffering from cold, and the effect of long-continued wet.

SWOLLEN RUMP GLAND (Kenton).—It is common in old birds for the oil-gland to become hard and ossified, as it were. There is no cure for this in an old bird. In a young one it is often only a temporary malady, and is cured by opening the top of the conduit. Cochins-China hens lay as well after as during the first year. They do not lay so early. Hens never lay so early as pullets.

BIRD PRIZES AT THE CRYSTAL PALACE (W. R.).—There are many points to be considered in such awards; and, even if we differed from the Judges in opinion, yet, as there is no suspicion of unfairness, no benefit could result from adverse criticism.

BIRD STUFFING (J. Hodson).—We cannot spare space for the details, and we recommend you to buy Mrs. Lee's little volume, entitled "Taxidermy," published by Messrs. Longman & Co.

PURCHASING BEEES (C. J. T.).—There appears no reason to doubt the superiority of the Ligurian species of honey bee, which you may obtain by applying to T. Woodbury, Esq., Mount Radford, Exeter. The common species you may probably be able to buy from some of the cottage bee-keepers in your own neighbourhood. The present is the best time to purchase. Prices vary much in different localities, but we should consider 20s. to 30s. a reasonable price for a good stock at this season.

DZIERZON (X.).—The name of this distinguished apiarian is pronounced Teertsion.

BEE-KEEPING (A Subscriber).—You cannot do better than purchase "Bee-keeping for the Many" (free by post from this office for 5d.), and adopt Payne's improved cottage-hive as therein described, with the exception of having it made a little deeper (say 8 or 9 inches instead of 7) than recommended by the author. We should advise you to lay out 20s. or 30s. in the purchase of a couple of prime swarms in May, a similar sum in hives, &c., and keep the balance for the possible purchase of sugar for feeding or other contingencies. You may also derive much information from the perusal of a series of articles, "How I became an Oxfordshire Bee-keeper," from the pen of our esteemed correspondent "UPWARDS AND ONWARDS," which appeared in the first volume of our new series, and may safely adopt his modification of Mr. Payne's hive if you prefer it.

CATCHING FIELD MICE (An Old Subscriber).—The holes mentioned by Mr. Brent may be baited with peas, wheat, acorns, or any seeds which such mice feed upon.

WRIGHT OF HAY IN A CURB YARD (A. S.).—It varies according to the age and size of the stack so much that in some stacks 12 cubic yards are required to be cut for a ton of hay, and in other larger and older stacks only 8 cubic yards. From what you state we conclude yours is of the latter description, for if 8 cubic yards yield a ton, then 1 cubic yard would yield 20 stones of 14 lb. to the stone, the quantity your men obtained.

TERRIER PUPS (A Constant Reader).—The progeny resulting from breeding in-and-in are always weakly and liable to disease and deformity. It is certainly possible so to breed as you are doing, for the toy terriers are all so raised. If the loss of hair can be repaired by medicine, it will be by the following ointment rubbed-in until dry, left on for three or four days, then to be washed off with soap and water, and a fresh dressing given. Train oil, half a pint; black sulphur, 1 oz.; white hellebore powder, half an ounce; oil of tar, half an ounce. Mix.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 49.1° and 31.9° respectively. The greatest heat, 68°, occurred on the 9th, in 1826; and the lowest cold, 15°, on the 4th, in 1852. During the period 169 days were fine, and on 83 rain fell.

APRICOT MANAGEMENT.

NOWING that, with the exception of the Fig, there is none of our ordinarily-cultivated fruits so little under the command of the gardener as the Apricot, I confess to some

misgivings in commencing an article on its management.

True, we often see Apricots do well, and sometimes remarkably so; but their success is often more to be ascribed to the peculiarities of the situation than to any particular manipulation to which they have been subject, and it may be very gravely asked (as will be done hereafter), if their fruitfulness in some places is not rather in spite of the treatment they receive, than in consequence of it. This is, perhaps, assuming more than many will admit; but, let us first consider the natural habits of the tree, its likings and dislikings, and other features about it, the study of which will, perhaps, bring more converts to my opinion than any reasoning.

I believe the native country of the Apricot to be the southern shores of the Black Sea, and, most likely, many of the countries bordering on the Mediterranean, so that it may be said to be naturalised in a latitude several degrees farther south than any part of the United Kingdom; but we are also told that travellers rarely find a good Apricot in Italy. This is very likely the case, although that country may be in the same parallel with the one where the Apricot is found in such perfection and profusion. Other circumstances besides latitude, determine the growth of plants. The Sugar Cane is on the same degree of latitude with that of perpetual snow in India, and something of the same kind may be the cause of the Apricot not thriving so well on the warm plains of Italy, as it does on the elevated regions of Asia Minor, and the mountain chains that stretch eastward from them. Thus, also, the Grapes of southern Europe, and of the upper Rhine, do not flourish in the hot plains of Western Africa or of India.

The Apricot flourishes and attains the proportions of a fair-sized timber tree in Armenia. From the snow-capt summits of that country's mountains cold streams are constantly descending, cooling in their descent the earth and its vegetation, the Apricot meeting the cold current about half way down the mountains' sides; and that there is something in the air of those elevated regions which is essential to the well-being of the Apricot there is no doubt, and that we have no mode of imitating this highly rarified air is equally clear.

One cause of our want of success in Apricot culture is thus revealed; and if we want an analogy for it, let us look to many of the Sikkim and Bhotan Rhododendrons,

No. 101.—VOL. IV., NEW SERIES.

which seem unwilling to thrive under the ordinary management they have received in our glass structures; and what else can account for their failure but the difference between our heavy, dull atmosphere, and the light, highly rarified air which surrounds them in their native habitats?

That strong currents of air are continually traversing the hilly defiles of the Apricot country, is testified by the travellers that have experienced them; and the gradual transitions from extreme cold to extreme heat are also what they are often strangers to against a wall in England, and have, perhaps, a little to do with failure. Soil has no little influence over success; but we have greater facilities for adapting this than we have for controlling the atmosphere, so that to the latter want of control I attribute our general want of success.

I would here inquire, Is the Apricot ever found in good condition near the seacoast? I have on more than one occasion given my opinion that the Peach and Nectarine are particularly at home in such places, more so, perhaps, than many hardy fruit trees and shrubs; but I cannot say I ever saw the Apricot in good condition there, and if it be so, there is another reason why atmospheric influences have much to do with success. The keen mountain air is widely different from that on the beach. If this be allowed, we will take another reason why Apricot trees are so often either unfruitful or so unsatisfactory.

The experienced plantsman of the present day knows full well that no amount of skill on his part can make all his plants have the nice bushy appearance that some have. No amount of cutting, however well done, can make the Poinsettia or the Euphorbia jacquiniæflora such nice bushy plants as Heaths, Azaleas, and many others. The knife may be used until the plant perishes under the punishment, and yet without becoming what the pruner makes the others. So, in like manner, the Apricot is, in many cases, ruined by the knife, for, like the Cherry, Portugal Laurel, and some other things, it will live and endure such mutilations as go by the name of prunings; yet its doing so is due to other favourable circumstances that prevent its dying rather than to the pruning (so called) suiting it. I admit that, planted against a wall, this cutting to shape cannot be done without; but it is owing to this cutting that I attribute in a great measure so many branches dying off, as well as the gumming, cankering, and other diseases which follow, or rather precede the sudden throwing-off of branches so commonly met with. Observe that I do not attribute those sudden paralytic affections entirely to the knife, but to that cause in conjunction with others.

I am far from certain that I am right in supposing that the age and worn-out constitution of many of the varieties now in cultivation may be a cause of failure. But as old varieties of Apples have ceased to be any longer healthy, why should not Apricots be liable to the same fatality? To those intending to plant, I would say, By all means try the new kinds, if they are recommended with confidence by those who have grown them; but some

No. 753.—VOL. XXIX., OLD SERIES.

old favourite names are so tempting that we are liable to prefer them rather than risk accepting a stranger whose antecedents are unknown.

Let us now turn to the causes most likely to produce good results amongst us, and examine into the conditions in which Apricot trees are really found to do well.

In the first place, let us consider the soil as one of the main adjuncts to success. Naturally, the tree grows in the stiff, moist earth of mountain regions; in confirmation of this, I may mention that the best wall of Apricots I know of is at Lord Verulam's, in Hert's, Mr. Bogue, the intelligent gardener there, telling me that although they did remarkably well, he has never been so successful with Peaches—in fact, Peach trees had done very badly. The soil there is a stiff loam retentive of water, and the situation an elevated one for the district. The trees were trained in the ordinary fan-shape, and did well, producing fruit in all seasons, excepting those adverse ones, when other causes of failure might be traced. The aspect, I believe, was an eastern one, but some on an opposite aspect did well also, while no aspect seemed to coax the Peach into a like healthy, good-bearing condition.

In contrast with this we now and then find the Apricot do very well against the end of a cottage, but certainly more generally so when the ground is not too light.

I once met with an Apricot tree planted against the sunny side of a low miserable-looking cottage on a common, and from the appearance of the tree some attempt had been made when it was young to confine it to the wall, and possibly some persevering knifeman would have kept it there as long as it lived; but whether from neglect, change of occupants, or other cause, the tree had been allowed to take its own course, and quickly was not only above the eaves, but reached above the chimney-top. The growth was not without fruit either, for I was told it produced good crops in most years, but that the fruit was smaller than the same kind against walls. The situation was anything but an inviting one. A bleak waste was to the north of it, and no shelter of any kind near; and as excellent bricks were made a very short distance off, the character of the soil may be thence understood.

I firmly believe that in a situation like that, with shelter from cold biting winds at some little distance, the Apricot might be grown to tolerable perfection as an open standard, without any of the pruning or treatment which has advanced into the character of a science with other trees. I believe there are some orchards so planted with Apricots; but they are far from numerous, and none have come under my notice.

As to the position for the Apricot in the gardens of those occupying favourable positions in the south of England, I believe a north wall is not at all an unsuitable situation. This is more especially advisable in dry situations, and where the soil differs widely from that recommended as the favourite one for the Apricot. That a south aspect is not required by this fruit in places south of the Thames I firmly believe.

Other considerations as well as aspect operate on the result; but so long as pruning must be done we must expect the uncertainty now so common, and against walls trees must be pruned. Whether doing this operation entirely in summer, as with the Fig, may produce the best result is more than I can say; but I should like to hear the opinions of others who may have had more experience in summer-pruning only. My own practice, like that of many others, has united summer and winter pruning.

Of the Apricot as a house fruit I have but little hopes. The first time I ever saw it tried was in 1829, and that was a failure. Now and then attempts to work it on the Peach under glass have been tried at various times at places where I have been, but with no better result; and the recent failure to grow it in an orchard-house, recorded in this Journal, is a confirmation of my views—that a tree occupying so elevated a position, and exposed to the never-ceasing currents of air passing through its branches, can hardly submit to the cramped-up condition of both top and root it is subjected to while in an orchard-house.

I may conclude by saying that I believe the Apricot tree dislikes a confined air, a light soil, and a knife; and that its blossoms are amongst the hardiest we have; but that the young fruit, long after being set, and, in fact, swelling, is liable not only to injury but destruction from frost is also certain. Shelters, therefore, that will take off and put on are better than stationary shelters for protecting this tree in spring; and these shelters

ought not to be too early removed, as our late frosts must be very hurtful to a tree so forward as the Apricot is by the 1st of May.
J. ROBSON.

THE ROYAL HORTICULTURAL SOCIETY'S FIRST SPRING SHOW.

THIS was held on the 25th ult., and, the weather having proved extremely fine, there was a tolerably good attendance of visitors, notwithstanding the unfavourable concurrence of a levee on the same day.

The place selected for the Exhibition was, on this occasion, the portion of the ground floor of the International Exhibition building formerly occupied as M. Veillard's refreshment-room, along each side of which were arranged masses of Hyacinths, Tulips, Crocuses, and forced flowers, making a very effective display considering the early period of the year.

Class 1 was for 12 distinct kinds of Hyacinths and for nurserymen only. Here there were but two competitors—Messrs. Cutbush & Son, of Highgate, and Mr. W. Paul, of Waltham Cross; and the collections of both, as well in this as in other classes, were worthy of the reputation which these gentlemen enjoy. Messrs. Cutbush took the first prize, the sorts being Double Blue, Garrick; Single Reds, Macaulay, Princesse Clothilde, pink striped, and Von Schiller; Single Whites, Grandeur à Merveille, Mirandoline, and Snowball, with very large finely-formed bells; Single Blues, Baron von Tuyl and Grand Lilas; Single Black, General Havelock; and Single Yellow, Ida.

Mr. W. Paul, who was second, had Single Reds, Howard, Princesse Clothilde, and Solfaterre, the latter very fine; Single Whites, Grandeur à Merveille and Queen of the Netherlands; Single Blues, Baron von Tuyl, Charles Dickens, Grand Lilas, Marie, and Mimosa; Single Black, General Havelock; and Double Red, Lord Wellington.

In the next class, 12 Hyacinths of six kinds, the prizes were offered by Mr. James Cutbush; and Mr. Carr, gardener to W. B. Noakes, Esq., Highgate, was first with Single Blues, Baron von Tuyl, Charles Dickens, and Grand Lilas; Single Reds, Madame Hodgson, Von Schiller, Princesse Clothilde, La Dame du Lac, and Howard; Single Whites, Mont Blanc, Alba Maxima, and Grandeur à Merveille; and Double Blue, Garrick. This collection included several very fine spikes, and the bells were large without being too loosely arranged on the stem.

The second prize was taken by Mr. Taylor, gardener to C. A. Hanbury, Esq., East Barnet, who had also some large and well-grown flowers. This collection consisted of Single Reds, Cosmos, La Dame du Lac, and Macaulay; Single Blues, Couronne de Celle, Orondates, and Mimosa; Single Whites, Mont Blanc and Grandeur à Merveille; Double Blues, Garrick, Laurens Koster, and Van Speyk; and Double Red, Duke of Wellington.

The Tulips formed a most brilliant display, especially the collection of 50 shown by Mr. Cutbush in the Miscellaneous Class, and for which he received a first prize. He likewise obtained a similar award in Class 3, which was for 12 pots of six kinds. Those which he exhibited here were Vermilion Brilliant, Rouge Luisante, Couleur Cardinal, Keizerkroon, yellow and red; Proserpine, a rich rose; and Fabiola, rosy violet and white. The only other exhibitor was Mr. W. Paul, who had likewise a very fine display, which well deserved the second prize which was awarded for it. Among the kinds which he exhibited were Keizerkroon, Coligny, Le Matelas (a fine deep rose), Bakhuizen, and Pieter d'Hooge.

In the Amateurs' Class, for 12 pots of four kinds, Mr. Young, gardener to W. R. Barclay, Esq., Highgate, was first with some fine pots of Tournesol, Standard Royal, Scarlet Duc Van Thol, and White Pottebakker. Mr. Carr, who was second, had the same kinds, with the exception of Couleur Cardinal instead of Standard Royal; and Mr. Blogg, gardener to J. P. Gasiot, Esq., Clapham Common, was third with Gloria Solis, White Pottebakker, Royal Standard, and Tournesol.

Collections of Crocuses were shown in Class 5 by Messrs. Cutbush & Son and Mr. W. Paul. The former received the first, the latter the second prize; and in each case the competitor made an extensive and very attractive display. Among Messrs. Cutbush's flowers were Jeanne d'Arc, Lina, and Calypso, white; New Giant, yellow; Sulphureus; and a great variety of blue, lilac, purple, and striped kinds, such as Sir Walter Scott, David Rizzio, Prince Albert, Ne Plus Ultra, La Majestouse, Lilaceous

Superbus, Albion, Versicolor, &c. Mr. Paul had David Rizzio, Sir Walter Scott, Sir John Franklin, Argus, Prince Albert, Marie d'Ecosse, Cloth of Gold, Large Yellow, Albion, Amazon, and Arabella.

The only other collection of Crocuses was in the Amateurs' Class, which was limited to 12 pots, and this came from Mr. Blogg, who had fine examples of David Rizzio, Prince Albert, Sir W. Scott, Lord Palmerston, Ne Plus Ultra, Albion, and Mammoth.

Of Forced Flowers a fine collection came from Messrs. Veitch, comprising Indian Azaleas covered with bloom, *Andromeda floribunda*, *Wistaria sinensis*, double-flowering Peach, Persian Lilac, *Dielytra spectabilis*, Lily of the Valley, *Amaryllis*, a small Orange tree, a white Ribes, *Rhododendron fragrans*, and some Hyacinths.

Messrs. Cutbush's collection, which won the second prize, contained several very nice Azaleas and Epacrises—*Rhododendron cawthraense*, *Kalmia latifolia*, Persian Lilac, *Polygonatum multiflorum*, *Dielytra*, *Amaryllis*, *Tournefortia* and *Rex Rubrorum Tulips*.

No collections of Forced Flowers were exhibited by amateurs; and in the classes for *Amaryllis*, Epacrises, Acacias, and Geraniums, there was likewise no competition.

Lilies of the Valley were exhibited by Messrs. Veitch, and Mr. Salter, of Hammersmith, who stood respectively first and second; and of Chinese Primulas there were several collections, the prizes going to Mr. Taylor, Mr. Todman, gardener to R. Hudson, Esq., Clapham Common, Mr. Blogg, and Mr. Cutbush, who also received a second for double Primroses.

In the Miscellaneous Class, first prizes were awarded to Mr. W. Paul, and Messrs. Cutbush, for collections of 50 Hyacinths. These occupied a stage by themselves at the end of the room, and as specimens of culture were well worthy of the distinction which they received. Messrs. Cutbush also received a similar award for a collection of 50 Tulips, which afforded a most brilliant display, red and yellow being the predominant colours. The following are the names of the principal varieties:—*Alba regalis*, *Belle Alliance*, *Berangaria*, *Bizard Pronkert*, *Cardinal*, *Cardinal's Gold*, *Ceise Primo*, *Comte de Vergennes*, *Couronne Pourpre*, *Cramoisie*, *Duchesse de Parma*, *Duc d'Arenberg*, *Duc d'Holstein*, *Epaminondas*, *Grootmeester*, *Marquis de Westerde*, *Monument*, *Rouge Luisante*, *Superintendent*, *Standard Royal*, and *Yellow Prince*.

From Messrs. Veitch came a miscellaneous collection of flowering plants, which consisted of Azaleas of various kinds, handsome bushes of *Eriostemon nerifolium* and *densifolium*, a fine *Cypripedium villosum*, *Imantophyllum miniatum*, *Amaryllis*, *Boronia pinnata*, *Chorozema ilicifolia*, a beautiful little *Rhododendron javanicum*, and some other plants. To this a first prize was also given; and Mr. Bull, of Chelsea, was awarded a second for a collection of new and rare plants, among which were *Hippomane longifolia*, *Cordylina indivisa*, *Araucaria Cunninghamii glauca*, *Dracæna gracilis*, a fine plant of *Cibotium princeps*, the curious *Agave filifera*, *Anthurium leuconervum*, and other interesting plants.

Equal third prizes were given to Mr. W. Paul and Messrs. F. & A. Smith, of Dulwich: to the former for a box of beautiful cut blooms of Camellias, and to the latter for six stove plants, consisting of *Croton variegatum*, *Ananasia sativa variegata*, *Cyanophyllum speciosum*, *Cyperus alternifolius variegatus*, *Sphaerostema marmorata*, and *Platynerium grande*. The same firm also contributed greenhouse plants, a miscellaneous collection of flowering and foliage plants, the pretty *Eriocnema marmorea*, *Hemerocallis elegans foliis variegatis*, the half-green half-white leaves of which showed to great advantage; also, several varieties of Cyclamens; and Mr. Todman had an extra prize for three fine pots of Roses—*Madame Willermoz*, *Géant des Batailles*, and *Jules Margottin*.

A box of the lovely rosy purple bracts of *Bougainvillea speciosa* came from Mr. Wainwright, gardener to W. C. Thornhill, Esq., Kettering, and excited much admiration on the part of the ladies. Some beautifully executed artificial flowers were also exhibited by Mrs. James Stoddart, of Victoria Station, Pimlico. These are formed of the delicate Chinese rice-paper, and represented with wonderful accuracy the flowers from which they are copied. On the present occasion they were arranged on opaque glass stands as dinner-table decorations, the upper portion of the stand being filled with Roses, Camellias, &c., whilst *Convolvulus* or Ferns twined round the base and stem, the whole having a light and elegant appearance.

FLORAL COMMITTEE.—A Meeting of the Floral Committee was held in the morning, and the plants brought forward for their consideration formed a part of the Exhibition.

Mr. Bull, of Chelsea, had *Trichomanes anceps*, a very handsome species, for which he received a first-class certificate; and a similar award was given for *Yucca lineata lutea*, the foliage of which was dark green, with a broad yellow band running down the centre of each leaf. *Yucca Stokesii* had leaves with yellowish-white variegations, but its appearance was not handsome. In *Yucca quadricolor* was another variegated kind; the leaves were striped with red at the base, becoming yellow towards the point, and white in the old leaves.

Mr. Bull had also *Anacochilus argyræus*, the lanceolate leaves of which are of a deep green, with a silvery band of a similar shape to that of the leaves running from the base to the apex. It received a second-class certificate, as did also *Limatodes alba*, from Messrs. Low, of Clapton. This has pretty pure white flowers in abundance, and comes from Moulmein.

Cypripedium Dayi, exhibited by J. Day, Esq., of Tottenham, received a first-class certificate. Its light green foliage was handsomely variegated with irregular markings of a darker green, and the flowers were also very ornamental.

Messrs. Veitch, of Exeter and Chelsea, had *Barkeria Skinneri superba*, with a profusion of rosy crimson flowers, and on account of its superior merit it gained a first-class certificate; a like distinction being also awarded for *Azalea President Claeys*, which was covered with a profusion of salmon and white flowers. Twelve varieties of *Lycaste Skinneri*, some of which were very beautiful, were exhibited by the same firm, and were considered so interesting as to deserve a special certificate. A variegated *Hibiscus*, from New Caledonia, and having the leaves prettily variegated with white and red, received a commendation. Messrs. Veitch had also *Epacris densa*, with small white flowers, from Western Australia.

From Mr. W. Paul there came a collection of seventy-two varieties of English Hollies, exhibiting many curious and ornamental forms, and which were in illustration of a paper by that gentleman, which was read before the Committee. They received a special certificate.

Of other objects, *Parochetus communis* came from Mr. Pottle, gardener to B. D. Colvin, Esq., Little Bealings; a yellow variegated form of *Araucaria imbricata*, from Mr. Fowler, gardener to the Earl of Stair; *Helleborus olympicus*, came from Mr. Harrington, gardener to Dr. Lindley, Acton Green; and a species of *Begonia*, from South Africa, from the Society's garden, the flowers were orange yellow, and not remarkable for their beauty. Mr. Parker exhibited *Rhododendron Countess of Haddington*, with very large white flowers, delicately tinged with red; and several seedling *Cinerarias* came from Mr. Wiggins, of Isleworth, of which *Formosum*, with very large flowers, white with a broad purplish-crimson edge, appeared well suited for conservatory decoration; *Dark Beauty*, *Princess Alexandra*, and *Beauty of Denmark*, were also pretty varieties.

The large conservatory was extremely gay with Hyacinths, Tulips, *Dielytra*, and other forced flowers, beautifully arranged, and looked even more attractive than the flower show itself.

FRUIT COMMITTEE.—C. W. Strickland, Esq., in the chair. The challenge repeated by Mr. Thomson, of Dalkeith, to Mr. Tillery, of Welbeck, to show old Black Grapes against new Black Hamburgs was expected to come off at this Meeting; but Mr. Tillery wrote to say that on account of the weather, which has been unfavourable to the keeping of old Grapes, his were in such a condition that he did not think it worth-while to send them. Mr. Thomson, however, sent excellent bunches of new Black Hamburgs, which were everything that could be desired both in colour and flavour, and which were considered superior in flavour to the very fine *Barbarossa* exhibited by Mr. Park, gardener to G. Vernon, Esq., of Retford, and those of Mr. Crawshaw, of Cyfarthfa Castle. The *Barbarossa* of Mr. Park were splendid bunches, and the flavour so much superior to what is usually found in *Barbarossa* that the Committee awarded them a certificate of merit; yet they were nevertheless inferior to Mr. Thomson's Black Hamburgs. The *Barbarossa* of Mr. Crawshaw were very fine also; but they were not so rich in flavour as the former. Mr. Tillery sent some good bunches of *Trebbiano* richly flavoured, but thick in the skin, as that variety generally is.

Mr. John Pottle, of Little Bealings, near Woodbridge, Suffolk, sent a handsome fruit of *Prickly Cayenne Pine*, which, however,

was not allowed to be cut, and, therefore, it could not be ascertained whether it was good or good for nothing.

Mr. Park, of East Retford, also sent dishes of d'Auch Pear, Beurré de Rance, and Glon Moreau, all of which were inferior in flavour.

C. W. Strickland, Esq., of Hildenley, exhibited a Yorkshire kitchen Apple of good merits.

Mr. B. E. Cant, of Colchester, sent a dish of Twining Pippin. It is a small, round, dessert Apple, with tender and juicy flesh, sweet, and with somewhat of the flavour of the old Golden Pippin. In good condition for the season.

A seedling culinary Apple was received from Messrs. Wood and Ingram, of Huntingdon, which was remitted to the Secretary to be cooked and reported upon.

Mr. Rivers, of Sawbridgeworth, sent some of the Early Ten-week Potatoes, and Messrs. Ivery & Son, of Dorking, exhibited fruit of an excellent Cucumber, which they called Ivery's Winter Champion, but which was not considered different from some other first-rate sorts already in cultivation.

THE Royal Horticultural Society has done many bold things in its day, but it never did a bolder one than when it essayed a flower show in February; and we should think the experiment is not likely to be repeated, the result being just what one would have anticipated. One was sure that the skill of our horticulturists would be put forth to produce something worth seeing, while the earliness of the date would prevent much from being sent, that the company would be sparse, and that shivering would be the order of the day. Unfortunately, too, for the Society, the Prince of Wales's levee was fixed for the same day; but, fortunately for it, the wind had shifted from its cold quarter, and, under the influence of a south-west wind, warmth was to be obtained by moving briskly about. What it could have been in that cold corridor with a north-easter we were happily only left to conjecture. But even the brilliancy of the Hyacinths and the fragrance of the Lilies of the Valley could not beguile one into the notion that February and a flower show are a well-matched pair. March is even early enough, but three weeks make a serious difference both to flowers and visitors at this season of the year.

One side of the corridor (which formed a part of M. Veillard's unfortunate share of the refreshment department of the Great Exhibition) was filled with plants contributed by Messrs. Veitch, Cutbush, Smith, and Bull, besides a not-very-interesting-looking—though doubtless they were so—collection of Ilex by Mr. W. Paul; the other half by Hyacinths, Crocuses, Primulas, and Tulips, of which the finest collections were sent by Messrs. Cutbush & Son, of Highgate, and Mr. Paul, of Waltham Cross, the contributions sent to the Floral Committee being at one end and a very handsome collection of Hyacinths at the other, forming two groups, sent by Messrs. Cutbush & Paul.

Many of the plants were old and well-known ones, grown with a considerable amount of care, but bearing, many of them, clear evidence of being strongly forced to meet the requirements of the early date named for the Show. In Mr. Bull's collection were some fine plants of novelties, the grand Fern Cibotium princeps being conspicuous for its fine fronds. He had also good plants of Cordyline indivisa and Agave filifera. Why this collection was awarded a second prize I could not quite understand, for it seemed for this time of the year to have merited a first, and there was no other in competition with it.

In Mr. Veitch's collection there were some nicely-bloomed plants, and the same may be said of Mr. Cutbush's; but leaving these to be dealt with by other and abler hands—though I regretted much to observe the absence, from illness, of Mr. D. Beaton, to whose graphic pen we have all been indebted for reports of these shows—I pass on to those flowers about which I profess to know a little. Hyacinths were, considering the early date, most wonderful, and were fine for any season, Mr. Cutbush maintaining the position which he has ably held for many years, though evidently great exertions had been made by Mr. Paul to outstrip him; but there was a refinement and evenness about his flowers very dear to the eyes of a florist, which the others lacked, and which doubtless gained the day for him. Their growth and vigour were something surprising. Of Whites he had Mont Blanc, a fine spike, with large bells closely arranged; Grandeur à Merveille, bluish white, with very large spike; Mirandoline, moderate-sized bells; Snowball, one of the finest of Hyacinths, the bells are beautifully circular and closely arranged.

In Reds there were Von Schiller, a deep salmon pink, large bells, very close, and an immense spike; Princesse Clothilde, delicate pink, striped with carmine; Macaulay, a noble spike, crimson, large bells, and closely arranged. In Blues there were Baron von Tayll, a useful and well-known flower; General Havelock, very dark purple, one of the finest of Hyacinths—the bells are large and closely arranged; Garrick (double), dark blue, with large bells. In Yellows, Ida, a deep-coloured flower and very attractive.

In Mr. Paul's 12 there were, besides some of those already named, Howard, a salmon crimson, with stripes of deeper colour, bells close and spike good; Grand Lilas, a fine and useful azure blue flower; Queen of the Netherlands, a good pure white; Solfaterre, a brilliant orange scarlet, large bells and spike; Charles Dickens, a good greyish-blue with an excellent spike; Lord Wellington, Marie, and Mimosa.

Of the prizes offered by Mr. James Cutbush, about which the Society behaved so oddly, altering the conditions on which they were offered, the first was taken by Mr. A. Carr, gardener to G. W. B. Noakes, Esq., Highgate, with a dozen distinct varieties of good growth, and very similar to those with which Mr. Cutbush obtained his first prize, having amongst them also well-grown plants of La Dame du Lac, a useful rosy pink; and Alba Maxima, a fine white, with large bells closely arranged.

The Tulips exhibited by Mr. Cutbush were excellent. Amongst them were Fabiola, rosy violet and white; Rouge Luisante, fine rose; Keizerkroon, golden yellow and red; Couleur Cardinal, scarlet; Vermilion Brilliant, glowing scarlet; and Proserpine, rich silky rose. In the large collections of Hyacinths, I noticed in Mr. Cutbush's collection, in Whites, fine spikes of Paix de l'Europe, Grandeur à Merveille, Mont Blanc, Miss Burdett Coutts, a splendid flower. In Reds, Solfaterre, very fine; Howard; La Dame du Lac; Reine des Jacinthes, bright crimson, good bells; Madame Hodgson, very fine pale pink; Princess Charlotte, delicate rosy pink, excellent; Mrs. Beecher Stowe, deep rosy pink; Victoria Alexandrina, intense crimson. In Blues, Orondates, an old but very fine flower; Regulus, pale blue; Argus, a bright blue with very distinct white eye; La Nuit, very dark, nearly black; Mimosa, deep purple, very nearly black.

In Mr. Paul's, which were placed equal first, there were some fine trusses. Peineman, an extraordinarily large flower with immense bells, but somewhat loose, of a light greyish-blue colour; Madame Hodgson, Tubiflora, a fine bluish white; Argus, very good, &c.

Several interesting subjects were brought before the Floral Committee. Of Orchids, Cypripedium Dayi, a very beautiful variety of Ladies' Slipper, received a first-class award; as did also Barkeria Skinneri superba, exhibited by Messrs. Veitch and Son. Limatodes rosea alba, exhibited by Messrs. Low & Son, of Clapton, was awarded a first-class certificate. Mr. Bull sent a very beautiful Yucca lineata lutea, with rich golden stripes, to which a first-class certificate was awarded. Trichomanes Pfeuri, a very beautiful Fern from the West Indies, also first-class; and Anectochilus argyæus, which was also given a first-class. Mr. Veitch exhibited a good plant of Azalea President Claeys, of the style of Etoile de Gand; and Duc d'Arenberg, in good bloom, although bearing evident marks of having been strongly pinched to get it into flower. It promises to be a useful and handsome variety.

Several Cinerarias were exhibited. The one that struck me as the best there was Sunbeam, exhibited by the Messrs. Smith, of Dulwich—a very brilliant crimson-edged variety, unlike, so far as I remember, anything we have, moreover well shaped, with the white and scarlet about evenly balanced. They had also a charming little greenhouse plant, Monochaetum sericeum multiflorum, with beautiful crimson mauve flowers, making a lovely object for a basket or pan at this season of the year.

Some branches of the beautiful Bougainvillea speciosa, with its brilliant mauve-coloured bracts, were exhibited by W. C. Thornhill, Esq., Kettering near Northampton, and were as usual the admired of all admirers.

Might one ask whether nothing can be done at these spring shows to give a little warmth to the place where the exhibitions take place? It is possible with great coats, and the ample appliances that the fairer part of creation can make use of to keep oneself from being chilled, though I confess to having gone into the Exhibition building in order to get a good long stretch of a walk. But the poor plants have nothing of the kind, and brought, as many of them are, out of a temperature so high, to one at this season of the year some 40° less, perhaps, I should

think their poor nerves get a shock from which it is very difficult to recover them. They ought, one would think, to be provided with some better place of sojourn than a cold draughty corridor at the sunless side of the gardens.—D., *Deal*.

DO OUR SOILS DECREASE IN FERTILITY?

YOUR correspondent "J." says, in his essay entitled as above, that *Fleta* records in the year 1290, or thereabouts, that six bushels of Wheat were the produce per acre (*vide Fleta*, ii., cap. 8); but he ought also to state on sure authority what was the capacity of a bushel in *Fleta's* time, or is the word properly translated bushel?—N.

[*Fleta* says, that the English penny shall weigh 32 grains of Wheat taken from the middle of the ear; that 20 pennies shall make an ounce; that 12 ounces shall make a pound; that 8 pounds of Wheat shall make a gallon, and 8 gallons shall make a London bushel (*Bussellum*), which is the eighth part of a quarter.—(*Fleta*, lib. ii., c. 12, §. 1). In fact, the above quantities were enacted in 1267 by statute 51 Henry III.]

A FEW DAYS IN IRELAND.

STRAFFAN HOUSE.

ON leaving the princely magnificence of Carton, a beautiful drive brought us to Maynooth, and right opposite the gates of the celebrated College. Years ago we had seen the plans of the building, and had so read of the internal arrangements, and the systems and rules carried out in the instruction and management of such a number of students, that we seemed to look on a place with which we were somewhat familiar, and, therefore, regretted the less our inability to stroll through its more public premises. On the left of the entrance is situated the picturesque church, and on the right the romantic ruins of the castle of the Fitzgeralds, which was built by John, sixth Earl of Kildare, in 1426. The castle was besieged in the time of Henry VIII. by Sir William Brereton, and so great was its strength and the bravery of its defenders, that the besiegers might have besieged in vain, but for the treachery of an adherent within, more influenced by Saxon gold than Celtic honour. Abhorring, as we do, the wildness and extravagance of Lynch law, yet we could not but feel that the betrayer met with a fitting retribution. He had cautiously stipulated for a money recompense, but not for personal safety; and the General, though profiting by the treachery, showed his sense of the wrong by first paying the man the sum agreed upon, and then ordering him to be hung.

The massive keep and ruins are now densely clothed with Ivy, as if for the purpose, as Irishmen will tell you, of concealing the ugly holes made by Cromwell. Almost every nation has its hero and its demon—the man for whom no praise or adulation can be too great, and the man whose memory is looked upon as the incarnation of all that is bad and mischievous. Cromwell, no doubt, is the great demon of the past in Ireland, so far as devastations and ruins are concerned. There seemed to be no clear idea of the definite Cromwell. He might be the Cromwell of the Commonwealth, or the Thomas Cromwell, Earl of Essex, Secretary of State to Henry VIII., and under whose instructions General Brereton, no doubt, acted in the case of the above siege, and who, whatever his faults, stood nobly by Cardinal Wolsey when every other friend forsook him, when he lost favour and influence with the fickle and ungrateful king. Both Cromwells had so much to do with carnage, pillage, and devastation, that we may well excuse the country people making one Cromwell of the two, and hissing out the name as they passed an old battered ruin in terms far from complimentary.

Convinced that we have given more than enough of our attention in the times that are past to something akin to worship of warrior heroes, and paid too much veneration to concentrated energy and mere physical power, it is delightful to find, prompted by whatever cause, great numbers of our brethren turning away from such idolatry, and giving more of the homage of their hearts to the beneficent powers of goodness, intelligence, and useful industry. It was, therefore, with a sense of relief that we passed these ruins and the remains of another castle on the hill of Rathcoffey in such a fine imposing position; crossed the grand canal and the railway for Galway, looked from the hill of Windergates to the rich pastures of Meath in the distance, and now come to the well-cultivated lands of Mr. Barton, which

here join those of the Duke of Leinster, and anon reach the village of Straffan, with its neat cottages, handsome places of worship for Catholics and Protestants, and its flourishing national schools for boys and girls, all speaking of intellectual advancement, social progress, agricultural improvement, and national prosperity—themes far more interesting for discussion and converse, and a thousand times more instructive, than any arousing of the feelings of prejudice and clanship by the keeping alive the memory of the dark and wild deeds of the olden times.

Straffan House, the noble residence of Nathaniel Barton, Esq., and the Hon. Mrs. Barton, is about seventeen miles from Dublin and two miles from the Straffan Station of the Great South-Western Railway. The estate is a very large and compact one, and, with the addition of what is let to over a hundred tenants, Mr. Barton holds 1600 acres in his own hand, under the very able management of his land steward, Mr. Littleboy. This is again divided into four farms, one of which, the home farm, with grass land, wood, kitchen garden, and pleasure grounds, contains about 300 acres, is bounded on one side by the river Liffey, and on the other sides by a high substantial stone wall. We heard Mr. Barton spoken of as fond of flowers, and the Hon. Mrs. Barton as an enthusiastic gardener, who had the pleasure and the privilege of having her ideas comprehended, discussed, and reduced to practical development by Mr. Kelly, one of the best, most indefatigable, industrious, and happiest of gardeners we ever had the pleasure to meet with. Add to this, love of the beautiful, the desire of the proprietors not merely to foster every agricultural improvement, but to elevate the condition of the working people socially and morally by bettering their homesteads and giving abundance of employment; and two things will at once be seen: First, that these proprietors are anxious to act up to the responsibilities of property; and second, that the results obtained demand a fuller and larger inspection, and more ample details than we could possibly give from our short visit.

On passing the village we came to the neat lodge, with a noble arch of Ivy over the gateway, and entered the well-kept approach, 18 feet in width. Passing at first through an old wood, then through an open lawn, with specimen trees and Thorns studded upon it, and fine views of a hill planted in the distance, we reach what seemed massive plantations of evergreens on the left side, but which, on examination, proved to be temporary shelter for groups of the finer and most-prized Conifers; and this, with other planting, conceals the kitchen garden and the stables, until you reach the front lawn of the mansion on the right, backed by masses of timber. Note that from the entrance gate to the entrance hall no obstruction of gate or hurdle was met with, that even the mansion could scarcely be seen until you came right up to it; and thus none of the views from the garden front could be observed unless from that side of the building. Our first entrance was to the stable and coach-yard, close to the mansion, a large square, substantially built with stone, and justly considered one of the best and most convenient in Ireland.

The mansion itself is finely situated on a shelving platform, the ground rising behind the entrance front, and sloping from the garden front to the river Liffey, which is about 400 yards distant. The rich balustrading round the mansion gives it a very elegant finished appearance, and the same may be said of its continuation round the new terraced and panel gardens. From the windows in the garden front and from the upper terraces fine views are obtained of the Wicklow mountains, and near at hand of the hill of Lyons, and the woods and plantations that adorn the residence of Lord Cloncurry. Bringing the eye back for a near view there is spread out before it the series of terraces, sunk panels, and Box gardens, until, passing on to the Liffey and its bright waters, it goes beyond, and rests on a large extent of rich meadow land, on which numbers of sheep were feeding, and cattle up to their knees almost in herbage. Both above and below there are fine picturesque views on the Liffey. Here, to permit of the view, all is comparatively open; but near at hand is a nice island, which has been made the most of by winding walks, a neat cottage in the centre, and a nice suspension bridge for keeping up the communication with it and the main land.

The plan of the main features of these new gardens was given, we understood, by Mr. Howe, and reflect great credit on his judgment and artistic taste. The carrying-out of those plans, and finishing all in the best style, devolved upon our friend Mr. Kelly. Mr. Kelly's own account of it would be sure to be that the Hon. Mrs. Barton did all the work, and he helped her.

Well, it has been well managed between them. It is no uncommon thing to meet with gardeners who are ever harping on the dolorous strains that their merits, their genius, their abilities, have never been yet discovered or appreciated. It was, therefore, very pleasing to find a man of undoubted talents almost

refusing the simplest compliments to his handiwork, the results of no little planning and head-work, and seemingly quite jealous that any such commendation would be apt to interfere with the honour due to the superior intelligence and the more cultivated and refined taste of his much-esteemed employers.

The accompanying cross surface line is supposed to pass from the centre of the fine portico on the garden front along the centre of the steps and the main walk, through terraces and panel gardens, right up to the boundary balustrade, and then over lawn and meadow on to and beyond the river. From the centre of this walk the grounds extend on each side, at the panel gardens, 110 feet, making the space here enclosed 220 feet in width. A will represent the ground floor of the mansion; B, porch across area; C, balustrade, after a wide landing in the porch, part of the staircase of eight steps is formed there, which thus reduces the sloping bank of turf D from the balustrade; E is a level terrace 220 feet long, with a gravel walk of 12 feet in width in the centre, and level grass verges of $7\frac{1}{2}$ feet in width on each side. This walk on the west side is continued, and winds southwards amid mazes of shrubberies, and on the east side, after passing the terrace and small garden close to the site of the conservatory it extends with graceful curves eastwards to the kitchen garden. F is a flight of six steps, with sloping bank on each side; G is a level terrace of grass; H, a grass slope, with twelve steps of Wicklow granite the same width as the walk, 12 feet; I is the line continued up to the balustrade—a length of 87 feet; L is a broken line of 900 feet to the river; and M, the rich pasture on the opposite bank. On each side of the line I, set off 110 feet in another straight line, connect these at the ends and sides with lines at right angles, and you have a parallelogram 87 by 220 feet. Divide that parallelogram from east to west into four, and you have the rough features of these panel gardens, and Box gardens on grass.

The panel on each side of this main walk is sunk a little more than a foot below the level. With the addition of a level verge of turf at the base of the bank H, and the same at the other end next the balustrade, this panel is bounded on the opposite side from the middle walk and at both ends by a gravel walk about 7 feet in width. Beyond this walk on each side the other spaces are devoted to lawn, on which is laid out a Box garden with beautiful artistic tracings; and the spaces are filled with different gravels, as in similar side gardens at Kensington. The panels on each side of the wide middle walk, after these necessary deductions of walks round, levels, and slopes, are 36 feet in width by 57 feet in length, each having a noble granite vase in the centre. The tracings and artistic beauty of these panels are also very interesting, and part of the colouring is obtained from flowers, and part from coloured gravels, not merely between groups and clumps but as groups. There being no walks necessary on the lawn on each side of these panels it is 60 feet in width, and of course 87 feet in length; and on the panels respectively are the beautiful box-coloured gardens already referred to, which, so far as we recollect, appear to all the better advantage from the panels being sunk, and the Box gardens placed on a slope rising to the side balustrade. The design of the plans and the carrying them out give great credit to all concerned. We have, however, that sense of right which would lead us to avoid giving any new plans of gardens to the public without the full sanction and approbation of the artist.

These Box gardens being all of a piece presented to the eye a harmonious unity, as all the colouring of earth and gravels was on one level, whilst the growing Box gave something like life to the whole. So long as ladies are contented day after day to look upon the same appearances in part of a garden, let it be winter or summer, just as they would look down on a fine-patterned carpet on the floor of a room, or the rich artistic papering on its walls, so long will this style of gardening remain popular. In the planting of the panels, we could see nothing with which to find fault; in the surrounding groups with suitable-

coloured gravel, there is just as little to offend the eye; but the filling part of the figures with flowers and other parts as conspicuous with a mere level-colouring of gravel and of earth, seemed to be incongruous, even on the question of unity of outline alone. Suppose we look upon a carpet which is doubly pleasing from the brilliancy of its colouring and the artistic beauty of its tracery, should we, whilst sitting at the parlour fire, consider that carpet was enhanced in beauty by some parts of its colouring being raised about 18 inches, or some other parts depressed as much below the general level, and yet the beauty greatly consist in the whole surface being seen at once? We need not, however, dwell upon this subject, having already treated the matter somewhat largely, and even somewhat incidentally the other week. It is just probable that we may be quite wrong, but at present we are inclined to look on such mixtures as failures, unless where the colour of the flowers and the colour of the gravels as clumps are on a similar level.

In a conservatory in the stove part we noticed a splendid plant of the Brazilian Fern, *Didymochlæna truncatula*, also of *Gleichenia dicarpa*, pubescens, microphylla; large plants of *Gymnogramma Massoni*, *chrysophylla*, *variabilis*, *pulchella*, &c., and fine plants of the better sorts of *Adiantums*, and other Ferns; and under a glass protection a nice collection of *Anectochilus*, with beautiful plants of fine-leaved *Begonias*, and noble plants of the *Hedychium coronarium*, scenting the air with the rich fragrance of their milk-white flowers. In the greenhouse part the column and roofs were richly wreathed with masses of the singular flowers of *Rhodochiton volubile*; and the most conspicuous flowers were fine *Fuchsias*, *Balsams*, *Cockscombs*, &c. Huge masses of *Asplenium marinum* were set on the borders, chiefly for future transplanting; and plenty of *Camellias*, *Azaleas*, &c., were receiving their suitable treatment elsewhere. The flower-beds near the conservatory were very neat and compact. Dahlias were grown in fine style.

Passing along the walk from the terrace already referred to, we soon come to, and pass along the boundary wall of the kitchen garden, the outside of which near the walk is covered with creepers and other plants needing a little protection, as *Jasmines*, *Tea* and climbing *Roses*, *Ceanothus*, *Lonicera*, &c. Between the walk and the wall is a narrow ribbon-border of three rows, ranging thus from the wall—yellow *Calceolaria*, *Tom Thumb Geranium*, and *Variegated Alyssum* next the grass verge. This border from the density of the plants and the abundance of the bloom looked very nice, and was 300 feet in length. We are not quite sure of the position at this distance of time, but we have a vivid recollection of another ribbon-border that looked very nice, and which was thus planted, beginning at the back—Scarlet *Geranium*, yellow *Calceolaria*, Purple *King Verbena*, *Saponaria calabrica*, *Variegated Alyssum*, and *Nemophila insignis* and blue *Lobelia* mixed. Here the *Nemophila* seemed to do as well in the autumn as at Carton.

On entering the garden gate the eye was even more dazzled with beauty than on the new terraces, as two massive parterres presented themselves, one on each side of a central walk, the parterres being backed at the farther end with a range of vinerias and a greenhouse in the middle. We will revert to this garden presently; meanwhile we may state that the kitchen garden seemed large and well cropped, the trees in fine order, the *Apricots* against the wall being, especially, noble specimens. Here, as well as at the terraces, the walks and edgings were in excellent keeping; and a glance at the frames would tell you at once that neither there nor elsewhere would a foot of glass ever be idle at Straffan. The wood of the Vines in the earliest house in the range seemed to be in fine order, and good Grapes were hanging:

in the late house, which might have pleased Mr. Kelly better with a shade of darker colour could he have dispensed with cropping the border in front with flowers, to bring it into character with the parterres referred to, from which it is also separated by a walk of 9 feet in width. It is not the robbery of the border in such circumstances by the flowering plants that does so much damage as the shading of the ground from the sun's rays; and then from a low temperature and frequent dryness the roots are inclined to go too deep; though we do not think Mr. Kelly's good Grapes were showing signs of that. Immediately behind such parterres, and in front of houses, bare earth-borders would hardly be in character; but as these borders are not very wide, a compromise might be effected by making the whole into a sort of terrace walk by covering thinly with gravel. Manure water could be given at any time, other manures in winter; and as then the gardens would not be so attractive, a covering of dung and leaves might be applied to entice the roots to the surface. A line of small baskets or vases would break the monotony, and yet do little to prevent the sun beating on the border, or, what would be the same thing, the gravel or sand on its surface. A slight dressing of fine gravel every spring would make it all look in good order.

One of the most useful helps that Mr. Kelly has, and which he devotes to many purposes, is a house for Melons and Cucumbers, 50 feet in length, 13 feet in width, and 8 feet from floor to ridge. The house is not quite a span, the sash on one side being about 9 feet and on the other side about 6 feet. The door, therefore, of 2 feet 10 inches is not in the centre, but 6½ feet from one side, and 3 feet 10 inches from the other. The path goes down opposite the door, leaving a bed on one side of 5 feet in width, and on the other of 2½ feet; the first intended for Melons, and the second for Cucumbers. These beds or pits on each side of the pathway are rather more than 3 feet from the floor. Under the wide pit are two four-inch pipes for bottom heat and the same for top heat, and under and above the narrow pit the same quantity of two-inch piping. Like many more, Mr. Kelly found it was difficult to give the Melons and Cucumbers in the same division the exact treatment they required in different circumstances, and intended in future to grow them separately back and front in the different compartments.

On our visit about the middle of September were five *Excelsior* Melons in one division, and a fine crop of *Lynch's Star* of the West Cucumber in another, which Cucumber seemed to have a good deal of the breed of the *Syon House*. During winter and spring one or more of these compartments is used for forcing and forwarding what is wanted for use and ornament; and what is not so used is stored with cuttings and bedding plants from floor to ceiling or ridge.

R. FISH.

(To be continued.)

THE MILD WINTER.

THAT the present winter has been exceedingly mild will be generally admitted, but instances like it have occurred before.

The autumn of 1843, if I remember rightly, was very mild, so much so that Mushrooms were reported to be growing in many places up to Christmas, and yet after that we had a winter of more than average severity. The autumn of 1853 was also mild, as I remember gathering some variegated *Geranium* cuttings in the first week of February, that had stood out of doors unprotected and they grew, and yet we had a tolerably sharp frost immediately after that.

The present winter, therefore, is not without a precedent so far. The frosts we had in November destroyed most tender plants, or, at least, it so far injured them that they were removed; but I find a rustic vase in front of my cottage, containing variegated *Geraniums*, has escaped, the plants being yet alive and shooting-out fresh leaves, although in no way protected excepting from the west and north winds. Other *Geraniums* that were left partly with the shelter of shrubs are still green; and *Calceolaria* cuttings put into a cold pit have grown and many of them are knotted for flower, while the old ones in the open border are quite green and as fresh as in September. That they and other plants will receive a check there is every probability, but the sooner the better, as the buds of fruit trees and other plants are advancing too fast; and in the kitchen garden line a mild winter invariably forwards Cabbage plants to the point of running to seed, which would not be the case in a hard one. Peas, too, advance too far to withstand the cold of the late spring, and become what is termed "black in the leg,"

and die. Everything, however, in the greens or Colewort way is in more abundance in mild winters, as, likewise, is Broccoli, Spinach, and other winter crops.

I wonder if the West-Cornwall gardeners, whose doings were so ably reported to us some time ago, are not apprehensive of a late spring frost proving fatal to their Potatoes, since there has been little or none during the winter? However, let us hope for the best, and ere this reach the reader there may be an important change, and our next complaint may be of cold.

My register, as recorded in this Journal for January 6th, shows a greater proportion of west and south-west winds than in former years, and whether this be the cause or effect of the continued mildness is for others to determine. I find, however, that the subject has attracted notice elsewhere. That the present season has been a moist one is admitted, and yet the rainfall of the autumn and up to the present time has not exceeded an average; only falling, as it has, in almost daily dribbles it has kept the roads and every other place dirty. Of the kind of weather in store for us there is no lack of predictions; but, whether after all, any of these prophecies are based on anything better than a mere guess is more than I can tell, and judging from the number of times they are wrong, it would seem that they are nothing more than that.—J. ROBSON.

TRITOMA ROOPERI.

TRITOMAS are allowed by all to be amongst the most showy of all our hardy border plants. *Tritoma uvaria* makes a most telling display, either as single specimens, or in back rows to ribbon and other borders. It is grand throughout August and September. I had a row of this, this autumn, 40 yards in length, with 700 heads of bloom at one time. *T. Rooperi* is also a magnificent plant, coming into bloom in September, and throwing up a succession of spikes all through the winter if the weather be at all mild. Notwithstanding our sharp weather in November, it has been in flower here all winter, and continues in flower at this date (January 16). In October it throws up its flower-stems to the height of 5 and 6 feet, and the individual heads of bloom last in flower twice as long as does any other of the *Tritomas* that I know of. Like *uvaria*, I believe there are inferior varieties of *Rooperi*.

It has been said that these *Tritomas* come true from seed, but I have proved that the best variety of *uvaria* does not; and that from one packet of seed you may get a great many varieties—few, if any, that I have raised being at all equal to the original. A cross between *Rooperi* and *uvaria* would be likely to throw some fine varieties.—D. THOMSON.—(*Scottish Gardener*.)

CRASSULA COCCINEA AND IPOMÆA LEARII NOT BLOOMING.

YOU will oblige me much by advice how I am to manage six plants of *Crassula coccinea*, which did not flower last summer. I have kept them in a cool greenhouse all winter close to the glass, and I have given them very little water. I wish to keep them in pots, and I should like to bloom them this next summer if I can.

I have a plant of *Ipomœa Learii* in a pot, that did not flower last year. Had I better shake it out and repot it in some good soil? I am obliged to grow it in a pot.—L. C.

[Keep your *Crassulas* as they are, and give a little water as soon as you see signs of flagging, or the tops knotting for bloom. You must not think of cutting now, as you will cut all the flower-buds.

Shake out the *Ipomœa*, and give it some rich, rather stiff loam firmly packed. Then cut the head considerably of all the smaller shoots; from every well-ripened bud you may expect a shoot bearing flowers. If you kept the plant in a shady place in summer and autumn, there will be few flowers, if otherwise, in the sun, you will have plenty of bloom on young shoots.]

PLANTING WELLINGTONIA GIGANTEA.—A gentleman whose information is of a very sound and practical nature, respecting the many new and ornamental Conifers, informs me of a case where a *Wellingtonia* has been planted upon an artificial mound made 7 feet high, and which the *Wellingtonia* has now covered with its branches, growing in a sweeping, drooping manner. Seven feet in height thus obtained is a desideratum in many cases when this handsome tree is planted.—W.

PLANT-JUDGING.

THE object of our present remarks is to offer a few observations upon plant-showing generally, and to point out what we consider ought to be the guiding principles in awarding prizes. In judging plants, various things must be taken into consideration—not only the health and general appearance of a specimen, but also the excellence of individual perfections—qualities which appear insignificant when considered separately, but which when viewed collectively, constitute perfection. Thus, supposing a plant had been beautifully grown, was of fine form, had short-jointed wood and clean and healthy foliage, but had flowers in insufficient quantity, ill-formed or badly-coloured, or flowers insufficiently above the foliage, or with unusually long footstalks—these would be great defects, inasmuch as flowers being the aim and end of the cultivator, and the main object of attraction, it is indispensable that they be of the finest and most perfect form and colour. However fine a plant may be, if it is deficient in flower, or the bloom is of bad quality, it is a defect, and in like proportion if a plant is ill-formed or has bad foliage, that also is a defect; but if a plant is unhealthy, that is a decided disqualification, for as prizes are offered to reward skilful cultivation, if

the exhibition shows the want of skill, that is a disqualifying point. A plant to be perfect must be of symmetrical form, be short-jointed, and furnished with robust and healthy foliage from the base upwards. The form should not be formal, neither should the plants bear a rough and uncultivated appearance, but it must be graceful and easy in character, and while it bears the impress of art, must be sufficiently removed from formality to have some of the easy grace of nature about it. The bloom must be large and profusely produced, brilliant in colour, finely formed, and if scented, rich in odour. At the time the plant is shown, sufficient bloom to present a uniform head should be expanded, and it should have a rich, crisp, and glossy appearance. Cleanliness is a great point; consequently every leaf must be free from dirt of any kind, and not an insect must be seen. Plants thus appointed, whether they be hard or soft wooded, come from the tropics or be denizens of a milder climate, will always please; and it matters not whether they be large or small, they all alike show the skill of the gardener—so long as they are sufficiently large to show some mark of cultivation since they left the nurseryman's stores.

Fancy Pelargonium.

Chorozema cordata.

As, however, example is generally better than precept, we here portray two examples of good management—one a *Chorozema cordata* grown in the Royal Botanic Garden, Kew, and the other a *Fancy Pelargonium*, as shown by Mr. Robinson of Pimlico. These may be regarded as perfect specimens of their kinds, are symmetrical in form without being formal, and graceful in outline without being encumbered with numerous sticks. It must, however, be remembered, that a plant may be large and finely formed, and yet not meritorious in point of management, for it may be a plant of very easy cultivation; for instance, the *Chorozema*, though admirable in its way, would not bear comparison with a plant of *C. triangularis*, *angustifolia*, or *Henchmanni*, of the same or even smaller size, while a plant of *Burtonia conferta* or *violacea*, *Boronia serrulata* or *pinnata*, or *Gompholobium splendens*, not half the size, would be infinitely superior and more meritorious. Hence it is necessary that censors should be persons of experience, and practically acquainted with the management of the plants they undertake to adjudicate upon.

Plants also should harmonise in point of size, so that when grouped together they may look as if they came from the same place, and not as if they had fallen together by chance. We once saw a collection of splendid Heaths, averaging from 2 to 4 feet in size, lose the first prize through the gardener putting in a small but admirable plant of *Erica Sprengelii*; and only last year we saw *Cytisus racemosus*, 5 feet high, and *Hoya bella*,

about as many inches, shown in the same group. Such arrangements show bad taste, and ought to be publicly reprobated. It may, perhaps, so happen, that several collections of plants may be so nearly equal in point of merit as to render it difficult to say which is the best. In such a case it is the duty of the censors to examine the plants in each collection separately, both as to form and inflorescence, and then if they were equal, the difficulty of cultivation would decide the point, for if one collection contained plants of more difficult management, that of course must have the first prize.

Size, more especially when it arises from age, is not a leading quality, except in plants of very difficult management, and then the mere fact of keeping them alive and in exhibitable condition is very meritorious, for of course, plants which are very difficult to grow in a young state must require equal skill to keep them healthy when full grown, but plants which have grown large, and have afterwards been twisted and twined about to make them shapely, should not be exhibited at all; for though we cannot join in the cuckoo song which has been raised about growing plants without stakes, knowing it to be impossible, yet it must never be forgotten that they are a necessary nuisance, and never can be used too sparingly or too slight in character. In a few words the leading principles to be observed in plant-judging are—First, that the plants be clean, healthy, and finely formed; second, that they be profusely covered with bloom, the

individual flowers being finely formed, large, and finely coloured; third, that the plants be choice—novelty and tolerable size being always superior to age and large size. Thus, if ten plants were competing, one introduced ten years back and the other only two; and if each required the same skill in management, the new plant, if it had been well cultivated, would be the most meritorious, and should have the first prize. Thus far we have indicated our opinion of some of the rules which ought to be observed by plant-censors, and those who judge individual flowers cannot do better than take "Glenny's Properties" as their guide, for though some of his rules may appear arbitrary, they are in the main correct, and the best that have been published.—(A., in *Gardener's Magazine of Botany*.)

GARRYA ELLIPTICA.

Few plants, even under glass, are more beautiful than this hardy shrub has been the whole of the present winter. Planted against a wall, and only very slightly trained, its beautiful drooping trusses have been elongating since October, and at the present time many of them are upwards of a foot long, the individual florets composing them being fully expanded, and the whole in such abundance as in a great measure to cover the plant, which is at all times a beautiful evergreen. It blossoms and looks well every year, but I have never known it so fine as it is the present season; and to all having a low wall to cover I would by all means recommend this shrub as one of the most suitable; while even as an open standard, or, rather, low bush, it is equally at home.—J. R.

CONSTRUCTION OF CONSERVATORIES.

AMONGST the manifold subjects treated of in your Journal there is one which seems not to have received its meed of attention—"The construction of conservatories."

True, it frequently happens that this important matter is entrusted to some architect whose taste induces him to consider certain conventional architectural forms more than the welfare of plants: consequently an unsatisfactory state of growth follows.

In other cases where the well-being of plants has been considered, external and internal ornament has so swelled the cost that the building of the conservatory has been the cause of checking further improvement.

A few guiding principles as to what really constitutes elegance in glass structures would be of much service to many of the readers of this Journal, and I hope some one well versed in the subject will detail his views.

It would be wrong in me to endeavour to limit these remarks in any way; but one or two simple yet very important questions I should like to see discussed.

First, The relative merits of iron or wooden houses; and if the former are adopted, of what construction?

Secondly, What is the best kind of glass, and what sized sheets are most economical, taking appearance, economy, and efficiency into consideration?

Thirdly, Are domes hurtful or otherwise to plants, and what is the general feeling on their appearance?

Fourthly, What is the best substitute for shading?

Fifthly, Is top ventilation required in a conservatory; and if so, how is it best managed?

Some other useful desirable information may be added to the above, which the nature of the subject will easily point out, and I hope that some of your numerous correspondents will give us their opinion on the matter in all its bearings.—W. H. T.

[We join in this wish, and shall be obliged by the communication of drawings and descriptions of conservatories, whether small or large, that are proved to be handsome and successful as a dwelling for plants. If the cost of construction is added, such communications will be still more useful.—EDS. J. or H.]

PRUNING ROSES IN POTS.

"S., Hampton Court, has three pot Roses from cuttings taken in the early part of last summer, from 1 foot to 1½ high, a Général Jacqueminot, a Mrs. Bosanquet, and a Géant des Batailles. Two are in single stems, and the other has two, both apparently equally strong. Ought he to cut them all down to

the lowest eye, and entirely do away with one of the two shoots? He wishes to keep them as pot Roses, and to have them all next winter in a cool conservatory, so as to bloom earlier in spring than they would otherwise do if kept out all the winter.

[If you wish the plants to bloom this season, merely shorten the shoots about a fifth. If you would sacrifice this and grow them to be finer plants for the spring of 1864, then cut down to 6 inches in length, if you wish to make bushes of them, and if so, it matters not whether you have one stem or several. The one stem would look the handsomest.]

JUDGING GRAPES AND OTHER FRUITS.

As the season for horticultural exhibitions is again approaching, it reminds me of the revival of the discussion of rules for judging fruit, more particularly Grapes, and the desirability of having something like a recognised system, or set of rules for the guidance of the censors.

I have had considerable experience as a judge of horticultural productions at sundry provincial shows, but was never until lately aware that at the great metropolitan exhibitions the practice of testing the flavour of the fruit by the most direct and natural process of tasting was not allowed, or, at least, not practised; but that the flavour was merely assumed from the general appearance.

With all due deference and respect for such authorities as our great metropolitan societies, I will venture to question the consistency of this practice. And the question which immediately suggests itself is this: If the flavour of Grapes can be ascertained without tasting, then why cannot the same rule apply to Melons and other fruit? as with respect to Melons, at least, the practice appears to be always to cut and taste them; and as it must be admitted that Grapes as well as Melons are grown to be eaten. This being admitted to be the case, flavour must always be a paramount consideration (without at the same time ignoring in the least degree appearance, for fruit ought to be "good for food, and pleasant to the eye"), and flavour, I am inclined to think, can hardly be correctly ascertained without a direct appeal to the palate. Another consideration is this: a few berries can be abstracted from a dish of Grapes without necessarily preventing them from being exhibited on a subsequent occasion, or, at least, from being sent to table, whereas the same cannot, of course, be done with a Melon when it has been cut. And, with respect to the latter fruit, it is the constant practice to give the first prize to the best-flavoured fruit, quite irrespective of size or general appearance; and I doubt not many people conversant with the subject, have observed with something like regret, the first prize awarded to a fruit which had nothing but its flavour to recommend it, while larger and more handsome fruit, only slightly inferior with regard to flavour, had a subordinate prize assigned them, or remained unnoticed.

To obviate this, in some measure, a system of points or marks has been recommended, and the suggestion, I think, is worthy of consideration. There is nothing new in the matter, as florists' flowers and plants generally are necessarily judged on something like this principle, and with regard to fruit the system might, I think, be more clearly defined, and rendered more easy of application.

I hope that you or some of your able coadjutors and correspondents may be induced to give the subject consideration, and to bestow on your readers the benefit of the same, and in the meantime, if you will kindly allow me, I will offer a suggestion on the subject.

First. With respect to Grapes, I would confine myself to 11 points or marks, assigning them as follows:—3 points to the best flavoured; 2 to the best coloured; 2 to bloom; 2 to size or weight of bunch; 2 to size or weight of berry.

For Melons I would take 7 points—3 points to flavour; 2 to size or weight; 2 to general appearance.

I have said nothing of degrees of ripeness, as unripe or over-ripe fruit ought to be disqualified.—P. G.

PROTECTING YOUNG TREES FROM RABBITS.

IT HAPPENED to be in Waukegan about the time Rabbits bark young fruit trees, and as I did not know what to do to prevent them, I applied to Mr. Robert Douglas the extensive nurseryman, for a remedy and he told me to mix equal quantities of

lard and soot, and rub the trunks of the trees; but on consultation with a neighbour, who advised lard and sulphur, I concluded to mix all three together; so I mixed equal quantities of lard, sulphur, and soot, and applied it, and it proved effectual. On the trees that were partly barked, it stopped the rabbits from injuring any more, and the trees have completely recovered, and the wounds are healed over. The mixture dried on to the trees, and has protected them since.

The same winter my neighbour had a young orchard of sixty trees completely destroyed, and last winter another of my neighbours had about thirty trees destroyed by them, although he rubbed them with lard and soot; the rabbits eat grease, soot, bark, and all. They ran round in my orchard, and ate all the twigs they could reach, and barked one tree that was not coated with the above mixture; but they never touched a tree that had been rubbed within two years with the lard, sulphur, and soot, because the remains of it were still there.—(*Lower Canada Agriculturist*.)

FEATHERED HELPS IN A GARDEN.

I SEE by a communication from "H.," that he wants "practical enlightenment" on the use of fowls in a garden, and you also state that you will be glad to receive information. I shall be extremely happy to give you my experience, for the subject is mooted at a moment when some vent is required for the emotions which the bare thought of fowls creates in me. The facts are simply these:—I live in a retired neighbourhood, and my particular hobby is gardening. I have a neighbour two doors off whose particular hobby is love of fowls. These two otherwise commendable tastes come into violent collision twice or thrice a-day. The peculiar characteristic of my neighbour's fowls is, that they have an irresistible and unconquerable propensity for coming into my garden in preference to staying in their own. The result is, that I am driven wild every day; and as my wife and family participate in my alarms, the consequences, as you will perceive, are rather serious to well-disposed and peaceable people. I will not delay informing you as to how these lamentable events are caused; and, first, I will speak, as impartially as human nature can do under the circumstances, of the good which fowls do.

The least objectionable of all fowls, excepting small birds, of course, are the hens, and from this category I beg to observe that I rigidly exclude the cocks. Both of them are very fond of slugs, snails, *et hoc genus omne*, and in pursuit of these pests, do a trifling amount of good. The ducks are equally destructive to insects, and are even more persevering in the search of them; but put ducks, cocks, and hens together they will be no more a help to you than a quarter of an hour of personal labour would be.

Now, we come to the opposite side of the balance sheet. My pen fails to paint the agonies which their destructive habits have occasioned me. The cocks and hens knew perfectly well that they were trespassing, and were liable to be prosecuted; but notwithstanding this they would come into my garden several times every day, and the vigour, robustness, and rapidity with which they sent my Sweet Williams, Pinks, Carnations, &c., flying into the air whilst in search of prey, was absolutely sickening to witness. I had a heap of rubbish in an odd corner once, but they have made it "small by degrees, and beautifully less," at the expense of the neatness, order, and cleanliness of my garden walk. This was with scratching.

The ducks do not scratch, but they are still more destructive when they go among softwooded plants. I had a nice bed of Nasturtiums last year, but the ducks had waddled into it four or five times, in search of snails, and the glory soon departed from that feature of the garden. The effect of ducks in a Nasturtium-bed is indescribable. They stagger about like drunken men, and I fancy they like it so well that they must roll in it over and over. Then my Prince of Orange Calceolarias were shipwrecked and knocked to pieces, and the simple fact is this, that I must give up gardening, or my neighbour must give up the fowls. From all this it results that cocks, hens, and ducks do far more harm than good.—R. WELCH, *Bristol*.

HEATING GARDEN STRUCTURES.

I HAVE read with much interest Mr. Robson's papers on ventilating and heating horticultural buildings, and feel assured that many will thank him for giving his experience. I believe it

is a subject that ought to be thoroughly examined, and I would be glad to have the experience of others who have had to deal with particular methods of heating. I, for one, will add what little information I can. I have had nothing to do with Polmaise and several other modes of heating mentioned by the writer, and, therefore, wished, as very likely others in a similar position to myself have done, that he had said a little more relative to them; for although fallen into disuse on account of real or supposed defects, they are not without interest to such as desire to know all that has been done, as well as what may be done, in a matter of so much importance to horticulture.

I once had the management of a small greenhouse, heated by means of a common brick furnace, from which a flue passed under the pathway three-quarters of the length of the house. This was covered with square bricks. The flue then rose above the floor, and was continued back to the furnace, built of brick on edge; here it ascended inside the house, and passed to the chimney. I simply mention this because I think that if the first portion of the flue pass under the floor it may be slower in its effects, but the heat is never lost, and is given-off slowly and in a condition that is never likely to injure the plants; for although I have seen several flues partly carried under the floor I never knew a case of overheating where this was the plan adopted, and, more than this, it allows of two or more laps of flue being placed above the floor. The further from the fire the thinner may be the material of which the flue is constructed, so that pipes may be used with safety.

I am inclined to the opinion that where fire heat is necessary only to keep out frost, as in the greenhouse, there can be no reasonable objection to the flue system. That system has been objected to on account of an escape of smoke happening occasionally; but this must be owing to carelessness in the construction, or, what I have known to be the case, from neglecting to make a suitable provision for clearing-out the soot. When a flue is built bricks should be left out at suitable distances, to be inserted after the other part is finished: these can then be taken out without disturbing the adjoining brickwork. Where this provision is neglected a leaky flue is no uncommon occurrence; for where bricks are well put together it is almost an impossibility to take out one without disturbing several others, and these are generally left so that the smoke can escape through the cracks formed in the process. I have known such instances, and the blame has been thrown on the system; it is more for the want of taking notice of such minutiae than from any defect in the system itself that accidents have happened, even where a permanent heat is required, as in the forcing of Grapes. I have seen some of the very best Grapes that could be grown hanging in a vinery heated on the flue system.

But still there is no reason why hot water should not have its full share of credit; and what I have had to do with hot water has been satisfactory. But then it is one thing to heat 500 superficial feet of glass, and another thing to heat as many thousands. What may be thought economical in the former case may be thought the contrary in the latter. There must be proportions in every case; but this does not alter the fact, that what scientific men are aiming at and have tried to achieve is possible—that is, to give a large amount of heat with a small consumption of fuel. To do this it is necessary that all the heat generated should contribute to the object in view; but how this is to be done is the question. If you burn a pan of charcoal in a room the whole of the heat generated is disseminated throughout the enclosed space, provided there is no outlet for it; but this is not the case in the furnace, which must be provided with a chimney, up which much of the heat ascends with the smoke, escapes at the top, and is lost. This must inevitably be the case to a certain extent; for I do not see how the escape of a portion of the heat in this way is to be prevented, but that is no reason why some of it should not be saved; and sometimes this is effected by having a horizontal flue, in addition to the boiler and hot-water pipes; but unless a good draught can be secured this method does not answer. A boiler fire ought to draw well, or it soon becomes clogged with soot.

One of the best arrangements of the kind I have ever seen, is in the case of a lean-to conservatory I have, until lately, had to do with. In this case the whole of the fireplace and boiler is under the floor. Thus the heat of the fireplace itself ascends through the floor, and acts on the internal atmosphere of the house; it also adjoined a cistern of rain water, and warmed that. The chimney ascended inside the house, a portion of heat was, therefore, secured from that; then there were 120 feet of

four-inch piping, the boiler being of wrought-iron, and the fire heat playing well around it before ascending the chimney. With this arrangement it would be no difficult matter to keep the house of 50 feet by 16, at a temperature of 80°; but to do this it would be necessary to keep a fire going day and night, and this at the smallest consumption of fuel, tells up in the course of a few weeks. The boiler alluded to is a saddle one, of the best of its kind, and set in the most approved manner, and although I believe that the consumption of fuel was moderate, yet the space to be heated was very small compared to what is required of some boilers. There is a vast difference between heating 120 feet of four-inch pipes, and heating 2000 feet of the same-sized pipes, and if a boiler can be constructed on a plan that will heat the quantity of water contained in the 2000 feet of pipes, with the same consumption of fuel that was necessary in the above-mentioned case, a great stride will be made in the right direction.

I believe this is possible, and what I have seen of different kinds of pipe-boilers convinces me that they are most efficient, where a large body of water is to be heated. I do not pretend to say that one kind is better than another; whether Weeks', Ormson's, or Clarke's are most effective. The pipes of these being upright, or nearly so, they are, doubtless, less likely to clog with soot than Messenger's boilers, the tubes of which are arranged horizontally, and are triangular, and fitted so as to leave three quarters of an inch space between. They are made on the principle of presenting a maximum surface of water to the fire; and although this gives a large surface to clog with soot, and, moreover, these boilers require constant cleaning, still I believe they are the most efficient I know of, for heating a large space. But one thing is necessary—there ought to be a good draught, or the many intricate passages the flames have to pass through, damp the fire, causing a waste of fuel. In order to keep the fire going, much has to be raked out that would be otherwise consumed, and however strongly a fire may burn at times, it ought to be so arranged as to be under control, with damper and ash-pit door. Where this is the case, it is not only safer, as when extremely sharp frosts occur, but it is economical in all respects. It would be the reverse of economy to find that the frost had got in, merely because it was found impossible to maintain sufficient heat to keep it out. I firmly believe that hot water is the best, cleanest, and cheapest means of keeping up a permanent heat; but I believe there is still room for great improvement in its application. In fact, there should be no loss of heat from the boiler being placed too far from its work, or other causes, and it should be perfectly under control.—F. CHITTY.

SEEDS FROM BARBADOES.

I HAVE received from Barbadoes some seeds, of which I send a list as nearly as I can distinguish the names. Some are very large. Will you inform me whether they are available in this country? I possess a small stove and conservatory.—VICARIUS.

Abrus precatorius	Bread-and-Butter seed. Botanical
Anona muricata	name unknown
Achras sapota	Canna indica
Circassian berries.	Guilandina Bonduc.
unknown	Lent-blossom tree. Botanical name
Coix lachryma	unknown
Blue Ipomœa	Mimosa viva
Bixa orellana	Sapindus saponaria

[We do not think that you will do much with your importation of seeds from Barbadoes, either for your own growth or in the way of exchange for other plants. In fact, any gardener of experience would be shy of receiving tropical seeds as a gift unless gathered by a scientific practical botanist. To oblige you and some other friends who have had packets of seed sent them, which they value much more than practical men would be likely to do, we will give a few remarks on your list.

ABRUS PRECATORIUS.—This is a strong-growing climber, very abundant in Jamaica, where the roots are used as liquorice, and the seeds as beads. It would require stove heat, and half of a fair-sized roof to grow on, even if the roots were considerably confined. The seeds may be soaked in water at 150° for twenty-four hours before sowing.

ANONA MURICATA is the Sour Sop Custard Apple, which grows as a small tree in most of the West India islands, the fruit being a succulent subacid berry, like a large plum or orange in size, with a flavour and smell like our black currant. It would be worth while to try if this could be made to fruit in a dwarf state.

Sow the seeds in sandy loam in a strong moist heat, keeping the soil rather dry for a week.

ACHRAS SAPOTA, the Sapodilla tree, grows to a good height. The fruit is as large as a quince, with a thick russet skin outside, and a delicious melting flesh inside, with two small stones or seeds in the centre. These sown and raised, the only likely chance for making them fruit in a stove would be by cutting the young seedlings into cuttings, and thus trying to induce a dwarf habit, so as to fit them for our stoves of limited size.

CIRCASSIAN BERRIES.—Never heard of them.

COIX LACHRYMA.—We gave an account of this curious tropical Grass some time ago, and you will manage it very well in your stove. The pearly-like seeds have been called "Job's Tears."

BLUE IPOMœA.—These will require a good moist heat to raise them; and it would be advisable to keep them in rather small pots until you could see a flower. If you sowed them now, and raised several plants, you might try some of them against a south wall after the middle of June. There are so many blue Ipomœas that it is quite impossible to know whether yours are worth keeping until you have proved them.

BIXA ORELLANA.—This is naturally a high-growing tree, and, therefore, we fear you will not be able to manage it in moderate space. There is little attraction about it except its associations. From the pulp which covers the seeds the drug *annatto* is made, which, if not now much used for medical purposes, is, with or without our knowledge, partaken of as a colouring matter in a good deal of the cheese and the butter we use.

BREAD-AND-BUTTER SEEDS.—These we cannot find out by such a name. There are Butter-and-Eggs (the Narcissus incomparabilis), the Butter-bur (the Tussilago), the Butter-nut—a Walnut (*Juglans cinerea*), and there are the Buttercups, which we associate with daisies and the "long-times-ago." Again, there is the Bread-root, the *Psoralea esculenta* of Missouri, where the roots are used somewhat in the manner of potatoes. There is, again, the Bread-fruit, *Artocarpus incisa*, so plentiful and useful in the South Sea Islands, growing there to the size of an oak with us, and with foliage as finely cut, producing fruit as large as a good-sized Swedish turnip; and between the skin and the large core the white edible matter is placed, which is so supplied with starch that when a ripe fruit is roasted it eats very like and is as pleasant as the best wheaten bread. The seeds are generally about the size of a bean. Young plants are to be found in the best London nurseries, and the plants are elegant from their foliage; but we do not recollect seeing the fruit anywhere in this country.

The Bread-nut is the last to which we will refer. This is the *Brosimum alicastrum*, and most likely is what you have, as it grows freely in Jamaica and the West India islands as a slender tree or scrub shrub. It is often met with in our stoves, though there is nothing attractive in its flowers, which, in fact, may be said to have no petals. The mode of fruiting is a good deal like that of *Ricinus* or *Palma Christi*. The young leaves and the young shoots are eaten freely as fodder by cattle; but they are not wholesome as they get hard and full grown. There is a good quantity of milky starch and mucilage in the nut-like seeds which are used, boiled, before they are quite hard; and when ripe and roasted eat very much like a roasted chestnut. In sowing, the nuts may be steeped previously in hot water, or a little piece filed through at the end. If long kept they lose their vitality. If meant for a small stove the seedlings should be made into cuttings to induce a more dwarf compact habit.

CANNA INDICA, the beautiful Indian Shot.—Steep the seeds in water at 140° for twenty-four hours before sowing, and give them a good bottom heat, and keep the surface of the pot covered with damp moss before they appear. If kept in about 50° all the winter they will be good ornaments for the greenhouse in summer. Most seed lists now contain fine varieties of *Canna*. In the south of England they make a fine effect out of doors in summer with their bright flowers and fine foliage.

GUILANDINA BONDUC.—A large tree, chiefly found in the East Indies, producing fine foliage and branches of yellow flowers, and producing its seeds in a bean-like capsule. The seeds would germinate sooner from being steeped in water. We think a house like that at Kew or Chatsworth would be needed for this tree.

LENT-BLOSSOM TREE.—We have no idea what it is.

MIMOSA VIVA.—A pretty, slender, low-growing shrub, rarely rising 2 feet in height, resembling in appearance the Sensitive Plant, which you will find no difficulty in managing in your stove if you give plenty of heat and moisture.

SAPINDUS SAPONARIA is the tall-growing Soapberry tree.—The seed is a nut of a shining black colour, and from its hardness is often used for ornamental purposes. It is covered with pulp about the size of a cherry, and this pulp is used as a soap in many parts of America, though if not used carefully it is apt to destroy linen from its acidity as much as when it is whitened with the help of a little vitriol. Steep the seeds before sowing.

You will now perceive that the most of your seeds either belong to plants that are already common in large botanical collections, or from their luxuriance cannot be managed in small houses with advantage, or, if dwarf, can be obtained from our principal seedsmen. Yours, most likely, will have the advantage of being fresh. You can grow any or all of them as easily in the north as in the south of this country, if you can give them room enough and burn enough coal to give them a tropical climate.—R. FISH.]

ANOTHER MONSTER CALIFORNIA PEAR.

EVERY one doubtless remembers the excitement over the great California Pear produced a few years ago, in the orchard of E. L. Beard, Esq., at San Jose Mission; its weight was over 3 lbs. Rev. Dr. Bellows, President of the Sanitary Commission, has just received notice, *vid* overland mail, that another Pear, from the same tree, weighing an ounce more than the former one, was forwarded to him by the steamer leaving San Francisco Dec. 20, together with other interesting horticultural products.

That Pear has arrived in a tolerably good state of preservation, and is on exhibition at the office of the *American Agriculturist*, at 41, Park Row. The following is the letter to Dr. Bellows, enclosing the express invoice of the Pear.

"Custom House, San Francisco, Dec. 20, 1862.

"Dear Sir,—The other day E. L. Beard, Esq., handed me a mammoth Pear, grown in his orchard at San Jose Mission, California. Having for years been editor of the "Ohio Farmer," this immense Pear greatly interested me—first, on account of its size, and second, because it grew on the same tree that bore the Dr. Bushnell Pear, that created so much interest a few years since in the Eastern States. The Doctor's Pear weighed 3 lbs. and 6 ozs.—this one 3 lbs. and 7 ozs., so that it is the largest Pear ever grown in California.

"When I had sufficiently feasted my eyes on it, I concluded to send it to you, as the man of the east whose affections and gratitude had for the past two months been constantly turned to California.—T. BROWN."—(*American Agriculturist*.)

GARDEN TREES AND SHRUBS AT NEW YORK.

THERE is much more difficulty here to furnish a place with trees or shrubs, suitable for shelter or ornament, than in Great Britain; not altogether from the greater severity of the winter, as this is counteracted in a great measure by the wood, both of deciduous and evergreen plants, being much better ripened in the fall than it is possible for it to be in the British Isles, but rather from the constant alternate freezing and thawing that takes place in February and March injuring the cellular tissue of many plants that otherwise would be a great acquisition, and rendering such a thing as a shrubby unknown, as neither Bays nor Laurels will stand the winter, and Holly even under favourable circumstances merely exists.

It is a strange fact, which I leave for wiser heads than mine to elucidate, that a mild winter is most trying to evergreens, and a severe one to deciduous plants. In proof of this, last winter, which was considered a mild one for this climate, many hedges of American Arbor Vitæ in this vicinity were rendered quite unsightly for some time to come; and an *Abies Douglasii* here, nearly 20 feet high, the finest in this part of the States, was cut down to within a few feet of the ground; whereas clumps of *Hydrangea hortensis*, scattered about the lawn without any protection whatever, stood uninjured, and throughout the summer were loaded with large heads of blue flowers, with here and there a stray pink one to add to the general effect.

Araucaria imbricata lives but does not become ornamental. The same may be said of *Cryptomeria japonica*. *Pinus excelsa* stands well, but its leader seems to be attacked most pertinaciously by some insect, retarding its growth in height, but

throwing it into a very compact bush. Last spring I planted a *Wellingtonia gigantea* here that had stood two winters without protection, and so far it is doing well. The Irish Yew is quite hardy, but the common Yew is liable to be cut down. There are some fine, well-furnished trees here of the old Norway Spruce, which form a most agreeable protection in winter from our biting north-westerly gales, very prevalent at this season. This and the Silver Fir, Hemlock Spruce, and Weymouth Pine form our most generally used trees for shelter. *Taxodium distichum* makes a fine summer ornamental tree, and with its bright green foliage is quite refreshing to look at during the hot weather. *Magnolia conspicua* and *Soulangiana* both about 20 feet high and loaded with flowers from top to bottom in April and May, are a sight worth seeing. *Grandiflora* is generally protected, but stood here last winter without shelter, and flowered well throughout the summer. The Pampas Grass requires protection, but amply repays the care taken of it.

In the nursery of Messrs. Parsons & Co., Flushing, about five miles from here, are some fine specimens of hardy Coniferae, a list of some of which I append. Great attention is paid to this department by the enterprising foreman, Mr. Trompey, who is likewise the most scientific and successful propagator in this part of the States, making fine plants in a short time from grafts, and as he avers without any difficulty.

<i>Abies Menziesii</i>	<i>Picea Nordmanniana</i>	<i>Pinus pyrenaica</i>
<i>Kämpferii</i>	<i>Pinsapo</i>	<i>strobilus compacta</i>
<i>pyramidata</i>	<i>cephalonica</i>	<i>Taxus aurea</i>
<i>Whittmanniana</i>	<i>picta</i>	<i>stricta</i>
<i>Clanbrasilensis stricta</i>	<i>Parsonsiana</i>	<i>Thuja borealis</i>
<i>orientalis</i>	<i>nobilis</i>	<i>Cupressus Lawsoniana</i>
<i>elegans</i>	<i>grandis</i>	<i>Juniperus squamata</i>
<i>monstrosa</i>	<i>pectinata compacta</i>	<i>humilis</i>
<i>Gregoryana</i>	<i>Pinus monticola</i>	<i>hibernica compacta</i>
<i>pumila</i>	<i>Lambertiana</i>	<i>oblonga pendula</i>
<i>inverta</i>	<i>nivea</i>	<i>Cupressus spheroides</i>
<i>compacta</i>	<i>uncinata erecta</i>	<i>compacta</i>
<i>Cephalotaxus Fortunei</i>		

Many of the above are fine specimens, and all are in good health. I may here state, that a Pear from California has been exhibited for the past week, at the office of the "American Agriculturist," New York, weighing no less than 3 lbs. 7 ozs., evidently a monstrous *Duchesse d'Angoulême*, thoroughly looking its weight, and stated to be the largest Pear in the world. A very fine Flemish Beauty, 20 ozs. weight, 12½ inches in circumference, was grown in the garden of an amateur in the village here, last year, and both for form and colour a perfect model.—DAVID FOULIS, *Gardener to Edwin Hoyt, Esq., Astoria, Long Island, New York.*

ENTOMOLOGICAL SOCIETY'S MEETING.

THE anniversary Meeting of the Entomological Society on the 26th of January passed off in a more harmonious manner than was expected, although the Treasurer's accounts showed a smaller balance than in the preceding year, which was attributed to the fact that the Council had carried out their resolution to publish at once all the papers read at the Meetings of the Society, some of which were two years in arrear, and also to the expense necessarily incurred in making-up back volumes of the "Transactions" for sale. These legitimate expenses will not occur again; so that the Society, having still a considerable balance in the funds, may be regarded as being in a flourishing state.

The following gentlemen were elected Members of the Council for the ensuing year:—Messrs. Dunning, Grut, Sir J. B. Hearsey, McLachlan, Pascoe, W. W. Saunders, Shepherd, F. Smith, Stainton, Stevens, Waterhouse, Weir, and Prof. Westwood; and the following officers were appointed:—Mr. F. Smith, President; Mr. S. Stevens, Treasurer; Messrs. Shepherd and Dunning, Secretaries; and Mr. Ianson, Curator.

The President delivered an address to the Society, in which he especially dwelt upon the advisability of rendering the Society's collection of British insects as perfect as possible; a strong opinion has, however, manifestly grown up in the Society as to the impolicy of the Society possessing a collection, which necessitates the expense of a Curator, additional room, and, consequently, increased rent, &c.

Thanks were voted to the President for his speech, which was requested to be printed, and also to the officers and members of the Council for their services during the past year.

THE general Meeting of the Society for February was held on the 2nd instant, with the President in the chair. Donations of

the publications of the Natural History and Entomological Societies of Moscow, Munich, the Netherlands, and Canada, with various other works, were announced. Certificates in favour of Dr. John Leconte, of New York, and Messrs. Lacordaire and Hagen as foreign honorary members of the Society, were read. The President nominated Messrs. Pascoe, Waterhouse, and Grut to be the Vice-Presidents for the ensuing year.

The Secretary exhibited a small box of "manna" collected in Tasmania, being an exudation from the young branches of the White Gum trees caused by the punctures of a species of *Eurymela*, a genus of Hemiptera, allied to our common Cuckoo-spit insect or Frog-hopper, and which infests the trees in the same manner as our Rose Aphides. The exudation rapidly hardens, and dries into a white saccharine mass, and is collected and eaten.

Mr. Frederick Bond exhibited two remarkable moustrosities occurring in *Colias hyale*, the pale-clouded yellow Butterfly, one of the fore wings of which was not more than half the size of the opposite wing; and a female of *Lycana Adonis*, in which the right-hand hind wing on the under side was deficient of many of the ordinary markings, and the fore wing on the same side had only two dots.

Mr. Waterhouse read a communication on *Homalota soror*, and several allied species of minute British Rove Beetles.

Mr. Haward exhibited a collection of Coleoptera collected by himself in central Europe, containing many very fine and rare species.

Mr. Stainton, on behalf of Mr. Healy, exhibited some Bramble leaves, within the burrows of which were visible the cast skins of the larvæ of a species of *Nepticula*. He also read some notes on the peculiarities observable in the moulting of the caterpillars in this group of little Moths, by which it appeared that, although the larva state in the summer time lasted only a few days, in the middle of January it required four days to enable the larva to complete its moult.

Mr. McLachlan read a paper on *Anisocentropus*, a new genus of North American Trichoptera (Caddice Flies), with descriptions of five species; and also on a new species of the genus *Dipseudops* belonging to the same order of insects.

Professor Westwood exhibited drawings of the species of *Lucanidæ*, collected in Gipps' Land at the south-eastern extremity of New South Wales, forwarded by Dr. Howitt.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THE preparation of the various quarters designed for main crops to be persevered in whenever the soil is dry enough to admit of being trodden on without being too much consolidated. This is of great importance on heavy stiff soils, and those who have such to deal with should take advantage of every dry day that occurs. On such soils, too, it will be advisable to defer sowing main crops for a week or even a fortnight. But on light dry soils the sooner the main crops are put in the better, because such soils are most liable to suffer from drought should it occur; and, therefore, the sooner the crops become well established the more likely will they be to resist its effects; if, on the contrary, the season should be a wet one, they will also be in the best possible condition to profit by it. *Beans*, plant out *Mazagans* from boxes and pots. Sow Longpods, regulating the quantity by the demand. *Cabbage*, sow another patch of any early sort, and a few Red for winter use; also, the true Drum-head Savoy. *Cauliflower*, prick out the young seedling plants either on a warm border or a gentle hotbed, to be sheltered in unfavourable weather with hoops and mats. *Celery*, the first sowing to be pricked-out as soon as it can be well handled, and another sowing made of both Red and White. *Leeks*, sow for a principal crop. *Lettuce*, prick-out the young seedling plants, to be treated as advised for Cauliflowers. *Onions*, the principal crops should now be sown. The Deptford, Old Brown Globe, James' Keeping, and White and Brown Spanish are good sorts. Sow them in beds of 4 feet wide, and in drills 9 inches apart, and if you can obtain it, sow some charred refuse along the drills before covering-in. When the beds are raked smoothly over and the surface is a little dry, pass a wooden roller over them several times, as Onions succeed best when the soil is well consolidated. *Parsley* sow a good breadth of the best Curled. *Peas*, on light soils lose no time in getting-in the main crops of summer sorts, together with a few of the later kinds. *Potatoes*, plant both early and late varieties. Those who plant early generally suc-

ceed best. Whole tubers of middling size are preferable to cut sets. Persevere in hoeing, forking, and other surface-stirring amongst all advancing crops.

FLOWER GARDEN.

The digging of flower-borders must now be commenced in good earnest, in performing which use the fork in preference to the spade. All kinds of herbaceous plants may now be planted, either to fill-up empty spaces or to make new plantations in borders which have undergone a course of preparation this season. Pay particular attention to the arrangement of these as regards height, colour, and succession of flowers. Bear in mind that a large profusion of bloom alone does not make a flower-border beautiful and attractive, unless the plants are disposed in such a manner that harmony of colouring may prevail throughout the whole. Proceed with the planting of hardy Roses. Continue the pruning and nailing of climbers; also, the arranging and tying of such as are against trellises, verandahs, &c. Those walks which have become dirty on the surface or are overrun with moss should be turned, which will give a fresh and clean appearance to the surface. Look over autumn-planted beds of Carnations, Pinks, and Pansies, and press down firmly those plants which have been partially raised out of the ground by the late frost. Stir the surface of Tulip and Hyacinth beds where they are aboveground. Look to the sowing of annuals.

FRUIT GARDEN.

Pruning should now be quite finished in every department, and whatever nailing was left undone must be finished immediately. See that newly-planted fruit trees are properly staked and mulched; and after high winds it is necessary to look round them, and to press the earth gently round the base of the stems. All danger of very severe frost being over, Figs may have the coverings completely removed, and be neatly pruned and nailed; do not crowd them with wood.

FORCING-PIT.

Continue to introduce plants of Hydrangeas, Roses in varieties, Pinks, Carnations, Rhododendrons, Kalmias, Heliotropes, and Azaleas. Shake-out a batch of last year's Fuchsias, Erythras, and *Salvia patens*, and place them in bottom heat. Sow Balsams, Cockscombs, Globe Amaranths, &c.

GREENHOUSE AND CONSERVATORY.

Stop any strong-growing shoots of Camellias that are taking the lead when their blooming season is over. Commence syringing freely on every fine morning such Heaths as are freely making their growth, and those that have lately finished blooming. Examine the soil of such plants as the different kinds of *Acacia*, *Genista*, *Cytisus*, *Nerium*, *Eutaxia*, *Myrtles*, the varieties of *Cactus*, and others that may have been resting in the greenhouse for a time, to see if the drainage is all right, and that no plant is suffering for want of water. Many an old corner requires routing-out, and the plants brought forth to receive proper attention.

PITS AND FRAMES.

Those who have not yet attended to the propagation of plants for bedding-out must now begin with all possible speed to put in cuttings of *Verbenas*, *Petunias*, *Fuchsias*, *Heliotropes*, *Lobelias*, &c., so as to have good plants for bedding-out in May. Pay due attention to watering, and topping-back weak and straggling shoots, so as to form robust bushy plants. If any slugs or snails have snug quarters here they will do much mischief if they are not looked after sharply, and destroyed as speedily as possible.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

WE seemed to be rejoicing overmuch over the few days' sun, as again we have had a week of a leaden sky, with scarcely a peep of sunlight to cheer us, though good for carrying on work out of doors requiring muscular energy. Stirred the soil among crops; sowed succession Peas and Beans, in the open air, covering them with burnt refuse to keep off slugs and mice, throwing also a little barley awns along the rows for both purposes, as it pricks the sleek sides of the former, and sticks in the beard of the latter. The greatest trouble at this season is with grass mice, and they are caught with most difficulty, as they will take little except what is green. Some boys are good at catching them with hair and small wire-trap nooses placed in their runs, much in the same way as poachers manage hares and pheasants. They saved us some time ago the trouble of nipping over some Cal-

ceolarias, and they nip over so much more than they eat, that it seems as if they felt a pleasure in the mischief. Ah, well! we would be apt to become careless if we had everything our own way, and had no battles to fight.

Planted out Cucumbers in a small pit which is heated by hot water, as in this sunless weather we cannot obtain heat enough in a frame as yet, as we have little but leaves to depend on for the heat, and must use even them with economy. We gave a section of this pit some time ago, 6 feet wide inside, sunk narrow path at back, and narrow pit in front, two three-inch pipes below, and two in front above, but separated from the bed by a narrow brick wall. The only alteration this year is forming simple ventilators in front, just opposite the lowest of these top-heat pipes, and if a simpler plan can be devised, we should like to hear of it. The ventilator is formed by knocking out a heading brick in the front wall, below the centre of each light, leaving the sides smooth, and having plugs or wooden bricks the size of the opening, but the plugs made in a wedge-shape, so that by merely moving them a little you can admit a little fresh air, which gets heated by coming against the pipes and the inside walls before rising through the general atmosphere. A little of this air from these plugs will be left on almost constantly, except in very severe weather, and thus not only cause the air in the house to circulate but freshen it as well. Some of our friends who advocate Polmaise heating, contend that it is the only plan by which the air in a confined atmosphere can be made to circulate. But that is all a fallacy. In a house heated by whatever means, the air is constantly in motion, even when all the ventilators are shut. We have proved this over and over again, with light down and bits of feathers. No doubt Polmaise, or the drain system connected with it, adds greatly to the force of the circulation. In this pit there are cross drains from the pathway communicating with the space shut in for the top-heat pipes, and when a strong heat is used the draught at these open drains will pretty well extinguish a candle, when all external air is as much as possible kept out.

Removed Kidney Beans bearing from Vine-pit, as it was so crowded we could not move about in it, placed them in another pit in a bed of hot leaves, and planted successions in pots in the same place, preferring pots just now in order to move them easily afterwards. Turned over ground intended for Onions and Parsnips. Planted Shallots and winter Onions. Sowed Radishes and Lettuces where they could have a little protection, and prepared for sowing Parsley. Placed some hand-lights and boxes over Rhubarb out of doors to bring it on a little.

FRUIT GARDEN.

Proceeded with pruning and nailing as opportunity offered; Looked after insects in Peach-house; potted Melon plants, having as yet no place to turn them out in, and stinting when young does them no good; looked over Strawberries on shelves, in every possible position, and if a few seemed likely to do little good removed them at once. This is what few young men will do, they will water and water a pot, whether it is worth the watering or not. In this dull weather water in saucers is very prejudicial; but we said enough on this subject lately. The few plants taken out as not showing well, will be useful in autumn. At present they are turned out of their pots against the north side of a fence, packed closely together, and a little rough leaf mould placed among them, and when we have time we will plant them out, and, most likely, obtain a good gathering from them in September and October.

Some Vines in pots, rather small, have been set inside of other pots of rather larger size, and the latter half filled with rough loam, and have been set in the early vinery, as they will come on before those on the rafters. These, though not extra fine, have shown better than we expected at this early season, as they received no preparation for early forcing, and were merely grown last year in an open, cool, orchard-house. If left to break in that house we have no doubt the shows, which are very fair, would have been better. These are the plants mentioned some time ago as being set in a small frame, with a little bottom heat, and a ridge of horse-droppings all round, to give them a steaming. These, forced with so little preparation, convince us of what some of our readers seem to be in doubt, that fine autumn Grapes may be obtained from an orchard-house, without any artificial heat whatever, whether the Grapes be trained under the roof, or as pillars, or as bushes, or in the raspberry style, provided they have plenty of light. Of course, the brighter the summer and the autumn, the better will the

wood be ripened. If planted out as bushes of different heights, it would be well to have each plant in a pit or box of its own, so that changes could be made without interfering with the general planting. Have just placed some small pots of cut-down plants on the floor of a Peach-house, which we intended to treat in that way; but—

"The best-laid schemes of mice and men,
Gang aft a-glee."

The house in which they were to be grown is at present a vision of the future. In all such hardy vineries, however, a simple mode of heating would be an advantage, as then the Grapes could be kept much longer in good condition, from the damps of autumn being dispelled. Thoroughly washed, cleansed, and limewashed the walls of late vineries, brought the Vines to the front of the house, and then filled it with bedding plants above and below.

ORNAMENTAL DEPARTMENT.

The rough leaf mould laid on the ridged-up flower-beds was not only well sweetened, but the birds and winds were sweeping it over the lawn. Had it swept, the leaves turned-in by a shallow spit, and the lawn well rolled and walked rough-swept, and then rolled when dry. When too close and level at this season, places at all in the shade are apt to become green. There is a great expense in nice gravel walks; but, after all, nothing seems so pleasant for continuous walking exercise. Planted out Anemones, Ranunculuses, Wallflowers, Sweet Williams, &c. Commenced pruning Roses, cutting Laurels, &c. Planted also some edgings of Cerastiums, just dibbling little bits as cuttings about 4 inches apart. If all goes well, they will root in a month or six weeks, and give little trouble. We planted a bed of this and Variegated Alyssum in the autumn of 1861, and found them useful; but this season we were not able to do it. We believe, however, that planting now will answer as well, and with less trouble.

CONSERVATORY.

This averages from 40° to 45° at night now, with a rise from sunshine when we can get it. Gave more water to Camellias, Azaleas, Cinerarias, Primulas, &c. Epacris done flowering should be pruned back and in a few days taken to where there is more heat, taking care not to cut into the old wood. Bulbs and forced shrubs should have a close warm place at first, and if brought from a hotbed in which the pots are plunged, the pots should stand on the surface of the bed, and have more air a few days before moving. Hyacinths and Tulips opening will relish a little artificial manure. The artificial ones sold at the office are very useful for amateurs in small places, as they save much trouble in messing and making up mixtures for themselves. In no case, however, should the quantity exceed the printed directions. It will be safer to give the stimulus a little weaker, and repeat the dose oftener, and to vary the manure at times. Guano must be used for pot plants with great care, as when thoroughly good it is a most powerful stimulant. The superphosphate is one of the safest, either mixed with water or a little dusted on the surface of a pot, to be washed-in by repeated waterings. Shifted the earliest Pelargoniums into their flowering pots, and will use a wet day for training and tying-out a little. Placed the plants in the second vinery, just showing signs of moving, that the Geraniums may be a little closer and warmer than they would be in the greenhouse. Stopped the stronger shoots of those intended for late blooming. Potted-off some to come in late that were struck late in autumn. Potted also some Pink and Scarlet varieties to bloom in pots. Pruned more Fuchsias, and set them in second vinery on the floor. The first lot are now breaking, and when a little more advanced will get rid of a good deal of the old soil and repot in fresh. Potted-off lots of variegated Geraniums, moved a good lot of the first, potted into moveable boxes so as to leave small pots at liberty, as, though the common Scarlets do well put out into beds, to be protected before planting-out time, the variegated ones do best when they have a little ball beforehand.

Proceeded as opportunity offered with taking off cuttings, and hardening-off those already struck, that the fresh ones may go into a hot place. Note here the great difference in striking in spring and autumn. In the latter season all half-hardy plants do best when plenty of time is given to them, and little or no artificial heat used. In the spring, the plants being on the move, will stand, nay, rather delight in an extra stimulus of heat, and, therefore, cuttings of many things may now be made into plants in as many days as weeks would be required in the autumn.

Last season, though it was next to impossible for Calceolarias to do better, we felt the want at planting time of small plants for edgings. To secure them this season, we have just prepared for taking off a good batch of cuttings, which will also make the plants more stubby. For this purpose, beds with hot leaves were prepared much as described the other week for Verbenas. A few inches of rotten dung and leaf mould were thrown over, and a little lime being added to sweeten it, it was trodden firm. Then about 3 inches of compost were thrown over it, and also firmed, and then dusted over with sand. The compost consisted of one part fine sifted leaf mould, one part burned earth and charred rubbish, one part drift sand, and three parts fresh loam, rather adhesive than sandy, put on in a state dry rather than wet. In a few days we will dib the cuttings in, much the same as described for autumn work, only we will keep the glass close and syringe the tops oftener, in the middle of sunny days. The cuttings being from 15 to 18 inches from the glass, will rarely require shading. Among the autumn-struck Calceolarias are some *Aurea floribunda*, rather yellowish and sickly. On examination we found that the cuttings had been planted quite deep enough, and the soil used had been old instead of fresh.—R. F.

TO CORRESPONDENTS.

CERASTIUM TOMENTOSUM CULTURE (*A Constant Subscriber*).—Old plants left in the ground may be dug up, and the soil they have been growing in exchanged for fresh; then the plants, being divided, may be planted somewhat like Box-edging, taking care, however, that sufficient of the couch-like roots be buried to keep the top alive. We find this the easiest way of managing it. Cuttings do as well if taken off beforehand, and struck in heat; but this mode of propagating is more troublesome.

ALYSSUM VARIEGATUM FOR EDGING (*Idem*).—It would not be advisable to have older plants than those struck last autumn. These, with others struck in early spring, are what we use; and we have not found any difference between the two when they are rooted about alike. Old plants might, perhaps, do; but they are bulky to keep through the winter, and are not so handy as young ones.

APPLYING LIQUID MANURE TO A POOR GARDEN (*Aston*).—If your soil be light, liquid manure of any kind may be used almost at any time. Let it be well diluted and clear in dry weather, but on a rainy day you might put it on stronger. Very stiff ground, however, is not benefited by this, but lime will do it good. If liquid manure be inconvenient you might try guano, being sure that it is genuine. A very little of this is sufficient, and it can be used at any time without the disagreeable smell of liquid manure. The inexperienced amateur should be careful to use exceedingly little until he has found out how much should be given.

PRUNING FILBERTS (*H. C.*).—Those not versed in the matter can tell by certain appearances where the female blossoms are, they being small tufts of a bright rose colour. The male blossoms are produced more abundantly, and there is seldom any danger of cutting all of them away. Usually these show themselves early in the autumn, and a succession of them continues up to the time the female blossom is out and gone. Little regard is therefore paid to these at pruning time, but the small tiny buds showing the least bit of red are carefully preserved. They are generally at the base of small shoots, and in Kent are at the present time (Feb. 24), fully open; the trees were all pruned some time ago. This subject will be adverted to again by a writer from the Filbert district, who has promised us notes of his experience.

SOWING PINUS SEEDS (*J. W. W.*).—If your seeds be attached to the cone they are best separated by forcing an iron spike like the prong of a hay-fork up the centre of the cone's stalk, and so dividing them without mutilating them. This is especially advised for the large kinds. Sow in well-drained pans or boxes in a rather sandy soil, covering very slightly, or, in fact, scarcely at all. Some of the larger seeds may be secured to their place by fixing the wing part of the seed in the ground, and the germ only half covered. Some shading from bright sun will be necessary. A cold pit or house will do for them, but some of them germinate more quickly in heat. We do not advise a hot-water soaking which, though it removes the coating of resin or gum, we think injures the embryo. Good seed ought to vegetate without this unnatural process.

SHOOT OF ORANGE TREES DYING (*W. C. H. H. D.*).—It is impossible to judge from the sprig you have sent what is the cause of your trees going off so suddenly. There seemed a little brown scale, but that was nothing particular. Has any poisonous substance found its way to the roots, such as an escape of gas? Has salt water or any poisonous matter been in any water-pots or buckets used in watering them? Orange trees at times become diseased, but they become so gradually; while you say yours were healthy and looked well only a few days ago. There must be something more the matter than we can account for without being on the spot. The roots, we think, from some cause will be found to be defective. Is the drainage sufficient?

SEEDLING CINERARIAS (*Ogston Hall*).—That with dark centre, white-based and mauve-edged rays is a first-class flower. The other is only fit for the garden borders.

STEPHANOTIS FLORIBUNDA (*Stephanotis*).—The Number containing culture of *Lisianthus Russellianus* can be obtained at our office. You have no chance of the *Stephanotis* flowering in the summer of this year if you cut it down now. If you train the four-feet shoot round some sticks, and the shoot has well ripened, you may have a chance of some bloom this year. The best treatment would be to encourage growth without any cutting, and cultivate for flowering in 1864. The *Amaryllis* seeds, sown now, will bloom in two, three, or more years according to the kinds.

FLOWER-GARDEN PLANTING (*H. H. B.*).—We like both your arrangements, but prefer B, but would improve 2 with a margin of pink. We think your centre bed is too large for the rest of the group, but a broad band of *Perilla* will render that excess less apparent. The *Perilla* will require much pruning to keep it below *Bijou*.

FLOWER-POTS BECOMING GREEN (*Kate*).—You may, when they are clean and dry, paint them with whatever colour you admire most. If you used stone-colour paint, and before it was dry daubed it over with silver sand, your pots would look as if made of stone; and thus painted the green will be kept off for a long time. If the paint is well dried before the pots are used no injury will be done to the plants, if the soil is rather open and good drainage secured. If, like Grant Thorburn, you paint the pots green, the green mucus will never be seen even if it come.

POMEGRANATES NOT BLOOMING (*G. F.*).—Your Pomegranate had better stand out of doors after June or in the middle of May. Give it all the sun and air possible; and in pruning manage so as to have abundance of slender twigs, and do not stop or cut them, as they will produce the flowers. If you do not have bloom this season you may have it next. There was an account of the management a few weeks ago.

MILDEW ON GREENHOUSE ROSES (*H. N.*).—The causes are chiefly their being tender and our climate moist. The remedy is giving plenty of air, and dried a little in winter and spring if the roses are started early; and dusting with flowers of sulphur if the mildew does appear notwithstanding that treatment.

PROPAGATING LICOPODIUM DENTICULATUM (*Mary*).—Divide the moss into the smallest pieces with or without roots, and plant in sandy heath mould and a little loam. Keep damp, syringe in sunny weather, and shade a little until well established. You may as well cut over the brown fronds of the Maiden-hair Fern, and give it a warmer position, and fresh fronds will come all right. In your heat the Fern will be brown in winter.

HOYA CARNOSA CULTURE (*Idem*).—It should not be so dry as to wither the leaves. If they are merely a little limp it will be all right enough. A little more heat will also do it good, and before deluging the roots much you may syringe the leaves a number of times in a day, so that they may absorb moisture. In watering make a few holes in the soil, and fill them now and then for several weeks before deluging the soil. Except when in a high temperature in summer and in bloom, this thick-leaved plant needs no great amount of water. The heat should average 45° in winter, and seldom or never be below 40°.

GLAZING FRAMES (*Z. A.*).—If your frames are at all flat, you cannot do better than glaze in the common way, and use quarter of inch laps, and place the glass one way in order that the laps may be as close as possible. If the sashes were to be little moved, the squares finely cut and placed end to end would do, and there would be no drip, but then you would have a good deal of trouble if a square were broken to fit it as nicely again. The same remark applies to fitting-in glass in grooves in the sash-bars, and very little putty is needed; but there is great trouble in mending so as to clean out the groove.

FOREIGN HORTICULTURAL PAPERS (*Gillaume*).—We believe the "Revue Horticole" is the most widely circulating horticultural journal in France. We do not know anything about the Russian journals.

ADDRESS (*Constant Reader*).—Messrs. Carson's address is 9, Great Winchester Street, Old Broad Street, London, E.C.

GERMAN SAUSAGES (*Olivia*).—*Wurst krant* means sausage herbs, such being Sage, Thyme, Marjoram, &c. No particular herb is known by that name so far as we are aware.

CUBA BAST (*P. Q.*).—It is made of the inner bark of *Paritium elatum*, a species hardly separable from the genus *Hibiscus*. It is a native of Jamaica and other tropical islands. The strips of inner bark are there made into cordage. From another species, *P. tilaceum*, native of Otaheite and elsewhere, a fine matting is made of the bark films. The last edition of the "Cottage Gardeners' Dictionary" is dated 1857. It may be had free by post from our office for 5s. 8d.

NAMES OF PLANTS, &c. (*D. D.*).—1, Evergreen Oak; 2, *Escallonia rubra*; 3, Winter Codlin Apple. (*E. F.*).—The Fern appears to be an *Hypolepis*, but is immature. (*Old Subscriber*).—1, *Monochaetum ensiferum*; 2, *Blechnum spicant*; 3, *Taxus adpressus*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHICH SHOULD BE ESSENTIAL POINTS IN POULTRY?

WHILST reading week after week the able writing in your Journal, I have noticed one constant succession of complaints against the awards of prizes at our different shows, and also an endless discussion on the varied points that constitute a really first-class pure bred bird.

I hear individuals speak of a fixed standard; of poultry clubs which are to rule all exhibitions throughout the kingdom, and fix decisions for a never-satisfied crowd of poultry-breeders. Now, the bane of our shows is, that we are not content with the higher and real points that are the marks of prize birds, but we descend to particulars which I think are beneath any common-sense individual to support for a moment.

Why are we to set aside Aylesbury Ducks because their bills have a tinge of yellow? Why withhold the prize when Dorkings have only four toes? Or, why, in that noblest breed of birds, the Game, to bow to the caprice of a judge who may think that they should have different-coloured legs to what they possess?

I take these simply as instances, and I know from experience that numbers of birds of the purest strains in England possess

these so-called failings. Nay, I dare all poultry-breeders of however great standing, to deny that they have not bred as fine poultry in size, shape, and plumage, from their purest fowls, which they have been obliged to set aside on account, it may be, of a bill, or a leg, or a toe, or some hidden feather not being exactly up to the fastidious and overdrawn taste of a judge.

Let us look at another phase of this question. Can we fail to observe the number of fraudulent tricks now played at our shows, which would not exist but for this overstrained taste? Have we never read of the painting of legs, of the addition of toes, or the dyeing of feather, or of countless other methods of cheating which I might mention?

Now, if we really wish our shows to progress—if we wish the encouragement of poultry for their domestic uses—we must lay aside all these gross absurdities, and let each breed stand upon its well-known merits of shape, plumage, weight, or size.

We can never expect that farmers, or labourers, or the poor in general, will ever take up the breeding of poultry as a general trade, unless we break down those barriers, and render the keeping of true-bred fowls more profitable.

I call upon all men who are interested in this branch of industry, who feel these evils (and I know there are many such), now to raise their voices in one united and overwhelming cry for the reformation of such a system.

But, I am far from taking a desponding view of the future; the day is not very far distant when our judging shall no longer be a laughing-stock and a byword to the public in general; but when the breeding of poultry may take its stand among the many well-regulated and profitable trades which now exist.—
A POULTRY BREEDER AND FANCIER.

[Different people will of necessity have different opinions, and different standards of merit in every pursuit: hence it has been necessary to lay down certain rules, and they have been admitted for some years. One great end they answer is to form well-defined marks which may guide the inquirer and the beginner. The use of poultry shows has been to publish the merits and properties of divers breeds; to point out those that are fitted for certain soils and certain markets. Whether the demand be for eggs or for food, the knowledge now acquired and disseminated will enable the purchaser to possess himself of that breed which will answer his purpose. The characteristics of it being pointed out, he cannot easily be deceived.

Thus, he will not buy a Dorking without five claws; but if he is to be told that Dorkings with four are as good as those with five claws, he has nothing to guide or protect him; he is at the mercy of any one who has fowls for sale. There is no substitute for a real Dorking.

Take the Aylesbury Duck. If the buyer is told the bird must have a pale bill, he will not buy one lacking that mark; but if any bill will do, every white Duck to the uninitiated becomes an Aylesbury.

These are but two instances; we might multiply them, but we should not gain by doing so. We ask if there is any good quality given up in order to attain to the standard of excellence as regards points? Have Dorkings lost size? Have they suffered in constitution? Have Ducks dwindled in weight, or have they lost appearance? Spite of all the requirements of the most fastidious judges, you will not find at a good show (take Birmingham for instance), out of the two or three hundred competing pens, a dozen that lack any of the properties insisted upon, while the increase of weight has been *two pounds* per head. The difference in health is proved by the fact, that whereas formerly the class was the dread of managers, and after two days empty pens bearing tickets informing the public the birds were removed on account of disease were one in ten, now such a thing is never seen. Formerly it was thought they could only be reared on the sunny side of a Surrey hill, and that they required a peculiar soil. Now they thrive in Yorkshire, Lancashire, and even in the far north of Scotland.

The average weight of Aylesbury Ducks twenty years ago, was from 3 lbs. to 4 lbs., now it is from 4 lbs. to 6 lbs. Here, again, there has been no sacrifice of any useful quality whatever.

To continue the subject, let us take Pencilled Hamburgs. Roup was thought to be their natural state. People avoided the breed in their yards because they feared taint, and the classes in an exhibition, because suffering birds were not a pleasing sight. There was no inducement to take pains with them, till competition and requirements supplied the spur. Within two years they were shown perfect in colour, shape, and markings, and strong enough to bear any trial in the way of climate or

exhibition. And these were not temporary improvements. Although those who worked the transformation have given up the breed, or gone into other pursuits, it remains the same, and has no more roup than any other.

As a rule, judges are not over-fastidious; but it can never be that hundreds of exhibitors will be satisfied with the decisions of two or three men, or that the knowledge that deals with every class will be admitted cheerfully by those who have concentrated their attention on one. It is doubtful whether there is not more unanimity among judges than exhibitors. Among the latter those points are most insisted upon that are prominent in their own birds, because their owners strive for their own notions of perfection.

If it is granted that after every large show papers contain complaints of the awards, the thing admits of easy explanation. There are often from one to three hundred exhibitors. The majority are unsuccessful. They fancy, or a mischievous friend instils into their minds, that they should have had a prize. Many who would not care to condemn an award openly, will ask why they did not win, or will say they preferred one of the unnoticed pens to either of the prizetakers', under the signature of "INDEX," or "B.," or "Z." Like the man staring at the lion on Northumberland House, to see if he *did* move his tail, the example finds imitators, and a dozen who never thought of it before are moved by a spirit of fun to do the same.

We cannot so easily dispose of the charge of dishonesty and unfairness. We are afraid they are met with in every pursuit, and we fear they always will be. Neither points nor prizes have anything to do with it, and it is as common at chuck-halfpenny as at screaming hazard.

We think the mistake made is in confounding two distinct pursuits—breeding for exhibition, and for sale as food. There is nothing in common between them. The prizetaker sells many fowls. They are all bought either to exhibit or to breed exhibition fowls. Hardly any one who walks round a poultry show look at the birds as articles of food. Calculation, if there be calculation, is about the number of eggs to be sold for sitting, and of the chickens that are brothers and sisters to, or the produce of, the prize birds at the show. They are never bought to improve the quality of market poultry; they are bought for home consumption sometimes.

The farmer will not, the labourer cannot, or is not allowed to keep poultry. The former is above it; the latter has not space. His fowls trespass, or it is thought to be a temptation to him to steal a pocketful of the corn with which he is surrounded when at work, and his master forbids him to keep any.

We see nothing to laugh at in the judgment of those who are acknowledged to be competent, and who are above suspicion. Where the appointment belongs to the person who will perform the office least expensively, it cannot be expected that efficient and superior men will accept it.

The overthrow of shows would diminish the quantity of poultry bred one-half. To relinquish points of excellence is to extinguish poultry shows. There would be nothing to breed and to show for.]

WHITEHAVEN CANARY, POULTRY, AND PIGEON SHOW.

WE shall give our report of this Show next week. The following is the list of awards:—

CANARIES, Yellow Belgian.—First and Second, W. Lyon, Whitehaven. CANARIES, Buff Belgian.—First and Second, W. Lyon, Whitehaven. MULES, Yellow.—First and Second, R. Bell, Whitehaven. MULES, Buff.—First and Second, R. Bell, Whitehaven. PIEDALD CANARIES, Yellow or Buff.—First, R. Bell, Whitehaven. Second, C. Fitzsimmons, Whitehaven. LIZARDS, Gold or Silver-spangled.—First, W. S. Penny, Middlesbrough-Tees. Second, J. Walker, Whitehaven.

POULTRY.

GAME, Black-breasted and other Reds.—First, J. Brough, Carlisle. Second, H. Beldon, Bradford. Highly Commended, C. W. Brierley, Rochdale. Commended, J. Bywell, Whitehaven; J. Gelderd, Kendal. GAME, Duckwings and other Greys and Blues.—First, C. W. Brierley, Rochdale. Second, T. Robinson, Ulverston. Highly Commended, H. Thompson, Milnthorpe.

GAME, any other variety.—First, H. Thompson, Milnthorpe. Second, J. Brough, Carlisle. Highly Commended, J. Doney, Aspatria. SPANISH.—First, W. Cannan, Bradford, Yorkshire. Second, P. Mackay, Millgrove. CHICKENS.—First, W. Cannan. Second, J. Towerson, Whitehaven. Commended, J. Towerson.

DORKING.—First, Mrs. Dixon, Rheda. Second, J. Bywell, Moresby. Highly Commended, J. Doney, Aspatria; J. Todhunter, Whitehaven. CHICKENS.—First, J. Robinson, Garstang. Second, E. Topping, Lane-end. Highly Commended, J. Towerson, Whitehaven; M. Borthwick, Flinby. Commended, J. Doney, Aspatria.

COCHIN-CHINA, any variety.—First, W. Cannan, Bradford. Second, R. Jefferson. Highly Commended, R. H. Nicholas, Newport; F. W. Earle, Prescott; R. Jefferson.

HAMBURGS, Golden-spangled.—First, W. Cannan, Bradford. Second, W. G. R. Jones, Parton. Highly Commended, J. Robinson, Garstang; Commended, W. B. Clarke, Whitehaven.

HAMBURGS, Silver-spangled.—First, J. Robinson, Garstang. Second, W. Cannan, Bradford.

HAMBURGS, any other variety.—First, W. Cannan, Bradford. Second, J. Webster, Whitehaven. *Chickens*, any variety.—First, B. C. Curwen. Second, W. Cannan, Bradford. Highly Commended, W. B. Clarke, Whitehaven; A. Thompson, Cross; R. H. Nicholas, Newport; J. Webster. Commended, J. Hetherington, Lamplough Hall.

POLAND, any variety.—First and Second, H. Beldon, Bradford.

BANTAMS, Game.—First, R. N. Nicholas, Newport. Second, J. Mashiter, Ulverston. Highly Commended, J. Bywell, Moresby; J. Hall, Wigton. Commended, H. A. Clarke, Aspatria; T. Christopherson; J. Cragg, Kendal; C. W. Brierley, Rochdale; J. Mashiter, Ulverston.

BANTAMS, Gold and Silver-laced.—First, W. Cannan, Bradford. Second, J. Bywell, Moresby.

BANTAMS, any other variety.—First, H. Beldon, Bradford. Second, D. A. King, Moresby Cottage. Highly Commended, R. H. Nicholas, Newport; J. Bywell, Moresby.

DUCKS, Aylesbury.—First, B. C. Curwen, Harrington Rectory. Second, H. Beldon, Bradford. Commended, M. Borthwick, Flimby.

DUCKS, Rouen.—First, W. G. R. Jones, Parton. Second, J. Towerson, Whitehaven. Highly Commended, W. Cannan, Bradford; J. Frears, Corkickle.

DUCKS, any other variety.—First, F. W. Earle, Prescott (Black East Indian). Second, W. Cannan, Bradford (Wild Ducks). Highly Commended, J. Cragg, Kendal (Call Ducks); T. Bell, Ulecats Mill (Muscovies). Commended, Mrs. Dixon, Rheda (Mallards); H. Beldon, Bradford (East India); J. Hetherington, Lamplough Hall (Musk Drake); J. Towerson, Whitehaven (Wild Mallard).

PIGEONS.

CARRIERS.—First, J. & W. Towerson, Egremont. Second, R. Pickering, Carlisle. Highly Commended, W. Cannan, Bradford; J. & W. Towerson. Egremont; H. Miers, jun., Whitehaven. Commended, S. Sherwen, Whitehaven.

TUMBLERS, Almond.—First, A. L. Silvester, Birmingham. Second, R. Pickering, Carlisle. Commended, W. Cannan, Bradford.

TUMBLERS, Bald-headed.—First, T. Kew, Westmoreland. Second, H. Miers, jun., Whitehaven.

TUMBLERS, any other variety.—First, H. Yardley, Birmingham. Second, J. & W. Towerson, Egremont. Highly Commended, W. Cannan, Bradford; J. Harrison, Linethwaite. Commended, S. Sherwen, Whitehaven.

POWTERS.—First, H. Yardley, Birmingham. Second, W. Cannan, Bradford. Highly Commended, M. Irwin, Whitehaven; C. W. Brierley, Rochdale; R. Pickering, Carlisle. Commended, T. Kew, Westmoreland.

FANTAILS.—First, A. G. Brooke, St. Bees. Second, R. Brisco, Egremont.

JACOBS.—First, W. Cannan, Bradford. Second, A. L. Silvester, Birmingham. Commended, A. G. Brooke, St. Bees.

TRUMPETERS.—First, J. & W. Towerson, Egremont. Second, W. Cannan. Highly Commended, H. Yardley, Birmingham.

BARBS.—First, A. G. Brooke, St. Bees. Second, M. Irwin, Whitehaven. Highly Commended, A. G. Brooke; M. Irwin; A. L. Silvester, Birmingham.

TURBITS.—First, R. Thompson, Kendal. Second, A. L. Silvester, Birmingham. Highly Commended, R. Brisco, Egremont; R. Thompson; J. & W. Towerson, Egremont.

OWLS.—First and Second, J. & W. Towerson, Egremont. Highly Commended, W. Cannan, Bradford. Commended, S. Sherwen, Whitehaven.

ANY OTHER VARIETY NOT SPECIFIED ABOVE.—First, M. Irwin, Whitehaven. Second, W. Cannan, Bradford. Highly Commended, M. Irwin; H. Yardley, Birmingham. Commended, R. Thompson, Kendal.

RABBITS, Lop-Eared.—First, J. W. Cowill, Egremont. Second, H. Beldon, Bradford.

ANY OTHER VARIETY.—Prize, J. Todhunter, Whitehaven.

GAME COCK.—First and Cup, C. W. Brierley, Rochdale. Second, Mrs. Dodds, Halifax. Third, T. Robinson, Ulverston. Highly Commended, J. Rixter, Whitehaven; J. Mitchell, Egremont; R. T. Choyce, Whitehaven; F. R. Locke, Whitehaven; J. Weeks, Bootle; C. W. Brierley; T. Robinson. Commended, H. Beldon, Bradford; J. Mashiter, Ulverston; J. Brough, Carlisle. *Cockerel*.—First, T. Robinson. Second, J. Blenkinsop, Maryport. Third, H. Beldon. Highly Commended, T. Forsyth, Maryport; I. Wilson, Parton; J. Mashiter. Commended, J. Hall, Wigton; J. Cragg, Kendal; J. Gelderd, Kendal; C. W. Brierley.

SWEETSTAKES, (Turkeys).—E. Weston, Bootle. *Goldfinch*.—W. Lyon, Whitehaven. *Neatest Bird Cage*.—W. Robinson, Whitehaven.

Edward Hewitt, Esq., of Sparkbrook, near Birmingham, officiated as the Judge.

A MEMBER OF THE "LONG FIRM" CAUGHT.

A YOUNG man, named William Ridgeway, was brought up on remand at the City Police Court, Feb. 25th, charged with having stolen a hamper containing provisions and other articles, the property of Mrs. Hampson, Moss Side. At the previous hearing of the case an accomplice, named Lowe, was also charged with the offence; but, as the police had reason to believe that Lowe was merely the victim of his companion, he was yesterday removed from the dock to the witness-box. His evidence, however, supplied no new facts, except that he was acting under instructions from Ridgeway. In the course of the examination it was stated that the hamper containing pigs, for which Lowe inquired at the railway station, arrived soon after Lowe had taken the prosecutrix's hamper. It was addressed "J. W. Ridgeway, Esq., Bentinck Lodge, Manchester." On the follow-

ing day, a man who claimed ten guineas in payment of these pigs arrived in Manchester; but, as he could find no one to give him the money, he returned the pigs to Ireland. In reply to the magistrates, Sergeant Torr, of the detective police, said that the prisoner was a member of the notorious "long firm." He obtained a livelihood by writing to different parts of the country for goods, for which he never paid. He was committed for trial.

BEE-HOUSE.

MUCH has been said from time to time in the columns of your valuable Journal on the merits and demerits of bee-houses; and when I say bee-houses, I mean such buildings, be they of wood or other materials, where the single hive or a whole series of hives is entirely concealed from view. There can be little doubt, I think, that a house such as I speak of, though it prevents the hives suffering from the effects of weather, rain, and so forth, does effectually preclude the admission of that fresh and healthy atmosphere around the hives so conducive to the well-being of the bees themselves. But, again, I think the bee-hive may be too much exposed, and that its inmates may suffer material harm from a want of a proper and suitable protection. If, then, as it appears to me, the protection in the way of an enclosed house is not a thing much to be desired, and if the ordinary earthen covering be not altogether a suitable protection, something, I feel, is required whereby the two evils resulting from too close a protection on the one hand, and from an unsuitable one on the other, may be so rectified as to produce a good result, and this good result may, I think, be brought about by what I would call

THE OPEN BEE-PROTECTOR.

It will be found of simple construction; while it allows of a free current of air passing around the hives, and is so open that the sun's warmth may find its way to each hive, and so tend to the early and more rapid increase of a now large population, it yet effectually keeps off the extreme solar heat, and is also a sufficient protection against wind and storm.

In the model I have forwarded with this communication, it will be seen that the lower frame (fixed) is a barred one, and for this reason, that in the event of the frame being only partially occupied with hives, little or no wet may lodge on the exposed part. The upper frame, also barred, is moveable, and is retained in any required position by two wooden bars running through the main supports of the protector. This moveable frame is furnished with eaves to protect the lower tier of hives from the weather, and being barred, allows of supers being easily worked on the lower hives independently of its own position. The whole is surmounted by a wooden roof, the front a fixture, the back worked on hinges to allow of a more easy access to the upper tier of hives. This, again, has a small coping

roof so constructed as to allow of a free current of air between this and the lower roof, guarding also the upper hives entirely from rain.

Being somewhat a novice in bee-keeping, my ideas as to the suitability of a construction, such as I have attempted to describe as a protection for bees at all times, and in all weathers, may be entirely wrong. However, I am inclined to think that we novices may sometimes make a happy hit, and that more experienced apirians than I at all pretend to be, may not altogether despise the simple protections of "the open bee-protector."—A. K. H., *Westhorpe*.

APIARIAN NOTES FROM MORAYSHIRE.

BEES first seen this season working in the open air on February 10th; on the 13th carrying pollen freely from flowers of early white and yellow-striped crocuses, snowdrops, *Jasminum nudiflorum*, and *Arabis verna*. Vegetation considerably in advance for the season. Weather for the last ten days clear and fine, with slight frosts at night. Observed on the 10th inst. some turnips in full flower in the open field. Furze and daisies flowering commonly. In the gardens Mitchell's Prince Albert rhubarb in the open quarters has stalks 6 inches long.—J. WEBSTER.

BEES IN BUILDINGS.

IN answer to the query of "A NORTH-STAFFORDSHIRE BEE-KEEPER," December 30th, 1862, I have seen the experiment tried different ways, ending in different results—viz., a colony in a garret or attic, south-east aspect, 14 feet from the ground, in the centre of a window 3 feet wide, and about 3 feet from the glass to the centre of the room. It began to breed earlier than usual, and did well, throwing two swarms in that situation. Others I have seen lower down, 1 foot 6 inches to 2 feet 6 inches from the ground, which did very well at a certain season, but in the early spring they did not do so well, for being so low on the ground the damp from the stone wall retarded their operations; and it being close, confined to the side, they never swarmed, for getting into the corner between the hive and the wall, they either lay out inactive, or commenced making combs in the space. With regard to trying them in a building with a north-west aspect, it would not do in this locality, as all the heavy storms come from that direction. They might do very well in good honey weather, but as the honey season generally lasts only about two weeks here, they would probably lose a great many bees in ordinary weather.

Of all the aspects for bees, I have proved to my perfect satisfaction after about fourteen years experience on that point, that a sheltered north aspect is the best, for in winter they are never decoyed out by the tempting rays of the sun, and in summer they work more constantly, and produce more honey, as they are always nearer one temperature. I have always found that a west or south-west or north-west, is the very worst situation for bees, all the other directions being preferable by far to the last-mentioned.

As a proof of what I have stated, I have seen it tried all ways, and as I have a bee-house with the hives facing in all directions, the stocks standing from north to south-east, are always preferable, for the driving storm scarcely ever touches them, and dryness is the great secret in having good thriving hives.—A LANARKSHIRE BEE-KEEPER.

[Thanks for the above. We shall always be glad to hear from you.]

DEATH OF A HIVE'S POPULATION.

A *Disappointed Bee-keeper* sends two pieces of comb from a hive which she has lost within the last three weeks, and begs to be informed what has killed the bees. The hive is one of Neighbour's. The zinc slide over the entrance was partially closed, there being the little space to admit of single bees leaving or entering. One slide at the top was removed and the feeder placed over it, and the cover then placed over the top. The food was not eaten, and evidently not required, as the hive contained a good deal of honey as good as the specimen sent. The hive shows no appearance of damp except those spots where the bees are clustered, a piece of which is sent, and is perfectly free from insects. The bees were all right three weeks since, and were found dead yesterday. The queen was there, and

seems to have died in the same way as the others. Can a fright kill bees? for in a high wind about a fortnight since, the cover which was let down in front of the stand broke loose and flapped a good deal against the hives till secured. Another hive in the same place was also dead, but evidently of dysentery, though they had a good supply of honey in their cells and were perfectly clean.

[Of the two pieces of comb which accompanied the above inquiry, one contained sealed honey of excellent quality, which, of course, perfectly negatives the hypothesis of starvation, whilst the centre of the other is covered with mildew and dead bees. They certainly were not frightened to death; but such a disturbance as is described may indirectly have contributed to the fatal result by causing a number of bees to disperse into the colder parts, of the hive, where they became so benumbed as to be unable to return, whilst the main cluster was so diminished by their defection and chilled by the dampness of the comb, that the whole perished during the next frost. Why moisture should have accumulated on that particular comb whilst all the others remained dry, appeared to us at first an inexplicable mystery; but on showing it to an experienced apirian friend he at once referred it to condensed moisture dropping from the feeder; informing us at the same time of a case in point which had occurred in his own apiary, in which he had found a cluster of dead bees on a mildewed comb under precisely similar circumstances.]

WEST RIDING CONSOLIDATED NATURALISTS' SOCIETY.—The fifth quarterly meeting of the above Society, established for the more rapid dissemination of knowledge in the various branches of local natural science; for making each society acquainted with the natural history of the district of the others; and for the exchange of specimens, &c., was held in the large hall of the Assembly Rooms, Leeds, on the 17th ult., at three o'clock in the afternoon. The meeting was attended by members of the Leeds, Halifax, Huddersfield, Wakefield, and Heckmondwike Societies. After the despatch of the usual routine business, the Chairman requested that any member who had specimens would lay them on the table, when several specimens of Lepidoptera, shells, &c., were produced, among which we noticed three fine specimens of *Antiope*, which were exhibited and verified to have been caught in Wakefield, by Mr. Talbot, of that place, also *P. iota* in the larvæ, pupæ, and imago state, all animate, and bred from the same batch of eggs, by Mr. B. Gibson, of Wakefield. Mr. John Connell, of Leeds, exhibited a series of fossil shells from the Leeds carboniferous formation, and most liberally requested any gentleman present to select specimens for their own cabinets, which generous offer was most freely responded to. The Rev. T. Hicks, B.A., president of the Leeds Naturalists' Society, lectured on "Land and Marine Shells." The lecture was illustrated by coloured diagrams, and the manner in which the lecturer explained the action of the bivalves, the formation of pearls, the provision for renewing the broken shell, and the other interesting phenomena elicited by the topic, gave evidence of a most careful study, extensive research, and a thorough knowledge of the subject.

OUR LETTER BOX.

DEVIZES POULTRY SHOW.—The conduct and management of this Poultry Exhibition is above all praise. I have never had my birds during the eight years I have been an exhibitor returned so expeditiously from any poultry show, and I have never in any instance had the prize money obtained remitted so promptly. Other poultry shows would do well to imitate so good an example. I really hope the Devizes Show will continue to flourish. Such excellent management is well deserving of patronage; and, if the period for holding it were somewhat more judiciously chosen, I have no doubt it would secure the success it so well merits.—P. C., *Oswestry*.

M. SORA'S POULTRY ESTABLISHMENT (*W.*).—We cannot guide you, and the expense of a visit thither we do not think needed, for we believe that we have information on all points connected with poultry which may be fully relied upon; and if you will explain the points on which you want information, we shall be happy to impart it to you. You must make up your mind to begin in a small way, and you must not be discouraged if you fail at first.

FOOD REQUIRED BY POULTRY (*Clumber*).—We can only answer your question with a qualification. The quantity fowls require depends much on their condition. If they have come from a place where they have been fully, if not over, fed, they require but little. They are full of meat and fat, and nature is satisfied and at rest. If they have been on short commons they are ravenous and in a hungry condition. Nature requires food, and for a time at least they are great consumers. Taking them at a medium, we consider a pint and a half of corn should keep a full-grown Dorking during a week, having no other help than that derived from seeking in grass and shrubberies. Half the quantity should be enough in a farmyard where there is threshing going on. Ground food is cheaper than whole food, and oats are better than barley for the purpose. The whole of the corn should be ground, and nothing taken from it.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 50.6° and 33.5° respectively. The greatest heat, 67°, occurred on the 10th, in 1826; 12th, in 1841; and 15th, in 1828; and the lowest cold, 7°, on the 10th, in 1847. During the period 152 days were fine, and on 100 rain fell.

THE RESPECTIVE MERITS OF HOT-WATER AND FLUE HEAT.

THE very courteous letter of Mr. Craw, at page 9, on the above subject, calls for some further remarks; and if in giving my views on this or any other matter, I shall in any way depart from the line of courtesy which graces Mr. Craw's communication, I can only say that rude contradictions, and still less personal offence, are never intended in any article of controversy in which I am engaged. There is the less chance of such intention, inasmuch that, I think it agreeable at times to find a difference of opinion on some of the subjects brought forward; and when the merits of each of the plans recommended are placed before the reading public, a just conclusion may be arrived at as to their respective advantages. John Bull has generally sufficient discernment to know what plan will suit him best, and it consequently receives the support it deserves. The subject now under consideration is one of the utmost importance, not only to the professional gardener, but to the numerous class of amateurs who with limited means are anxious to combine to the utmost economy with efficiency.

A competition between hot-water pipes and flues is likely to enlist a much greater number of advocates on the side of the first-named plan than on that of the other; but this does not dishearten me from advocating the claims of the lesser favourite. It was in certain cases only that I ever meant to urge its claims to distinction, and the general reader will easily comprehend that my purpose was not to urge it as suitable for all places requiring heating, but for those so circumstanced as to fuel and other things, as to make it advisable to adopt the much-despised flue. To make my purpose clear, it will be necessary to allude to collateral matters bearing on the heating of glass structures.

In large places where a number of forcing and other houses are connected together, it is almost needless to say that a well-constructed hot-water apparatus is decidedly the best mode of heating yet known. I give this opinion without any reserve whatever as to the price of fuel or other local circumstances. The respective claims of the various boilers and other fittings I will leave until another time: suffice it here to say, that I cordially agree with Mr. Craw, and others, that for such large and varied structures hot-water pipes stand pre-eminently before flues. But when an amateur puts up a small greenhouse to contain a few plants, or, perhaps, a vinery, which he is not particular about forcing very hard,

No. 102.—VOL. IV., NEW SERIES.

it then becomes an object of consideration to him to adopt the cheapest and most efficient mode of heating that he can consistently with a tolerable certainty that it will work well.

Now, my experience teaches me, that although hot water heats and does its work well on a large scale, it does not do so when the parts are diminutive. Although a large or moderate-sized boiler answers admirably, a small one is often a source of continual trouble and vexation. The reason of this is obvious enough. A fire of fair size will act and do its work well; but a very small one fed by some of those self-feeding contrivances recommended by the inventor, is liable to go out altogether before consuming one-fourth of the fuel, the fuel sticking in the throat of the hopper or feeding channel. This is one reason I have against heating small houses with diminutive hot-water contrivances, and I have seen several disasters from the cause I speak of; while to avoid them, a frequent and confining attention is required, alike inconvenient and punishing to all but the ardent admirer of the contents of the house. This is one of the cases in which I either would advise the old flue, or suggest another description of boiler and heating apparatus than many of such as are now in use.

The next case in which flues have advantages, is in such a place as the one where I noticed they had been worked so long—Ravensworth Castle, where coals are cheap, even more so, I believe, than Mr. Craw has estimated them at. But allowing them to cost 4s. per ton, it follows that it is hardly so necessary to go to a great expense in erecting a heating contrivance to economise coals at that price, as it would be if they were 34s. per ton, and even greater extremes than these sometimes are met with. In my own practice, the highest price I remember ever giving for coals was 40s., and the lowest 1s., or 1s. 6d., and it appears that economy of fuel at the last-named price is not a matter of sufficient importance to be worth spending a large sum in the erection of a peculiar mode of economising fuel. It is, therefore, in places where coals are cheap that I think the merits of the old-fashioned flue are often overlooked; for supposing the saving in coals to be one-half, or even more, it is not an important affair where they are so cheap, and in like manner where the structure requires only to be kept at a low temperature, as for instance, an ordinary greenhouse, where it is only necessary to apply fire to prevent the internal atmosphere falling below 40°, the number of times a fire is really wanted is comparatively few.

Take, for instance, the present winter—an unusual one it must be admitted; but up to the time I write, the 16th of January, we have not had sufficient frost yet to kill out-door Geraniums. Some variegated ones in a rustic vase in front of my cottage, fully exposed, that were injured and lost most of their leaves in November, by some frosts we had then, have evidently not been killed in the stem, as they are now shooting out again. Firing for greenhouse purposes has, therefore, only been necessary to drive out damp; and the frosty nights in which a fire is required to protect the plants, will, most probably,

No. 754.—VOL. XXIX., OLD SERIES.

be few this season. Thus, even where coals are dear, the expense of a hot-water apparatus may be saved in a house of this kind. I grant the case is widely different, when a minimum of 55° is wanted, instead of one of 38° or 40° being maintained. In the former case a continual fire is wanted, and the most economical one is, no doubt, the best, and in such cases hot water stands pre-eminent.

To make the matter of absolute cost appear more plain to those not having had much experience in heating a garden structure, I will give a very common example. Supposing that an amateur wishes to erect a lean-to glass house against a wall that already exists, and at the back of which there is convenience for a fireplace; and assuming the house to be 40 feet long by 15 feet wide, and of a proportionate height at back, the question is how to heat it. Most likely hot water will be recommended. Now, to heat a single house like this, which we suppose to be a plain substantial structure, the hot-water apparatus will cost very little short of one-half the amount which sufficed to erect the building, and, possibly, more than that. This is a large item, and the saving of coals in the heating of one house only is not so much as where there are several all heated from one source; besides, a hot-water apparatus on a large, or moderately large, scale is not half so tedious to manage as a very small one.

Now, this is by no means a solitary case. Many amateurs have the means and wish to erect a house like the one alluded to, with a shelf for plants and other internal fittings, but they feel they have committed an error when, after the house is erected, they find the heating apparatus so costly. To such I would say, Inquire at what expense a flue could be put up, and if that be one-third the cost of the more fashionable mode, it is for you to decide which plan you would like to adopt. The attention and management of both are much alike in regard to trouble—easy enough in both cases, and both liable to go wrong through carelessness.

It would be easy to multiply instances where the flue answers all the purposes of a heating medium; but, be it remembered, I by no means oppose it to hot water in places where many houses are connected, or where they all want warming to something like stove heat. In such cases to use the flue, unless in the coal country, would be imprudent; but this subject as well as that of the comparative cost of a flue with that of hot water, I have gone into more fully in another article, on the "Heating of Horticultural Buildings," so that it is needless inserting it here. I cannot, however, omit repeating that in which I am pleased to find Mr. Crow coincides with me, that the blacks from a smoke-flue are not half so bad as those from the fire of a boiler heated by coal. With regard to the maintenance of a steady heat by flues, a little practice will enable the knight of the stokehole to do that with greater nicety than he ever can with hot water. I speak this from experience, having many times in early life had upwards of twenty flue-fires to manage, and with due attention to the appearances of the weather at ten o'clock at night, so regulated the quantity of fuel put on, that the thermometers in the morning seldom showed more than two or three degrees difference from the point aimed at, and very often that point was exactly maintained; and this without any attention after the hours I have mentioned until six the next morning. Practice alone can insure this, and in the case of a fire put on at bedtime on the sudden appearance of frost setting in, there was, of course, some delay and uncertainty; but generally the night attention required by flues is not greater than that necessary for hot water, and I have never known a flue half so tedious as some hot-water contrivances are.

Of the relative merits of the heat emitted by the new system there is a diversity of opinion, some asserting that that given off by hot-water pipes is more moist and genial to vegetation. That it may be more genial is not unlikely, but in what way it can communicate moisture I am at a loss to know, unless the mode of heating be the open-gutter plan. Certainly, however, the heat is an agreeable one, and unless the pipes be newly painted there is never any unpleasant smell or vapour arising from them. This is, unfortunately, not the case with the flue, for when the fire is first lighted after the flue has been out of use some time there is a very disagreeable odour given off, and now and then there are absolutely escapes of smoke. It is, therefore, best to put on the fire in the daytime and allow the ventilators to be open, and after the flue is dry the smell ceases. When flues are in regular work, there are many who affirm that the heat emitted is less sluggish than that of hot water, the current of air being greater. Whether this be so is more than I can affirm, but it is

certain that in many old-fashioned houses the plants do remarkably well under the old flue system.

I will conclude by again recommending the intending builders of a greenhouse or late graper, to inquire the respective costs of hot water and a flue. If he find the cost of a hot-water contrivance for heating two small houses will exceed what would build a third, and put flues into them all, and if he happened to live in a neighbourhood where fuel is cheap, I leave it for him to decide whether he would rather have three houses than two. This plain way of placing the matter is no vague theory, and is easily understood by any one inquiring what the heating contrivance for single houses costs.

J. ROBSON.

THE ROYAL HORTICULTURAL SOCIETY'S SCHEDULES FOR 1863.

FOR what purpose, we may ask, was the Royal Horticultural Society resuscitated? Did not the late Prince Consort imagine that when he fanned into life that languid spark which had management had pretty well extinguished, it was for the encouragement of floriculture and horticulture? We have now had some little experience of the results, and we may well ask, Was it not for these purposes re-established?

I could say much on many points showing that those objects have not been regarded; but I must confine my notes to my avowed object, and will turn to the schedules.

The times for which the shows are fixed first demand a word. I do not enter into the question of fixing the great shows on the same days as those at the Royal Botanic Society, for this might be laid to the charge of one Society as well as the other. But there were two shows which were eminently successful last year—the Hyacinth Show in March and the Rose Show in July; and what have the Exhibition Committee done this year? They put the Hyacinth Show into February—three weeks too soon; and paid the penalty in having about the tithe of the attendance, and in having several of the most popular flowers wholly unrepresented.

But of all insane things their treatment of the Rose Show is the most mad. Last year they took, I believe, £800, and cleared £400 by it. One would have thought that so good a source of income would have been fostered to the fullest extent: but no! They have killed the goose, and no more golden eggs are to be had—having actually done away with the Rose Show and added it on to their July Exhibition! One knows pretty well what a favourite the Rose is; and how is it possible for persons thoroughly to enjoy it when they have another exhibition to see at the same time? It will be like poor Mrs. Harris trying to see the International Exhibition and the Soane Museum in one day, and coming away with a confused notion that it was very surprising how people could wear such old-fashioned watches now-a-days, and how kind it was of the Queen to send such a large piece of gold as the Victoria trophy when so many thieves were about.

Passing by the spring schedules, only remarking that they seem to be peculiarly shabby, and that there was not much wisdom in requiring Auricula-growers to exhibit six varieties of alpinas and only eight of the ordinary kinds, when, as I believe, there are not more than a dozen kinds of the former and about 150 of the latter, I pass on to the large shows; and one cannot but be at once taken aback at the very large sum given for Orchids—indeed out of the £452 offered in prizes, £113 are offered at the May Show for them, and £124 for stove and greenhouse plants, or more than half for these two classes alone.

I may be told that Orchids are such very expensive plants to grow that it is necessary that large sums be offered for them. Very true, but so are Azaleas. I do not think I am far wrong in saying that a house in which a dozen such Azaleas as are exhibited by the principal growers could be well managed, would grow a collection of Orchids of some five hundred plants; and when the expense of taking them to and from the Show is considered, the balance is all against the Azaleas—not more than three or four plants can be placed in a van capable of containing the whole twenty Orchids.

Again: Is it not time that something be done in restricting the size of greenhouse plants? It is not, as it is with Azaleas, that you obtain a mountain of bloom, for the *Boronia*, *Chorozemas*, *Aphelexes*, &c., which one is now sick and tired of seeing, never make that display; and *Ericas*, hardwooded and difficult plants as they are, are restricted. Why should not

greenhouse plants share the same fate? Next, on what principle is it that amateurs are placed in a more favoured position than nurserymen? "Oh, they sell their plants, and it is an advertisement for them!" But is this to be considered in endeavouring to bring together the best display that can be obtained? I think not; for surely every encouragement should be given to those who so largely maintain the credit of these exhibitions.

Very much was said last season, when the complaints of the florists were brought forward, about the desire of the Council to meet their wishes, and conferences of some members of the Committee with that body were mooted. With what feelings of disgust, then, does one see that, instead of a forward, a retrograde movement has been made! Not only have no fresh flowers been introduced, but Tulips have been excluded from the May Show altogether, while no attempt has been made to introduce Pansies, which are then in their prime.

I object to the term "florists' flowers" altogether, but am compelled to use it for want of a better, although it is indefinite, and might be made to embrace now almost everything that is grown; so that nothing could be more *ad captandum* than the paper that appeared in one of your contemporaries, comparing the sums spent on florists' flowers and on other plants, and showing how largely the florists gained. The truth is, that there is a sort of foolish prejudice in the minds of the Council against cut flowers. Some they cannot do without, but they have tried their best to nullify what they do offer. It is, I believe, the cause of their abolishing the Rose Show as a distinct exhibition. It is also the cause of their peculiarly shabby autumnal show (of which more anon); and to it I suppose we must attribute the exclusion of the Tulip, Pansy, Pink, Carnation, Picotee, and Ranunculus from the great shows.

What folly it seems to be not to endeavour to please all parties. £50 or £100 might very well be spared from stove plants, Orchids, &c., and would satisfy a very large number of real lovers of flowers. As it is, signs of discontent are showing themselves elsewhere. A Chrysanthemum Society has been formed; and one would not be at all surprised to find that this extended itself to other flowers, as was suggested by more than one speaker at the meeting where it was established.

I must ask you to permit me to recur to this subject next week, as my simple desire is to benefit floriculture, while at the same time I do not wish to injure the cause of a Society at whose shows I am—AN EXHIBITOR.

VINES INJURED BY MICE.

I WISH to offer a few words *in re* the mice, as we lawyers say, in answer to an inquiry of your correspondent "R. F.," who weekly favours us with his valuable notes on the "Doings of the Last Week."

He speaks of the ravages of this shrewd little destroyer upon his Vines, and inquires whether anybody else ever knew the like. I never did until this year. I have known rats destroy by wholesale the roots of a fruitful Vine in a garden belonging to my sister at no great distance from this; but I have never known mice do any injury in this respect until the present year.

My Vines, three in number, are planted outside my house, which has apertures for the stems quite sufficient to admit a good supply of air, and, of course, any number of mice. One day my attention was excited by a sort of rustling nibbling noise, which was unusual; but I did not at first give much attention to it. Day after day the same sound struck me, and at last I began to think there must be some cause for it. I accordingly made search, and was not long in discovering the cause; for there sat, as sleek and as fat as high feeding could make him, Mr. Mouse, just under the front shelf of the greenhouse, and in close contiguity to one of my Vine stems. I could not deal with the offender at the moment, but it led me to make an investigation, the result of which was that I discovered that all my three Vines were gnawed quite to the inner bark by this pestilent little enemy. I immediately went to work, and set four or five traps with the most tempting baits I could think of—peas, beans, and new cheese—but all in vain; he preferred the sweet juices of the Vine to all my dainties; and at last I was obliged to cast humanity to the winds, and transfix him with a fork, and so I delivered myself from my enemy, and I hope saved my Vines. Had he been allowed to continue his ravages a little longer I fully believe it would have been all over with them, and I do not yet feel certain they are safe.

I should mention that it was not on the Vine stems only that he had feasted, for he had treated in the same way a good many bedding Geraniums which stood on the shelf in front of the house; these he had barked all round, and of course they were completely destroyed. I subsequently caught a second, not by the same cruel process, but in one of my traps, which confirms me in the view I have been led to take, that at this season of the year mice go in pairs, and, therefore, if you mean to exterminate your enemy you must deal a double blow.

A word or two now as to the cause of this unexampled inflection. Generally in this quarter of my garden I have early Peas and Beans. This year I have none, and my garden has been particularly bare of everything that would seem to be the legitimate food for this destroyer.

As the thief says when taken, "We must live somehow," and so, as there was nothing for them outside the house, my little friends thought it no trespass to venture inside in search of a livelihood, and have paid the penalty.—R. R.

A FEW DAYS IN IRELAND.

STRAFFAN HOUSE.

(Concluded from page 169.)

We must now finish by giving some account of this very striking flower garden, consisting of two massive parterres which present themselves on entering the gate, one parterre being placed on the left hand, and the other on the right hand of the main gravel walk which divides them from each other; the parterre on the one side is a counterpart of that on the other side. The main walk is 9 feet in width. A plan of one side is here given. The beds are all nicely Box-edged, and divided from each other by gravel paths of 3 feet in width. These parterres, each 120 feet by 56 feet, were laid out by Mr. Kelly; and the Hon. Mrs. Barton and Hugh Lyndoch Barton, Esq., take great interest in the arrangement and planting every season.

One of the charms of this garden for flowers placed in a kitchen garden is, that just like a similar garden at Raith, which we noticed some years ago, when looking at the flowers no views or considerations of the merely useful are obtruded upon you, unless, perhaps, a bright vision of luscious Grapes in the vinerias at the farther end already alluded to. Everything connected with the kitchen garden is excluded from sight or thought by a fine Privet hedge on each side, 10 feet in height, though planted only a few years. In front of this hedge, longitudinally, are a series of bold wide arches covered with hardy creepers, with fine Hollyhocks in the openings; and in front of these again, each in its separate bed and at equal distances from each other, a fine row of healthy large-headed tree Roses of equal height and of the best kinds. Standing on the central walk, on whichever side you look you are presented with a fine rich background to reflect the brilliant colours in the beds. We must content ourselves with a few words on the position of the parterres, the styles of planting, and a hint or two to be considered if not adopted.

The first impression as the eye goes from side to side of this garden is one of overpowering brilliancy, from the vast blaze of colours presented in one uniform slope or level. This very brilliancy, the great number of beds, and their nearness to each other, are apt, when looked at from a distance, to mingle and merge together, so as to give variety of shade instead of distinctness in colouring. This would be still more the case but for the incline of the ground.

Such parterres, to be seen to the very best effect, should have such a position as they would have enjoyed, had they been one on each side of the fine flight of steps that takes you to the panel gardens. The next best would be the position they now occupy, but with that centre walk some 2 feet higher than a regular ground level of the flower-beds. The third best is that which has been adopted, not a ground level the same as that of the walk, but rising from it by a gentle incline on each side. By this means the plants in the farthest beds are brought nearer the eye, and are seen more distinctly than if all the beds had been on the same level. This effect was also frequently increased by the taller-growing plants being used next the line of Roses, and the dwarfier ones next the middle main walk; but always so as to preserve uniformity of slope, showing the advantage in such an arrangement of studying heights as well as colours.

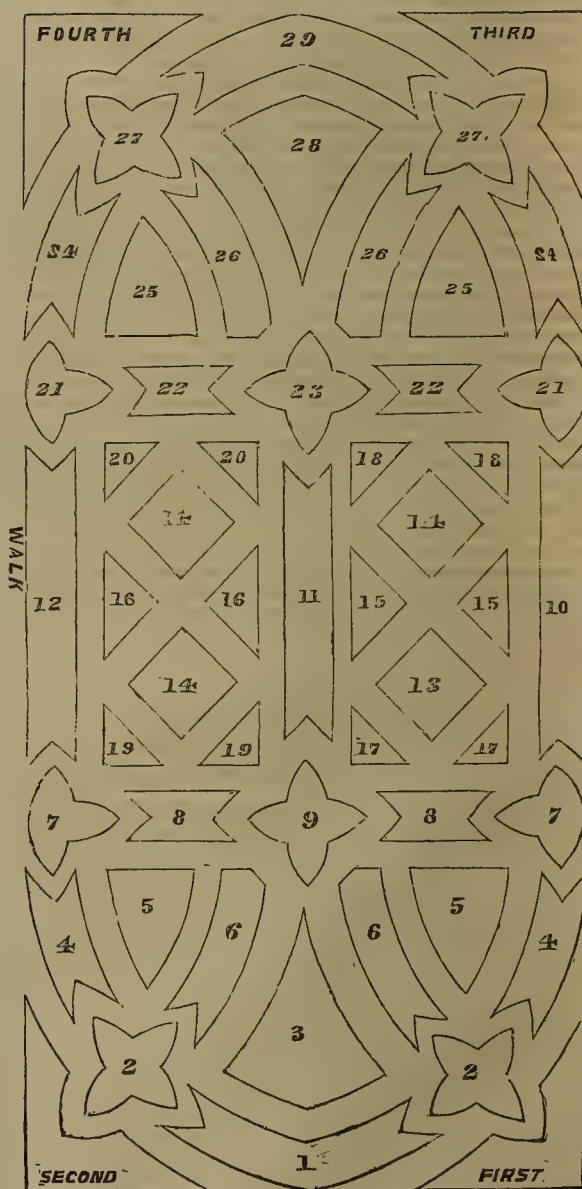

"Uniformity of slope! Why that is next thing to uniformity of level, or keeping clumps on the level!" we think we hear a learned gentleman say, who wrote us such a nice letter last week,

that we hope he will give the purport of it somewhat enlarged to the Editors for the general benefit; the purport of the part of the letter to which we are now referring being an advocacy for planting beds on the level instead of elevating them at all in the centre—in other words, objecting to the opinion we expressed of the raised beds on the terrace of circles at Woodstock. Now, with all due deference to the opinion of our kind Mentor, we should not easily be convinced that that terrace would have anything like the same gorgeous effect, if each circle were planted so as to be level across; but we thoroughly agree with him, though we should not object to a few prominent raised parts, that in such a parterre as is here represented, if placed not only beneath the eye but below the level of the feet of the spectator, the more level each bed is from side to side, and the more uniform the general level of the beds throughout, the better will be the effect. To raise the beds of such a parterre much in their centres would throw the whole into a series of ridge and furrow; and, therefore, when looked at from a distance, little except the ridges of the farther beds could be clearly seen. The same principle must be kept in view in the slightly sloping ground of these parterres. The beds as a whole should not only be level, and plants of similar height be used as much as possible so as to lessen pruning and pegging, but the rising slope of the ground may even be added to, by having the tallest plants next the Roses. Any great break in the uniform slope would act as a ridge and conceal what was beyond. Circumstances, therefore, should regulate treatment and modes of action. We see no reason why a single bed, a terrace of a line of circles, or even an avenue of beds, whatever their form, should be treated the same as a close-packed parterre, over which the eye is intended to sweep at once.

The beds of these parterres were not only well filled, but there had, on the whole, been an extremely successful attempt made to secure the desirable level and slope. If you ask us what was the system of planting as respects colours adopted, we should be inclined to say, it was a system thoroughly orthodox, and yet perfectly heterodox. Even a passing examination would have given you examples of shading, examples of contrast, instances of balancing, and instances of uniformity; but then these appeared to come in less as a matter of primary design than as adjuncts to carry out the main idea, which seemed to be that each parterre should in itself form a harmonious whole constituted of as diversified parts as possible. It was, therefore, but seldom that the opposite pair or balancing-beds were planted alike, or even of similar colours. We never could please ourselves with this mode of planting, and we never were thoroughly satisfied with what has been done by others. As carried out at Straffan, it was by far the best we had seen, and that most likely because the idea was not driven too hard. There must have been ten times more thought required than any mere simple system of centering and balancing, and to us the latter with all its simplicity is the most pleasing. We have had many rubs on this subject already; and, as in the case of the raised circles, we expect to get many more from the ladies and gentlemen of progress. Well, after a fair share of bantering, we have gone to some places to see the working-out of this grand new idea where variety is to be everything, and balancing and uniformity nothing. We have seen single beds with six or seven patches of colour and of all heights and sizes, and frequently the highest where the lowest should be. We have been asked to admire the beauty of a geometrical group where not only no two beds were at all alike in colouring, nor yet any bed that had its own ends and sides balanced either in colour or in height. And then there were ribbon-beds and borders looking one way, with tall plants at the back, and low plants between tall plants, and all for variety. And, again, there were ribbon-borders that faced two sides, with one side filled with tall plants as if they meant to go to the clouds, and the other side not only dissimilar in colour, but clothed with plants so clinging to the earth as if they wished to gravitate to its centre; and all this striving for variety and much scheming for effect ending in what most people, except the planners, looked upon as a careless, unmeaning pitching of things together. One of the most earnest of these mere variety advocates, pointed somewhat triumphantly to a pretty pair of ponies in a phaeton carriage, one cream-coloured, the other a piebald, like a magpie, and exclaimed, "You see I will have variety in everything." "Not quite yet," was the calm reply; "the two sides of the carriage are yellow, the two wheels are blue. What a pity there should be any uniformity."

Could we see the desirableness of encouraging this mere taste

for variety instead of any attempt at balancing in regular geometric parterres, we should have given the planting in these parterres at Straffan in 1861 as combining variety and some little duplicating and balancing with much harmony and beauty. But as Mr. Kelly has most kindly given us the lists of several years' planting, and told us to take which we liked, and say and do just what we liked with them, we have with some reluctance taken the planting of 1862, because assured by visitors that the results were at least equally gorgeous with 1861, because we ourselves are more pleased with the more simple mode adopted, and because Mr. Kelly himself, after being so successful in planting for variety, has last season adopted chiefly the balancing system.

The beds are all numbered, except the four large ones at the four corners, which are named first, second, &c. The parterre on the left-hand side of the centre walk was thus planted:—1, *Lobelia speciosa*; 2, 2, *Yellow Calceolarias*; 3, *Tom Thumb Geranium*; 4, 4, *Lord of the Isles pink Verbena* and *Saponaria calabrica*; 5, 5, + cross of *Tom Thumb*, filled up with *Flower of the Day* and *Manglesii Geraniums*; 6, 6, *Purple King Verbena*; 7, 7, *Annie Clayton Verbena*, white, and *Cerastium tomentosum*; 8, 8, *Mrs. Archer Olive Verbena*, maroon, and *Rouge et Noir Verbena*; 9, *Yellow Calceolaria*; 10, ribboned—

centre Golden Chain Geranium, sides *Lobelia speciosa*; 11, Perilla centre, *Tropæolum Stamfordianum* sides; 12, ribboned—*Heliotrope* centre, sides Tom Thumb Geranium; 13, 13, *Cerise Unique* Geranium, and Lord Raglan Verbena; 14, 14, Silver-edged and *Manglesii* Geranium; 15, 15, *Gazania*, and Mrs. Moore Verbena; 16, 16, *Victory Verbena* and *Tropæolum elegans*; 17, 17, *Mesembryanthemum tricolor* and *Lobelia*; 18, 18, *Lobelia* and *Mesembryanthemum*; 19, 19, *Mesembryanthemum* and lilac Verbena; 20, 20, lilac Verbena and *Mesembryanthemum*; 21, 21, white Ivy-leaved Geranium and *Cerastium*; 22, 22, *Rouge et Noir* and *Hendersoni* Verbena; 23, yellow *Calceolaria*; 24, 24, pink Geranium and Mrs. Mildmay pink Verbena; 25, 25, cross + Tom Thumb, filled with Flower of the Day and *Manglesii* Geranium; 26, 26, Purple King Verbena; 27, 27, yellow *Calceolaria*; 28, Thompson's King Geranium, scarlet, with dark horseshoe leaf; 29, *Lobelia speciosa*. Angle beds:—First, centre row of *Hendersoni* white Geranium; row on each side of Thompson's King, scarlet; and two rows on each side of *Manglesii*. Second bed, centre Oakleaf Geranium; then two lines of scarlet *Duchess of Leinster*, and two lines at side of cinnamon-scented Geranium. Third bed, *Shrubland Pet* centre; Silver-edged Geranium, two lines; pink Ivy-leaved, two rows all round. Fourth bed, *Cooperi*, scarlet Geranium for centre, fine; two rows of *Hendersoni* on each side; and two rows round the sides of *Cerise Unique* Geranium.

On the right-hand side, the same figures and numbers being next the walk:—No. 1 is Miss Trotter Verbena; 2, 2, yellow *Calceolaria*; 3, *Madeline*; 4, 4, Purple King; 5, 5, + pink cross, filled with white *Saponaria* and *Cerastium*; 6, 6, *Duchess of Leinster* and *Commander-in-Chief* Geranium; 7, 7, Miss Trotter and *Defiance* Verbena; 8, 8, Purple King Verbena; 9, yellow *Calceolaria*; 10, Flower of the Day centre, filled with *Hendersoni* Verbena; 11, centre Scarlet Geranium, filled with *Lobelia speciosa*; 12, *Manglesii* Geranium and *Venosa* Verbena; 13, 13, Mrs. Mildmay Verbena and Lord of the Isles; 14, 14, Annie Clayton and Bridesmaid; 15, 15, *Gazania* and dwarf Purple *Nosegay* Geranium; 16, 16, *Géant des Batailles* Verbena and *Crimson Nosegay* Geranium; 17, 17, cinnamon-scented Geranium and *Mesembryanthemum*; 18, 18, *Monoth* Verbena and *Harkaway* Geranium; 19, 19, *Evening Star* Verbena and *Mesembryanthemum*; 20, 20, *Mesembryanthemum* and cinnamon-scented Geranium; 21, 21, *Evening Star* and Lord of the Isles Verbena; 22, 22, Purple King Verbena and *Lobelia*; 23, yellow *Calceolaria*; 24, 24, Emma and Hector Verbena; 25, 25, pink cross + Verbena, filled with Annie Clayton, surrounded with *Cerastium*; 26, 26, Tom Thumb and *Duchess of Leinster* scarlet Geranium; 27, 27, *Amethystina* Verbena; 28, yellow *Calceolaria*; 29, Lord Raglan Verbena. First angle bed, scarlet, centre row of Tom Thumb; two rows on each side of *Manglesii*; and two rows of *Lobelia speciosa*. Second bed, *Perilla*; centre row, *Tropæolum elegans* two lines, and two rows of *Variegated Alyssum*. Third bed, variegated crimson Ivy-leaf Geranium; centre, pink and white-flowering Ivy-leaved—a fine bed. Fourth bed, centre *Trentham Rose* Geranium; two rows of Thompson's King, and two rows of *Variegated Alyssum*.

In looking over this plan, we should say that the plants are more alike in height than in 1861; but it will also be noticed that the tallest are the farthest from the walk, so as to keep the regularity of the slope. We found crossed beds, which, no doubt looked well, but we miss some beautiful mixed beds of Geraniums and Verbenas, which we admired very much. It will be noticed that the parterre is balanced (and the figures are just cut out for being balanced) with similar colours, except the two long ones in the middle, and the four corner beds, though, in our opinion, it would have been as well if the same rule had been applied to them. Very likely, too, we would have balanced both sides of the walk, making uniformly the rule here likewise. This has not been quite discarded, but the prominent idea is to make each parterre a separate garden in itself, and here, most likely, tastes will ever vary, just as one lady may prefer to see a finely matched pair of horses for her carriage, and another may prefer the colour of the pair to be as dissimilar as possible. The parties that pay for the horses and the flower-beds have the best right to gratify their own views on the subject. The *Mesembryanthemum tricolor*, &c., just suit the little beds in the centre, and in bright weather are very sparkling. Some light or white colours more in the centre would tone-down brighter colours at the sides; but the want of whites is neutralised by the masses of bright yellow, such as on the lefthand side, in figures 2, 2, 9, 23, 27, 27, which alike lighten-up and give a balance to the whole

parterre. Still whites in such a bed as 11, or 9, and 23, would be very telling.

We have said so much on the level slope of the beds in such a garden that there can be no mistake upon that point. Some regular abrupt breaks in that level are quite a different thing. At present the unbroken expanse of brilliancy is overpowering; and considering the points of view from the walk, a few stand or rest-points for the eye would be desirable. A vase, or a basket, or a raised bed at 9 and 23, so that the plants should be some 3 or 4 feet above the general level, would accomplish this. Less lofty baskets might be formed at 2, 2, and 27, 27. We throw out this hint with some hesitation, and would be glad if Mr. Kelly would try the effect of tall-flowering plants in 9 and 23, &c., and tell us what he thought of the effect. Such raised beds would, in our opinion, enable us to examine the garden more in detail, make each parterre into several instead of one bewildering and overpowering feature, and in a less degree, but on the same principle, do for them what the raised lofty columns do for the somewhat level splendour of Carton.

Beautiful as these gardens are in summer and autumn, perhaps the most interesting times for the young professional to see them would be March and April. We do not know what are the makeshifts then that Mr. Kelly resorts to, to keep and harden-off gradually such a number of plants as are required for these different gardens, but we have no doubt that many of the makeshifts then resorted to must be very instructive. We can well believe that at such times mind and body are too exhausted in the evening for entering with full zest into the demonstrations and shoutings of welcome, and climbing of the knee of some seven youngsters, "striving who first the envied kiss shall share." Ah, but the thought of these pledges to the future add not only sweetness but energy to toil! It would almost be better than a farce to observe how the attempt to frown-down such child-like merriment and affection would be treated in such a case; as young children, like pet dogs, by the strong instincts of their nature, read every lineament of the human countenance with more unerring accuracy than the most learned physiognomist.

Owing to unfortunate circumstances, which we need not here mention, though receiving the most courteous kindness, we did not see so much of Mr. Littleboy, the land steward, as we should have desired, as he is most justly considered one of the best practical agriculturists in the country, and equally anxious, with his worthy employer, to improve the estate, and improve the condition of the people by increasing the comforts of their homesteads, and giving plenty of employment. Of this we should have known a great deal if we had never seen Straffan; for, from the proprietors of hotels to the drivers of cars, each and every had something to say of the kind noble-hearted owners and their managers. Perhaps it might be only an idea of ours, but yet we could not help noticing often that in such circumstances of kind improving landlords there were manifestations of an enthusiasm of affection, and an earnestness of outspoken gratitude, which are rarely exhibited on this side of the water.

These farms already alluded to are managed by Mr. Littleboy, with the assistance of several bailiffs. On the home-farm twenty-five dairy cows are kept for family use and breeding, and the rest is appropriated to flocks of sheep. Other two farms are also chiefly under grass. Mr. Kelly went with us to Irishtown, which is the principal tillage farm, and where a fine new stead- ing was built in 1856, we understood, from designs and under the superintendence of Mr. Littleboy. The buildings are in the parallelogram form, 242 feet by 147, built in a most substantial manner, and contain stalls for tying-up a hundred cattle and thirteen farm horses, and boxes for fattening twenty-four pigs; and there are two loose yards, each holding twenty cattle, with covered sheds attached. A fixed engine of nine-horse power stands in the centre, and drives the following machinery—viz., threshing-machine, sawing-machine (cross-cut and planing), grist-mill, oilcake-bruise, oat-bruise, pulper for cattle food, and large steam-tub, holding two tons of Turnips, which can be cooked whilst the men are at their meals. Threshing was going on during our visit, and nothing could be more complete; the straw was all carried into a barn adjoining the cattle-sheds, the chaff put beside the steamer, the light grain separated and transferred to a bag, the fine clear equal grain elevated and conveyed along the granary, all fit to be taken at once to market. The oat-bruise, also elevates and turns the bruised Oats into a hopper, and when taken out for the horses a handle is turned, which acts on an indicator in the steward's office, so that he at once knows the

number of feeds taken out in a day, a week, or a month. The cattle-sheds are also complete, forming three sides of the parallelogram, with railroads in front of the feeding-troughs of cattle and of horses, connected with the boiler-house, pulping-house, grain-bins, and hay-house; so that all can be fed expeditiously from the trucks, there being turn-tables at each corner. One side of the cattle square contains twelve loose boxes for cattle, and the remainder are tied up in double stalls. By such means labour is much lessened; but here, as elsewhere, the economising of human labour power, and even the greatly increased activity of the individual workmen, have not tended to diminish but rather to increase the number of workmen employed on the farm. In winter all these stalls are full, and the cattle receiving their allowance of pulped food, cut straw, chaff, &c.

On these farms more than a hundred men are regularly employed all the year round, there being besides a great addition to these in summer, and large companies for drainage and other improvements almost constantly at all seasons. Two blacksmiths, two carpenters, and two painters are kept constantly for routine daily work, and all large jobs are done by contract by other masons, carpenters, &c. A number of cottages are either fresh built or renovated every year, with upstairs bedrooms, &c., that the labourer may not only have "the privilege to toil," but a comfortable home when the toil of the day is over. All these cottages have a bit of land attached, generally ranging from half an acre up to as much, at times, as two acres.

We are averse to speak dogmatically on any subject on which our knowledge is limited, and yet after all first impressions are often the true ones. Our short visit to Straffan left a strong impression on our minds, confirmed by all we heard elsewhere, that like true beneficence which ever carries with it a double blessing, the works in progress were conferring benefits on the employer and the employed—on the former in the shape of an improved estate, and greatly augmented happiness from seeing others happy; and on the latter from increased comfort and stimulated and rewarded industry. There are people on this side of the water who will form no idea of Pat, except as the idle, tattered, ragged fellow, leaning against a gatepost, or holding up the crazy walls of his domicile, as represented by the caricaturist. In all caricatures, there must be a spice of truth, otherwise they would be flat and fail of their object; and in times that are past at any rate, the artist might find no difficulty in obtaining as an object a poor fellow from whom all hope had next to departed, as after every endeavour he had failed to obtain "leave to toil." The caricature, however, is no type of the industrious Irishman. We wish those who still have doubts, could pop in quite unexpectedly as we did, at the Irishtown farm at Straffan, on a threshing day. To say that the men were working like clock-work, would give no idea, unless you associated the regularity of their movements with the rapidity and dispatch of a railway train. We have been in many manufactories and workshops, but we never saw more intelligent activity, except, perhaps, in some large iron-forging and iron-working establishments. All honour, then, to those who are leaving it no longer as a problem to be worked, but as a great fact demonstrated, that the great cure for idleness and its wretchedness are plenty of work and an equitable remuneration for labour.

R. FISH.

DOES APOTHEME ENTER PLANTS?

You will recollect that I started by refusing to accept "J's" conclusions until he gave his authorities, and it is well that he has now done this; and if he writes again on such abstruse points, I hope he will not forget that it is very essential for an unknown writer to give, in this way, some weight to his opinions.

Your correspondent says he regrets "that I would not be convinced by a million experiments," because he thinks "conviction contrary to a foregone conclusion must be impossible" with me, and he then goes on to say that if I am right in this, "Lord Bacon must have pointed out a wrong road to knowledge," &c. Now, I am a steady adherent to Lord Bacon, and will abide by any issue confirmed by him; but I fear your correspondent, like many others, has used his illustrious name as a float when he found himself sinking.

When Bacon told us to "ask questions of Nature," which your correspondent says he did, he did not mean that we should trust to imperfect answers, but that we should wait for the truth, even although "a million of experiments" should fail to elicit it. My complaint is, that scientific writers and experi-

menters now-a-days "jump at conclusions," and give them to a very "gullable" public as authoritative facts. If they would favour us with a little more of Bacon's inductive philosophy, we should be better satisfied.—WM. BAXTER SMITH.

[Here this passage of pens in our columns must close.—EDS. J. OF H.]

POLMAISE HEATING.

I HAVE just read Mr. Robson's remarks upon Polmaise in No. 99. I have had Polmaise at work in my church and school for upwards of ten years, and I think that no system of heating is to be compared with it for cheapness, simplicity, and certainty of action.

I used it for some years in my forcing-houses, but gave it up there, because from want of waterfall it was not in my power to place the stove on a sufficiently low level. Mr. Robson says, "When it (Polmaise) works well, I do not know of any mode of heating that will beat it for the welfare of the plants." I go further and say that I know no mode of heating which equals it, and for this reason, Polmaise is the only system of heating I am acquainted with which keeps up a constant circulation of the air within a house when all external air is excluded. My experience as regards the quantity of fuel required by Polmaise differs altogether from Mr. Robson's, and I have found this method of heating fully as safe as either flues or hot water. The conditions of Polmaise are few and simple, but they must be understood and carried out, or Polmaise will, doubtless, bring those who try it to grief.—W. H.

[We are quite aware that Polmaise answers with those who understand it, and when not too great things are expected from it. It is years ago that we described how well Mr. Lane, of Berkhamstead, made it answer with and without drains, and that without a deep shaft too. All these are secured by the slope of the house, and the pathway forms the drain to bring the cold air to the stove. Something of the same kind will take place in all houses however heated. We are glad you succeed so well with orchard-houses. Yours must be of great size. We would be glad to receive more definite particulars respecting them.]

TREATMENT OF APRICOTS IN BLOOM—VINES GNAWED BY MICE.

THOUGH Mr. Pearson's remarks as to the treatment of Apricot trees in bloom were rather severely criticised, I think there is more in them, and, unlikely as it may appear, in syringing trees in bloom, than Mr. Rivers is inclined to give credit for. Where I live, the springs of 1861 and 1862 were very wet. I believe there was not an entire day without rain during the whole time the Apricot trees against the wall were in bloom, and there were even occasional frosts; yet, notwithstanding this apparently very unfavourable state of the weather, the trees without covering set a fair crop of fruit, whilst those in my orchard-house, which were kept perfectly dry and with an abundance of ventilation (for I attended to them myself, not trusting my gardener), did not ripen a single fruit in 1861, and in 1862 only three or four.

This circumstance leads me to think a gentle syringing might do good rather than harm. My trees look very promising this spring, and I shall try Mr. Pearson's experiment on one or two of them. I am disposed to think none of our horticulturists, even Mr. Rivers, thoroughly understands their treatment in pots; else why under glass are we not as certain of a crop as we are of Plums and Pears?

Your correspondent, Mr. Geo. Burton, to me gives a very unscientific reason with his opinion. How a low barometer in showery weather can make a dry atmosphere is rather inexplicable; if he will test it with the hygrometer he will see. Perhaps I do not comprehend his meaning.

Your regular correspondent, "R. F.," in "Doings of Last Week," reminds me of the mortification I had on replacing my trees in the orchard-house a week or two ago, I had all the pots covered with dry leaves in the autumn; on removing the leaves I found four or five Vines and a Peach tree eaten off entirely by either mice or rats, and four of the Apricot trees, and two Pear trees eaten round, the bark being almost entirely gone for 2 or 3 inches up the stem. Will these live? I have covered the wound with cowdung, then bound it over with moss, which I shall keep damp. There had been both rats and mice in the place; whether

one or both were the depredators I do not know, but am inclined to suspect the latter.—CONSTANT READER.

[The Vines' surviving will depend upon how deeply and how far round the stems the bark has been gnawed away. If in a complete circle and down to the wood, the upper part of the Vines will die, but they will shoot afresh from below the wound.]

PRESERVING GOOSEBERRY-BUDS FROM BIRDS.

I THINK I have at last succeeded in finding a preventive to the destructive ravages of the tomtit and sparrow on the buds of Gooseberry and Pear trees.

Early this spring my fruit trees were attacked, and a great many of the fruit-buds, which are this season unusually forward, were completely destroyed. I immediately procured some guano, and had it broken down to a powder, and sifted through a very fine sieve. I then set a man to water with a common watering-pot some two hundred trees, and as he proceeded with the watering each tree was immediately sifted over, as soon as watered, with the guano. I do not think a bud has since been attacked. It was done when there was no wind; and, consequently, all that did not fall on the trees fell at their base, and will be washed down to their roots the first rain that falls, and promote their growth, so there will be no waste. The whole expense of the man's time and of the guano was about 10s.—something less than three farthings for each tree.

Another suggestion I beg to make is in planting Potatoes. As soon as the tubers are cut sprinkle a little water on them, then throw on them some soot, and stir them over with a spade, so as not to injure them. This prevents wireworm, affords a stimulant to their early growth, and, most probably, prevents disease, as I had last year but about a quarter of a peck out of a considerable quantity at all affected.—W. COPLAND.

SLUGS DESTROYING WORMS.

SEEING that you think the worms eaten by the slug are in a weakened or diseased state, I assure you it is not the case. The slugs catch them when in full vigour both under and above ground. I have worked in different localities almost all round Worcestershire, and a good deal in Shropshire and Herefordshire, but I never saw that sort of slug (a large yellow one) in any other garden than the one I now have the management of; neither did I ever see that slug eat any vegetable. I have a man who has worked on this ground from a boy, he is now turned sixty, and he says these slugs do not eat the vegetables; in fact, he never kills them, nor permits the other men to do so. He first pointed them out, and I could not believe it myself till the men frequently brought me the slug with the worm in its mouth; and I have caught them with their head in the worm-hole, and having a fast hold of the worm, and I have pulled them both out together. These slugs are mostly under ground; yesterday we dug three up, and two out of the three had a worm in their mouth half devoured, the part that was left being in as healthy a state as could be. When they are above ground they are mostly along the walks by the Box-edging, but they are generally in the ground from 6 to 9 inches deep. They seem to suck the inside out of the worm, and to gradually draw the skin in afterwards, and if they lay hold of it in the middle they draw it in double. I have two more men that have worked far and wide in Worcestershire and Herefordshire, both at farming and in the garden, and they say they never saw this sort of slug anywhere else; so that I think it is not a very common kind.—WORCESTER.

IN your Number of the 24th ult. is a reply to a correspondent respecting slugs eating worms. Your correspondent was probably not incorrect in his supposition; one, if not more, species are said to do so. There is a description given of two species of worm-eating slugs in London's "Encyclopedia of Gardening," page 700. One of the kinds he describes I have occasionally found in my garden here, and chancing last night to meet with a specimen I enclose it for your inspection. [It is the same species as that sent by "WORCESTER."—EDS.]

Last year I placed several along with a worm under a propagating-glass to see what would take place. The worm disappeared during the night, but I did not take sufficient care to

enable me to state positively that they must have eaten it. You will perceive that they are not so slimy as the common slug, and that they differ from the slugs with shells (which, by the way, I have never met with near London), in having the shell placed near the hinder extremity instead of on the back or thorax, and not covered by the skin. They are by no means common here; nor, as an old conchologist and collector, have I ever found them anywhere but in my garden.—E. M., *Notting Hill*.

PEACH TREES FAILING IN A COOL VINERY.

THE accompanying letter has just reached us; and as the subject is one of considerable importance, we insert the complainant's letter at full length, with the reply of one of our regular correspondents.

"I should be much obliged by a little information on the probable cause of about three-fourths of the blossom-buds of my Peach trees falling off. The trees were planted at the back wall of a vinery in 1860, in a border about 9 feet wide and 2 feet deep, of good light loam, with a little manure and bones. They made splendid wood in 1861; this was well cut back, and in the following spring, though a good many buds fell a little after Christmas, yet a fair crop was produced. They also made abundance of wood, which was stopped three or four times in the year, and when the wood was ripe the trees were covered with blossom-buds. About Christmas, on washing the trees with Gishurst, a good many of the buds seemed a little shrunk and loose, and since that time they have continued to fall, though they were as healthy as possible last year, and free from insects, with the exception of a trace of red spider.

"After the fruit was gathered last year, the trees were syringed a good many times, and a moderate quantity of water was given at the roots; but during the last four months they have had little or no water, and the border has seemed pretty dry all the winter, though not by any means dust dry.

"As I do not force, the vinery has been cool all the winter, and as the weather has been so mild, the house had generally air front and back, day and night, through the winter, and no fire heat was given except such as a small flow and return pipe passing through the house has afforded, and the trees are now just coming into bloom, though this is very scattered."—J. J.

[Your letter, though carefully written, omits the most important circumstance, and which most probably is the cause of your failure. How many Grape Vines are there against the roof of the vinery of which the Peach trees occupy the back wall? If the glass be pretty nearly covered, it is hopeless to expect Peaches. A few Vine rods may be trained up the rafters, but when they bear and do well there is a strong temptation to allow them to straggle over the greater part of the glass roof, and it is hopeless, then, to look for fruit on the back wall.

We have a large vinery in which Grape Vines are planted in the front in the usual way, and some were also planted against the back wall. The latter have long ceased to be of any use, except at the tops, and we expect your Peach trees have been suffering in like manner. Your mode of stopping the growing shoots three or four times was certainly not likely to produce well-perfected fruit-buds; stopping the gross, rampant shoots, if there were any, very early in the season, and continuing to do so, in order to throw more vigour into the weaker ones, would have been better practice, for buds imperfectly ripened are not likely to produce fruit. Watering is rarely wanted in winter inside a house that receives so little firing: therefore, we think its absence is not likely to have caused the failure.

We would not by any means advise a severe cutting down in winter, such as you say you gave them in 1861. Vines may be cut back with impunity; but Peach trees do not do so well with too much knife work. We hope you did not apply Gishurst Compound too strong. So many causes operate in producing failure, that it is not always to one only that we attribute it. In your case we think it is badly-ripened wood; but if that evil be caused by the trees not having sufficient light, owing to the Grape Vines usurping all the glass, either a part of them or the Peach trees must be sacrificed. Both cannot be fully and successfully cultivated. If, on the other hand, the bad ripening arose from the growth being prolonged in the autumn, the leaves would hang on late, and the tip ends starve rather than mature.

You will most likely be able to judge which of these evils

your trees suffered most from, and from this, in addition to the advice given from time to time in our Journal, on the management of the Peach, you will be able either to find a remedy, or if the Grape Vine be in fault, it then rests with you, or those

with whom you act, which of the fruits you are willing to sacrifice. A few Vines against the rafters of a Peach-house may be tolerated, but too many is] at variance with the well-being of everything else.—J. R.]

PROTECTING FRUIT TREES.

BEING an amateur and not keeping a gardener constantly, I have experienced some difficulty in coming to a conclusion as to what is best to adopt in order to give my young wall trees the necessary protection with little trouble, and which at the same time would be economical and lasting. I have been scheming to accomplish these objects, and the result is what I have shown upon the accompanying sketch, which almost explains itself.

The frames I have made are five-eighths of an inch thick and 3 inches wide, ripped off a deal. The upper shutter is made of two leaves, half an inch thick, of deal ledged together (of course this might be made a light frame filled with straw like the lower one if preferred). It is hinged to the frame by three pieces of leather being nailed to them. The top is fastened, when closed, with a common wood button, as at *a*, *a* in *fig. 1*. The lower move-

able frame is made in the same manner and with the same scantling as the frame itself. It is hinged at the bottom with three pieces of leather like the top shutter; but, instead of plain boards as in the upper shutter, this is filled in with long straw laid in between two spinyarns which are secured to the frame: thus the straw is a kind of thin thatch, protecting the trees from rough wind and frost but not excluding the air.

b b b *Fig. 2*, are pieces of ropeyarn tied to both the moveable and fixed frames or shutters at the tops, and of such lengths as to determine the angle at which the shutters will stand when open. I have so fixed mine that when the morning sun is shining—say 10 o'clock A.M., little or no shadow is cast either upon the wall or tree by them. This hasty and rude description will, I hope, have made the scheme clear to you.

The frames having been set against the wall where they are required, the top is kept fixed and secured by the two splines $1 \times 1'$, *fig. 3*, being tied by a cord to two nails or staples in the wall. The bottom of the frame is secured by two stump stakes.

Being fixed I need scarcely say, that to open the frames all that is required is to turn the button, and the moveable shutters are opened and fall to the required angle. To close them, of course the reverse operation has to be done. Thus a few minutes suffice either to open or close them—an operation of no labour, quite in the compass of a lady's hand. Thus you see the trees may either be thoroughly protected, or fully exposed at pleasure.

When the season is over I intend to have my frames, which are made of a convenient size for the purpose, taken away and packed under cover for another season. I see no reason why

they may not last for a number of years in good condition. Fresh straw, perhaps, in a few years may require to be put in, but this is a very trifling matter.—H. G., Ipswich.

P.S.—May I ask some of your gentlemen's gardeners who contribute to your pages, if they will be so good as to give me their advice as to whether I ought to keep back my fruit trees by shading them or open the frames to give them the full sunlight? The scheme above described gives me easy means to do either. The trees are forward, and, probably, before the month is out we may have coarse weather. I have been keeping them somewhat sheltered. I suppose when the proper time arrives they must be fully exposed.

[We cannot give you a better reply than is contained in this extract from a communication sent to us by the late Mr. Errington, one of the most successful of fruit-growers:—"My Peaches this year, on a W.S.W. aspect, have been abundant. Those on a due S. and S.E. failed. This aspect has something to do with such result, because I have always observed that the blossom opens later there, and the leaves do not blister so much. This last winter, however, remembering what you stated about retarding the blossoming of Peach trees by heaping snow about their stems and over their roots, I adopted every mode I could think of to retard my trees in blossoming on that W.S.W. wall. I unnailed them, and shaded them from sunshine throughout the winter, keeping them covered with wet straw and mats, but exposing them whenever the weather was cold during the day. With the same object I laid bare the roots, and I pruned late. My reward was having the trees bloom fully a fortnight later, and having a good crop. When in bloom they were protected with nets the same as those on the S. and S.E. walls; but on these I had scarcely a dozen Peaches from twice as many trees."

CROCUSES DESTROYED BY SPARROWS.

I PERCEIVE that one of your correspondents asks the cause of the destruction of his Crocuses. No doubt, as you say, they have been destroyed by the sparrows. I have a large quantity of Crocuses, and the sparrows have played sad havoc with them this year, as they have come early into bloom. But there is a simple remedy, which in my case has never failed—namely, to place white cotton or white worsted close to the Crocuses, either round the clumps or lengthwise with the border, supporting and placing it in such a manner that the birds cannot pluck the flower without touching the thread.

I have found mice very destructive in burrowing and eating the roots early in the season; and there seems no better trap than the old-fashioned one set with thread, which they have to nibble before getting guillotined. The traps can be put under old pots or boards to keep the rain off; and there is nothing better than baiting with oatmeal.—JOS. LLOYD PHELPS, *Lee Crescent, Edgbaston.*

WINTERING OLD VERBENAS.

I OBSERVED that you mentioned on one occasion how very difficult it is to take up Verbenas from the beds and keep them. I beg to state my success as regards this matter.

My plant was a fine healthy one of the *Géant des Batailles*. I first proceeded to cut a great portion of the branches away, leaving about 6 inches of each. I put the plant, in a six-inch pot, in a shady part of our conservatory, for about a week, then plunged it in a cold frame, in tan well watered, facing the sun, and kept the glass covered. My plant is now a strong one, with some nice shoots just fit for cuttings, and it will soon bloom if I choose to let it go on. I think this a very good plan if you desire to have good plants of Verbenas in bloom early in the season.—AN ARDENT ADMIRER OF THE VERBENA.

[No doubt your plant is a good one, but a cutting struck early in autumn, and topped, and having the attention you gave to your favourite, would also now be a fine plant. Your experience is a proof of the truth of the saying, that there is hardly a rule without an exception. We have kept old Verbenas over the winter, but in general young plants are better every way.]

GARDENERS' COMPANY.

GARDENERS were once a corporate body, as their charter plainly sets forth. That charter never was of much value; for, like all protectionist schemes, it failed to infuse new life and vigour into the members, and lulled them into the sleep of false security. Opposition is the soul of progress, and competition causes improvement. That the charter was ineffective from the first may be inferred from the fact that a second charter was granted amending the defects of the first. This also came to nothing, for a warrant was issued by Charles I. calling upon magistrates and others to enforce the charter.

The first charter was granted by James I. in 1616. The charters are preserved at the Public Record Office; and the warrant is private property, late in the possession of W. Paxon, Esq., 9, Terrace, Gray's Inn Lane, Holborn, London. "The Worshipful Company of Gardeners," incorporated by James I., A.D. 1616, the seventieth on the City list, consisted of "The Master, Wardens, Assistants, and Commonalty of the Company of Gardeners of London." They were governed by a Master, two Wardens, and a court of eighteen Assistants. Their income was raised by fines and fees, and quarterly subscriptions of 2s. They had no hall.

Could the charter be revived? No. Before that can be done we must have a class of men conformable to the charter. The charter has certainly done no good, and is so outrun by the time that its working would be obnoxious: therefore the charter is a memorable relic of the past and nothing more. But—we hesitate to put the question—could not men having interests in common form a company, become united instead of divided, and aid their mutual needs?

Nobility, gentry, and clergy have associations, merchants their chambers of commerce, farmers their clubs, common tradesmen and workmen their unions; and all men, except gardeners, have institutions more or less upholding their interests and advocating their cause. Surely men having their periodical publications can form a Company useful and honourable. That they

have intelligence is not doubted, but each individually is striving to advance his own interests irrespective of the consequences to his brethren. These causes, with the present system of garden-making, have made gardening what it is—no profession. Owing to gardeners granting free trade—for they were the first free-traders in the country—they let in all classes of the community. If a man only works in a garden a few years—is persevering, sober, honest, and industrious—gives Mr. Head-gardener satisfaction, he is soon sent out as a gardener. Such systems of garden-making have glutted the market. There is no difference between a man who has gone through a course of study and served an apprenticeship and one who has not; providing that they do for the time being work in gardens, both are gardeners.

A gardener according to the charter is a different man. He must serve an apprenticeship, give proof of his competency, and be an enrolled member of the Company before he is permitted to practise. All gardeners must conform to these regulations—that is, within six miles of the City of London, according to the charter, or they would be liable to injunction, fine, or punishment. That was a protectionist scheme then, and thought to be an effectual barrier against quacks; but alas! the quacks eat up the profession. What a stir there would be in the great city if the charter were now enforced; and there is nothing to prevent it, providing there are twenty-one men in London who could conform to the charter, which is disputed, for the charter is as perfectly legal as it was on the day it was granted.

We have six classes of gardeners—viz., 1st, professional gardeners; 2nd, nurserymen; 3rd, florists; 4th, seedsmen; 5th, market-gardeners; 6th, jobbing gardeners; and another class, neither gardeners, cowmen, nor grooms, and yet a little of all: therefore I propose that they be termed utilitarians; but as I ignore their claims to the title of gardener I propose to make a special provision for them hereafter. The first six in 1841 numbered respectively:—Gardeners in England and Wales, 45,751; Scotland, 6277; Ireland, 7422. Nurserymen, England, 1481; Ireland, 121; Scotland, 141. Seedsmen, England, 771; Scotland, 135; and Ireland, 88. Taking for granted that these three denominations represent the six above mentioned, which is not improbable, for all men that work in gardens are styled gardeners, and all florists are nurserymen, we have a grand total of 61,389. In 1851 they were collectively 74,837; and if we measure the increase aright, we should have no less than 80,000 in 1861. Not less than 60,000 of these are dependant on wages; and if we reckon an employer to every six we have 10,000 employers, which we add to the figures before named, and we have 90,000. Then we have amateurs numbering not less than another 10,000, which raises the figures to 100,000.

Could not these various classes be brought into friendly intercourse, united instead of divided? I have long—though but a juvenile—had an idea of a Company which would combine the main characteristics of our national constitution, as employers and amateurs the House of Peers, and nurserymen, gardeners, &c., the House of Commons; both being ruled by an arbitrator or president, not a Yankee, who would exercise his prerogative in matters of dispute between the Houses. The President to be chosen by the members of the Company in the following order:—employers, 4 votes; amateurs, 2 votes; and gardeners 1 vote each respectively.

The Company is proposed to be called "The Company of Gardeners of Great Britain and Ireland."

No gardener shall be admitted a member of the Company unless he can write in a clear bold hand satisfactory answers to the following questions:—1, Name in full; 2, where born, and date; 3, that he has worked in a garden seven years with the intention of learning horticulture and following it as a business; 4, name the places where the seven years were spent; 5, can the applicant have a good recommendation from present employer?—the address of his employer must accompany the declaration, so that the declaration can be verified if disputed by members; 6, that he is willing to pay all fines, dues, and subscriptions, and to further the interests of the Company if elected a member. Nurserymen, seedsmen, florists, market-gardeners, and jobbing gardeners shall make their declaration in like manner, substituting the term of nurseryman for gardener and so on, leaving out the fifth query.

Candidates may, if they think proper, state whether they understand keeping accounts and mensuration of surfaces and solids; whether they can make ground plans; give plans and

specifications for horticultural structures, and useful or ornamental buildings. In botany, to name nine plants in ordinary cultivation out of every ten correctly; to understand vegetable physiology as far as regards the germination of seeds, formation and development of plants; entomology, in its relation to the ravages of insects on vegetation; and pomology, so far as to name and distinguish nine fruits in every ten of such as are commonly cultivated.

Persons answering these queries will be called upon to submit themselves to an examining-board appointed by the Company within two years from the date of their admission. Parties signing the declaration and refusing to be examined to be discarded the Company; but those who answer the call, though unsuccessful, to continue members, but their declaration on application paper to be scratched. Those who successfully pass the examination to have medals of bronze, with the emblem of the gardener on one side with his motto, and the emblem of the country to which the medal belongs; and on the other the value, as first, second, or third. A certificate to accompany the medal, duly signed by the President or his deputy. The value of this is too apparent to need explanation.

Candidates may state if they are a correspondent of any horticultural journal, and which, naming half a dozen of the subjects which they have written upon, if so many; if less, they must not sign, for it is evident they are not professed writers. They may also state whether they have been successful exhibitors, when and where; naming a few instances, and the subjects. Candidates may exercise their discretion about answering these queries.

Candidates giving satisfactory answers to the numbered inquiries shall, by paying an entrance fee of 5s., be registered members of the Company; amateurs, an entrance fee of 10s., their address and remittance shall be a sufficient guarantee of their respectability; employers—and I make a great point of their co-operation—without them we can do nothing, £1.

This entrance money would realise—employers £10,000, amateurs £5000, and gardeners £20,000, or in all £35,000. Now, as gardeners are so peculiarly liable to rheumatic diseases, rendering them unable to work in their old age, and not a few are cut off in the prime of life, leaving a wife and several children destitute—for those reasons we would place the money in the Government Funds, which would afford £1050 yearly, and allow of twenty-four married pensioners being kept in decent circumstances, instead of pining in the poor-house after they have been disabled through no fault of their own, and twenty-four widows or widowers. The former should have £20 yearly for life, or until such time as death severed them, when £13 15s. would be allowed to the survivor. The voting for pensioners to be as follows:—Gentlemen and ladies 4 votes, amateurs 2 votes, and gardeners 1 vote.

Employer members to pay £1 annual subscription, amateurs 10s., and gardeners 10s., or 2s. 6d. per quarter, payable in advance.

Two shillings and sixpence of employers' subscription should be appropriated to the uses of the Charity Fund, which would yield £1250, whereby twenty-four married pensioners and twenty-four widows or widowers could be elected pensioners. It is expected that gardeners would not hesitate to contribute to this fund, say 2s. 6d. yearly; and as they would have precedence over non-subscribers they ought, one and all, to subscribe, which would be ample to keep all their own poor without troubling ratepayers. In that case there would be 384 pensioners on the list.

Seven shillings and sixpence of employers' money to be employed as follows:—One-half, £1875, to be distributed to successful essayists; £78 2s. 6d. to be given to each district (mentioned hereafter), and that, equally divided, again given to the branches, at each of which a prize should be offered for the best essay on whatever subject the employer members shall name, to be competed for by members of the branch. The other half, £1875, to be appropriated to the printing of essays, which shall be at the rate of two for each district, and they shall be chosen by vote. The essays not to exceed 12 foolscap pages. Employers to have copies of the essay volume free, but members to pay 1s. for it. The printer to sell any number he chooses after the above regulations have been fulfilled.

I now come to write of the meeting-places of the Company. Supposing the United Kingdom to be divided into districts—viz., twenty-four for the whole kingdom—i.e., fourteen for England and Wales, four for Scotland, and six for Ireland;

according to this arrangement each district would comprise 4166 members, and the districts being divided into branches of 63 members each, we have 1612. Thus the head quarters of the Company would be in London for England, Edinburgh for Scotland, and Dublin for Ireland; districts to have their head offices at the most central part of the district, and branches to be distributed according to the number of members—fifty to form a branch.

Each district office and branch shall find, furnish, and pay for hire of its own rooms, and all accounts thereto belonging. Each branch to forward 7s. 6d. for each member to the district office, which sum is to be forwarded by it to the head office of the Company, where it shall be applied to the printing of the Company's Journal, and publishing, and other expenses connected therewith, and for those purposes only. The Journal to consist of twenty-four pages of printed matter relating to gardening or horticulture, containing the best of the papers read at meetings of the Company, novelties exhibited, awards, state of weather and vegetation, and communications. Free discussion should be allowed in its pages to members, and reports given on the general business of the Company. I think terms might be come to with the gardening papers of each country, to do the printing for the Company on the condition named hereafter, with power to receive pay for advertisements, an unlimited number, and to sell the Journal at a reasonable price to non-members.

Each member paying 7s. 6d. to the Journal fund would raise a capital of £37,500, of which £8750 should be given to the London office, for the purchase of plant and hiring of offices for the transaction of business connected with the Journal, and other matters; £3750 to Ireland; and £2500 to Scotland. Besides the grant for formation of offices, &c., a further grant shall be made as follows:—Head office of England, £13,100; Ireland, £5700; and Scotland, £3700; for which each member is to receive, free, a copy of the Journal of the country or head office to which his district is attached.

Two shillings and sixpence of each member's subscription to be appropriated to pay for hire of rooms, lighting and warming in winter, &c. The branches shall select their own meeting-places—that is, the most convenient situation—and make their own agreements, for which they alone will be responsible. No doubt there would be great difference of opinion about the meeting-places. Some would say a club-room at a public-house, for the sake of the friendly glass and merry chat; but a public-house is the worst place imaginable, for our proposition is intended to enlighten the mind, to cultivate the intellect, and to improve the man's social and moral condition.

A school-room would be the most economical meeting-place, and one every way calculated to answer the purposes of the Company. Fortnightly meetings should be held, when a short paper would be read, or of such a length that not more than half an hour would be occupied in reading it. Ten minutes to be allowed any member for discussion on the paper. The paper to become the property of the Company. New plants, fruits, and vegetables to be exhibited, for which certificates may be awarded if the subject merited the distinction. Extraordinary productions, and specimens of subjects relating to gardening, might be exhibited, for which a vote of thanks may be given. The meetings to commence at seven o'clock in the evening.

In connection with the Company would be an exhibition fund, in which all could join, non-members as well as members. To this fund members would pay respectively—employers 10s., amateurs 5s., gardeners 2s. 6d., and non-members of the Company any sum not less than 5s.; tradesmen 2s. 6d., and working men and cottage-gardeners 1s. I calculate the subscriptions would realise £50,000, of which £20 to be granted to each branch, £500 to each district, £3760 to the central (or head) of England, £1700 to Ireland, and £1300 to Scotland. Thus each branch would have its exhibition, once yearly, each district two, in May and September, which would be held at different places, the places being chosen by the subscribers; and the central four in April, June, August, and October—also held in different places, these being chosen by the subscribers.

Subscribers of 10s. to have three tickets to attend all the shows of the central, district, and branch of which they are members; those paying 5s. to have two tickets for the central, district, and branch; 2s. 6d. subscribers to have one ticket for central, two for district, and three for branch to which they are attached; 1s. subscribers to have one ticket for one central show, one for district, and two for the branch to which they belong.

The anniversary of the Company to be held at the October meeting of the central, when an account of all the districts would be given, and districts to audit their affairs prior to the meeting. At the end of every seven years there might be a meeting of members from all parts of the kingdom, and an exhibition open to all the world, so that the year of jubilee might be celebrated with *éclat*.

Also in connection with the Company a benefit society might advantageously be formed similar to others, and I have no fear of employers not aiding the movement.

The Company might allow utilitarians to become members, if they thought proper, at the same rate as a gardener, and their employers also, but with this reservation: No utilitarian shall be allowed to take the title of or practise as a gardener, unless he make application as for a gardener and has been enrolled a member by the votes of the branch members, which must be confirmed by the district, and signed by the President. Neither shall a gardener change at will from a gardener to a nurseryman, and *vice versa* throughout; but he, they, or any member must give notice of the proposed change, and have the Company's permission to make it. Offenders to be discarded the Company, to forfeit all privileges and all moneys paid, and to pay all dues.

I cannot forbear proposing that cottage-gardeners be allowed to attend all meetings of the Company, and to pay a nominal subscription, say 1s., but to have no other privileges, except loan of books or papers.—G. A.

[We have inserted this communication as an evidence that there is a spirit abroad among gardeners for the improvement of their profession. It is a communication from a practical gardener; and though the calculated subscriptions are wildly extravagant, and some of the proposed proceedings undesirable, it may serve to awaken attention to the subject.—Eds. J. OF H.]

LANCASHIRE DISTRESSED WORKINGMEN BOTANISTS.

I HAVE received, since the last notice I gave, from Lady D. Nevill £1, which she kindly sends every month; also from a working gardener 2s. 6d. (monthly); from J. R. £1 10s.; from Miss Sloane £1; Mr. Marlow 5s. I have also received a collection of choice vegetable seeds from Mr. Henry Watkinson, of Manchester, which my friend Mr. James Wild, an old florist, kindly distributed amongst forty-one poor cottage-gardeners who are in distress by the cotton panic.

There is a well-conducted young man here who has a good knowledge of both systems of botany, and he would be glad to learn to be a gardener if an opening could be made for him.—JOHN HAGUE, 36, Mount Street, Ashton-under-Lyne.

WORK FOR THE WEEK.

KITCHEN GARDEN.

THOSE who have fully attended to former directions respecting the manuring, trenching, and pulverisation of the soil will now amply reap the benefit of their past labours; they will have a greater depth of staple in proper condition for nourishing the roots of plants, at the same time the ground will work with much greater facility. This has been, and still is, a most extraordinary season, and in the event of our being visited by sharp frost, either this or next month, the result will be calamitous in the extreme. Some are sanguine enough to predict that we shall have no frost this season, and let us hope they are true prophets. *Artichokes*, make new plantations, and fill-up old ones. *Beans*, sow in a sheltered situation, and transplant them in pots or boxes. *Beet*, sow for a principal crop. *Carrots*, sow in the open ground, and thin-out those in frames. *Horseradish*, plant, if there is not sufficient in already. *Leeks*, these should be sown for the main crop, if not in already. *Lettuce*, sow, and harden-off those in frames, to be planted-out as soon as fit. *Onions*, the main crop, if not already sown, should now be put in. *Peas*, sow several varieties for successive crops. *Spinach*, sow a few more rows. *Turnips*, sow early Dutch in a warm situation. Take every suitable opportunity of surface-stirring, hoeing, forking, trenching, and subsoil-trenching, turning in all refuse vegetation, and taking care that no useless crop is robbing the ground. At this busy time both the eye and the mind must be active if any ample amount of produce is looked for in return for the labour bestowed on the preparation of the soil.

FLOWER GARDEN.

Proceed with the operations that involve the necessity of wheeling or removing earth. Complete all planting. March winds are often destructive if the precaution of renewing old stakes and strings rotted by the damps of winter is neglected. Prune Roses generally, and dress the beds with rotten manure. In completing the arrangement of the flower garden duplicate herbaceous plants may be found; these can be distributed about the pleasure ground with excellent effect. Roll and sweep lawns, cleanse and turn gravel walks where necessary. To eradicate weeds there is nothing like handweeding. Fork-over flower-beds, and get them in a wholesome state to receive the delicate plants intended for them.

FRUIT GARDEN.

Planting, pruning, and nailing should now be forwarded as much as possible. These operations cannot be finished a minute too soon. The sap having now commenced its ascending course, broken-off flower-buds and injured shoots will be the certain consequence of delay and neglect. Continue to protect the bloom of Peach, Nectarine, and Apricot trees. Take advantage of dry weather to draw away the soil from the stems of Gooseberries and Currants with a hoe to about 2 inches in depth and over a diameter of 2 or 3 feet, for about this time what is generally termed the Gooseberry caterpillar will begin to be on the alert; sprinkle over the space cleared some soot and wood ashes, returning the earth with the back of a hoe or rake. This is not only a preventive to their ravages, but acts as a stimulating manure to the trees, and the extent to which it may be applied will be very perceptible throughout the season. The early season will render immediate preparations for grafting necessary.

STOVE.

Cuttings of all free-growing softwooded plants, such as the different showy varieties of *Justicia*, *Begonia*, *Aphelandra*, *Poinsettia*, &c., will strike readily in a brisk bottom heat. They will, if well managed, make useful and handsome plants for blooming next autumn and winter. *Achimenes* and *Gesneras* may be repotted, and others, to succeed them, put in. Stove Orchids will be benefited by a little additional warmth and moisture; when it is desirable to prolong the blossom for a considerable period the plant may be removed to a cool house.

GREENHOUSE AND CONSERVATORY.

Some of the early-forced *Camellias* and *Azaleas* will now begin to fade. If they appear exhausted do not force them to expand their last flower-buds, but rather remove them before they expand, in order to invigorate the plants a little. Any *Camellias* that are becoming misshapen or too large may now be cut-in, and if afterwards placed in a nice growing moist temperature of from 55° to 65° they will soon break afresh, and make fine plants. Syringe them daily once or twice, and if necessary give a little manure water. The same treatment is applicable to Indian *Azaleas*, and if the shoots are stopped once or twice during their growing season fine bushy plants will be produced, which will ripen their wood and be ready to bloom in December. All the specimen plants in these houses should be carefully examined to see that their roots are in a proper state with regard to moisture and the drainage clear. *Ericas* to be top-dressed or repotted. *Tropæolums* will require attention. *Pelargoniums* and *Calceolarias* will require increased pot-room. *Dahlias* to be put in action. *Fuchsias*, *Cupheas*, *Salvias*, *Bouvardias*, and other plants for the parterre to be encouraged to afford cuttings. Remove all decayed leaves and flowers, and attend to order and neatness.

PITS AND FRAMES.

Admit abundance of air, water carefully, and continue protection at night as long as there is any danger from frost. Attend to the young stock which is intended for bedding-out, and go on propagating stock for the flower-beds as it can be procured. Top-dress *Auriculas*, *Polyanthuses*, and *Carnations*. W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE weather being so mild, planted out in well-aired thoroughly-pulverised soil a good breadth of Potatoes, also Cauliflowers from pots and thinnings from hand-lights, leaving five in each of the lights, watered them, and top-dressed with rich material. Sowed a few more Peas and Beans. Sowed Sangster's No. 1 in boxes on the floor of a Peach-house, to be

transplanted for the first crop out of doors. Planted Garlic, Shallots, and young Onions. The former are placed in drills about half an inch deep and a foot apart, well firmed with the fingers and thumb, and a little charred refuse thrown over them; the latter are fastened in the ground merely by the roots. If a little of the neck is buried likewise, you have little chance of good early bulbs. Sowed Spinach, Radishes, and Turnips in the open air. Sowed also a few on the south side of a raised bank to receive some protection, to have them early, being doubtful if we can give them a slight hotbed this season. The white Turnip Radish is useful for early work. It serves in many cases for soups, &c., instead of early Turnips, and we have found many clever people who did not know the difference on the table, and they can be had several weeks before Turnips. Generally sow a few White Dutch Turnip and Snowball for the first, but always afterwards the American Red-top. Our *chef* says they are often more delicious than a moderate Melon.

Gave syringings of clear soot water to Dwarf Kidney Beans in pots, to keep away all trace of thrips and spider. Sowed more in boxes for succession. Planted-out strong Cucumber plants in the frame heated chiefly with leaves, which are now hot enough. Was obliged to turn them over in several places and strew with quicklime, to destroy a lot of disagreeable funguses that were running among them. That is an evil to be avoided when leaves are chiefly used. When mixed up with hot dung so as to cause a strong burning heat before being used, there is little danger of these funguses, as the spores are pretty well killed. We have known Melons and Cucumbers on beds where a mild heat was given by leaves much injured by these spawns getting into and taking possession of the soil. We have planted these Cucumbers in pure loam from the roadside without any admixture whatever. I am very anxious to remove all trace of the Cucumber disease, which has now troubled me several years in pits, frames, and out of doors. Last season we were little troubled with it until Cucumbers became plentiful even out of doors, as the early crops were everything that could be wished. Vegetable Marrows were also similarly affected, whilst as yet Melons have showed no trace. We have found no remedy like fresh soil and frequent planting.

Top-dressed and put small twigs to Tom Thumb Peas in pots, and removed them from frame into a place where they can be protected before it is convenient to move them to an orchard-house. Stirred the soil about a row in front of an orchard-house.

FRUIT GARDEN.

In addition to the routine of previous weeks, moved Strawberries from the back of a vinery, where they were too much shaded, to the back of a pit, where they can have full light. We always think the fruit ripened in the shade is deficient in flavour. Forked the ground among Strawberries out of doors—that is, merely for an inch or two. Cleared away all the stubble, &c., in which fruit trees had been packed in the orchard-house, and will, if possible, defer setting them out for the summer until we have a wet day. Sometimes we are apt to defer too long for such weather; but as we never like to see a man get wet, there must be a little study of such matters. The early-pruned trees on walls and in pots (Peaches) will want going over again, as there is a greater deficiency of wood-buds this season than usual. What we are pruning now will escape that, as the wood-buds are now perceptible, so that there can be no mistake. Pretty well finished pruning Peaches and Apricots out of doors. We find that some trees that had nothing done to them in the winter are more free from any traces of insects than those we washed and took great pains with. Painted the trees where the blossoms were not advanced enough to permit of its being done safely, preferring the painting to be done before the buds begin to swell much.

A correspondent is in trouble about his Peach trees, as the bricklayers some time ago had spattered them all with lime, which he cannot remove, scrub as he will. We presume it was spattered on before the buds were far advanced, and in that case would do good rather than harm; it would become mild chalk in a few days, would seal up what eggs of insects there might be, and will scale off of its own accord during the summer. There is, therefore, no need, but the reverse, for the attempts to remove it.

As soon as the fruit seemed set in the Peach-house, before the blossoms had dropped, we gave the trees a thorough drenching with the syringe, as, besides a few black beetles, there are signs of red spider on the young shoots, which we never noticed before at this early season; and this after the care bestowed in tho-

roughly scrubbing and washing every part of the house, and removing the surface soil. The watering over the surface of the trees, shutting up early, and sulphur on the heating pipes, will, we trust, soon remove all trace of this red-coated little gentleman.

Moved all the Strawberry-pots from orchard-house, making a bed of them in the open air, and if a sharp frost should come will scatter some straw or rough hay over them. Tied-out Vines in first house, temperature at night averaging 60°, in dull days from 65° to 70°; in bright days, 75° to 85°, with a little air given early. In earliest small six-foot Vine-pit, the temperature is from 65° to 68° at night, and is raised in proportion during the day. The whole of the outside walls of that pit being thatched with straw, comparatively little fire heat is required.

Figs are beginning to push in Fig-house. Pinched the terminal bud, pushing, through the middle with finger and thumb, when it was desirable to throw back the sap into the incipient fruit at the joints; when the shoots push again there will likely be several instead of one, and the most suitable one can be retained. Have still kept the laurel branches on the Figs out of doors, as we may yet have a severe frost, and the shading at present prevents the young fruit pushing so as to be injured. In that case we generally nip across the terminal bud when it swells, as there is no chance of obtaining a second crop out of doors. This stopping throws back the sap on the different joints of the shoots. When long-jointed shoots are made, the tree should be lifted, the roots cut, or the branches ringed. Some time ago I mentioned an instance of Figs proving extra fruitful out of doors owing to the stems being gnawed with mice.

ORNAMENTAL DEPARTMENT.

Scrubbed walks, rolled lawns, pruned Roses, planted edgings of Cerastiums, &c. Find that fine edgings of the white Campanula carpatia are pretty well done for, from the long-continued damps of the winter; wish we had lifted it, and set it in a dry place above ground, as it is a beautiful compact plant. Find, also, that the taller kinds of Lobelias left out have perished from the same cause. Made preparations for sowing lots of seeds prepared the other week. Filled the four lights with Calceolaria cuttings from nipping-off the points of those struck in autumn. Cannot perceive how "ANTIPATHY TO BOTH" can find fault with our mentioning that a piece of Aurea floribunda is not quite so good as the rest of the Calceolarias, more especially as the cause was also given—namely, the using of old effete soil for putting the cuttings in. These might stop a little longer before being moved; but the rest, even after stopping, must be put out soon, or they will injure each other. The cuttings inserted in the frame-beds will stand about 1½ inch apart, and will remain there until wanted; but as soon as rooted the frames will be lifted off for something else, and partial protection given to them.

As soon as possible a bed or two in a similar manner will be made ready for Verbenas cuttings; and generally these plants, from such cuttings left in the bed until wanted, will thrive as well, if not better, than those that have received ever so much attention from separate potting, &c.

Proceeded with potting all plants needing it. Brought soil into sheds for the purpose of being dried and aired, and in all earth-pits and temporary places for protecting bedding plants had them cleared, made ready, and the soil turned over a few inches to be heated and mellowed by the sun's rays. If we do not plant-out until next week will likely turn these beds over several times, so as to dig down or cover-in the soil acted upon by the heat and light of the sunbeams. We do not mind a depth of from 3 to 6 inches for planting-out Calceolarias; but we like a hard bottom and a depth of only about 3 inches for Scarlet Geraniums, as they lift better the more shallow they are planted.

These minutiae are of little moment for those who have a place for everything and know nothing of cramming, but they may be useful to those who have little glass and yet aim at making the most of it.—R. F.

TRADE CATALOGUES RECEIVED.

W. Bull, King's Road, Chelsea.—*List of New and Rare Plants.* 1863.

Downie, Laird & Laing, 17, South Frederick Street, Edinburgh, and Stanstead Park, Forest Hill.—*A Descriptive Catalogue of Florists' Flowers, &c., &c.* 1863.

Francis & Arthur Dickson & Sons, 106, Eastgate Street, Chester.—*Catalogue of Select Agricultural Seeds.* 1862.

G. W. Hay, Church Street, Worcester.—*Spring Catalogue of Kitchen Garden, Flower Garden, and Farm Seeds.*

Robert Kennedy, Conservatories, Covent Garden.—*A Catalogue of Ferns, Exotic and Indigenous.*

Peter Lawson & Son, 28, King Street, Cheapside, London.—*Catalogue of Agricultural Seeds.* 1863.

John Norse, Dursley Nurseries, Gloucestershire.—*Spring Catalogue of Cuttings of Dahlias, Verbenas, Geraniums, and other Bedding Plants, &c.*

Edward Taylor, Malton.—*Catalogue of Agricultural, Garden, and Flower Seeds.* 1863.

Toole & Company, Westmoreland Street, Dublin.—*Spring Catalogue of Vegetable, Flower, and Agricultural Seeds, Plants, Roots, and Implements.* 1863.

TO CORRESPONDENTS.

*** We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the "Journal of Horticulture, &c.," 162, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

We cannot reply privately to any communication unless under very special circumstances.

ROSES MANURED WITH FOWLS' DUNG (A Young Gardener, Dublin).—So far from doing the trees any injury it will benefit them, and you may water them with a weak liquid manure made of it—a peck to thirty gallons of water as soon as the flower-buds appear.

MAKING SODS INTO MANURE (J. L.).—Do not pour sulphuric acid over them, for it would take a vast quantity to kill the weeds in them. You had better have them mixed with lime and salt, turning the mixture two or three times before using it as a manure. A bushel of salt and a bushel of lime to twenty bushels of sods would not be too much.

INSECTS IN ASPARAGUS-BEDS (A. B.).—They are Millipedes (Julus), and one Centipede. We believe that they cause no injury to plants, but feed upon decayed vegetable substances.

WHITEWASH OVER WALL-TREE BLOOM-BUDS (R. N.).—If the whitewash was put on before the buds were much swelled, it would do good instead of harm. Do not meddle with it, it will fall off during the summer.

GRAFTING YOUNG ORANGE STOCKS (W. B.).—Your best plan is to form a mild hotbed, with a bottom heat of about 75° to 80°. Nip the point off your plants, set them for a week in the bed, then take them out a few at a time, and, as near the soil as possible take off a slice of 2 inches long or so from the side of the stock. Do the same with a scion, tie them neatly together, cover with a little clay, or grafting-wax, and syringe every day to keep a close moist atmosphere. They will soon take.

BOTTOM HEAT (N.).—Bottom heat is the heat given to beds or pots from beneath, either by hot water, or by dung, or by fires. We think there must be something wrong in your chamber. Is it close all round? If so, the heat at the slate may at times be too great. We would advise you to put 6 inches of open rubble over the slate, and you might have two or three round small drain tiles in every light, set upright over the rubble, and the upper end plugged. This would help to diffuse the heat equally through the soil, and you can pour water into these tiles so as to have a moist heat at bottom when desirable. If the soil gets caked against the slate the heat will not rise freely, and if it becomes sodden like a morass the plants will not thrive.

TRANSPLANTING CROCUSES AFTER FLOWERING (Felixstow).—By taking them up with as large a ball of earth as possible they may be removed to some other place, and there left to ripen; after which they may be taken up and kept until September, and then planted where wanted next year. They suffer a little by this treatment, but if carefully managed they flower pretty well the following year. Sanders on the Vine will suit your purpose, and give you all the information you require.

GOOSEBERRY CATERPILLARS (J. F.).—There are two caterpillars that attack the leaves of the Gooseberry. The most usual depredator is green, spotted black, and is the progeny of the Gooseberry Saw-fly, *Nematus trimaculatus*. The other caterpillar is yellowish-white, with an orange stripe and black spots. This is the progeny of the Magpie Moth, *Abrazas grossulariata*.

PROPAGATING CLEMATIS (Wyeside).—Cuttings off the young shoots when about 3 inches long do best; or, what is almost as good, laying a few shoots down on the ground, pegging them there, and half covering them, will insure a number of plants, each joint generally rooting, and also sending up a leader.

PASSION-FLOWERS IN A GLAZED PORCH (Idem).—These are planted on a bed with pots of plants standing on them. There is no difficulty whatever in making strong-growing Passion-Flowers grow in your bed, which is 5 feet long by 1 foot wide, provided, in the first instance, that well-rooted plants, which have been in pots, be first planted there. In planting do not break the ball too much. It would be advisable to plant only the hardy robust varieties, as *Passiflora racemosa* and *coriacea*, &c., omitting *P. princeps*, *quadrangularis*, &c., as likely to suffer from the water they may receive from the potted plants standing over them. Let the border be well drained, and we have no doubt but you will be successful in presenting a good show with the aid of *Geraniums*, &c., standing over it in summer, and evergreens in winter.

LIFTING AND CUTTING-DOWN RHODODENDRONS (An Old Subscriber).—If your plants were only recently planted, they cannot want either pruning or moving yet. Generally speaking, Rhododendrons, however vigorous, flower well in favourable seasons, and rarely require cutting or pruning until they become very old and leggy. In that case they may be cut down in March or before, and in doing so it is advisable to leave a little foliage somewhere if possible; but they will grow without. Every season is not favourable to an abundant production of this and other kinds of bloom, and some of the hybrid varieties are more shy than others in flowering. Unless other reasons, as thinning or altering the position, render it necessary, merely transplanting them cannot do much good.

OLD CENTAUREA CANDIDISSIMA DYING OFF (An Old Subscriber).—Like old *Geraniums*, *Cineraria maritima*, &c., some of the old plants taken up out of the flower-beds in autumn do occasionally die, but we never knew them to be more likely to do so than other plants. Some plants we had sent us in December, and which had come 200 miles, or more, about six weeks before that time, and were then shaken out of the pot and subejected to another journey, have grown away tolerably well. Cuttings taken from these, as well as some other old plants that have been in heat all winter, promise to give us a good supply. Ordinary garden soil seems to suit it very well. In too rich soil we expect it will be liable to become more coarse and green-looking. The ensuing season will doubtless find it very much used everywhere.

FUMIGATING WITH TOBACCO (Anna, Norfolk).—The simplest and cheapest way we know of is to place a little sand or mould in the bottom of a flower-pot, to put about 1 inch of common candle into the sand, and then to crumple a few yards of small wire into a lump open enough for the flame of the candle to burn the tobacco that lies over it, and yet not so open as to allow the tobacco to fall between and put out the light. Sometimes we have split up a few bits of deal into pieces like matches and laid this on the wire, putting the tobacco at top. We use this homely contrivance in frames as well as in houses, as it is capable of enlargement or diminution at pleasure. The only thing the amateur has to guard against is not to let anything have the smoke too strong until he sees the effect. Better repeat the dose than overdo it.

CAPE BULB NOT FLOWERING (A Subscriber).—We have known more than one party disappointed in large imported bulbs not flowering, which is only to be attributed to the usual period of rest which all bulbs have being much protracted, and the lack of that bright unclouded sunshine they receive on their native hills. Cape bulbs are subjected to heavy and frequent rains at one period, when they grow profusely, and flower when dry sunny weather sets in, the bulb afterwards ripening and preparing the future flower-spike in embryo. In your case it is most likely the ripening and perfecting process was not completed when the bulb was taken up, and it will require a good growth here to accomplish this. Give it the advantage of a sunny stove until it ripens, after which let it rest the proper time, and it will flower. If it has not been subjected to frost, the mere fact of covering it or not with ashes or moss has little effect on it, the condition above ruling its welfare.

CINERARIA LEAVES INJURED (Amateur, Curragh Camp).—The leaf sent had more the appearance of having suffered from frost than from insects, a broad fringe all around being brown and withered. *Cinerarias* are easily injured by frost. If, however, insects do attack them, which may be the cause as well as frost, fumigate as directed in the case of another correspondent. The flower stem and buds, as well as the leaves, are liable to fall a prey to insects which are best destroyed by gentle and timely fumigations. We may also say that an overdose of tobacco will injure the foliage much in the same manner as that now sent, and it is quite possible your plants may have suffered from that cause.

FRUIT-TREE BUDS DEFORMED (Mrs. W.).—There must be some local cause for the fruit-tree buds becoming so shrivelled and deformed as the one sent to us. Has any pernicious factory smoke found its way to your trees, or is there an escape of gas at the roots, or has poisonous matter of any kind come in contact with the ground? Without knowing more of the condition of the tree, we can have no idea what is the matter with the buds. There does not seem any insect, as American blight or scaly coccus, to account for the disease, and mildew rarely attacks trees of the kind sent. We advise you to look to the condition of neighbouring trees, and if the same as your own, explain to us the features of the locality, and we shall then probably be able to state the cause. The remedy may, perhaps, be out of our power.

RHODODENDRONS DISEASED (Mrs. D., Westmeath).—We think they are suffering from a superabundance of moisture either at the root or in the climate, or from both united. A thorough draining will remedy the evil of too much stagnant water at the root, and possibly drier seasons may be in store for you than the last two or three years have proved. We had a similar case of disease to yours. Some Rhododendrons were planted round the edges of a pond which was low of water in 1857, 1858, and 1859, and they did pretty well; but the rains of 1860 subsequently raised the water level a foot or more, and thereby soddened the ground the Rhododendrons were growing in, and they have gone off the same way as yours, many of them being quite dead. Are your plants by the side of standing water? If so, we fear the evil is incurable, unless they are sufficiently above it to be moderately dry. Many other shrubs suffer more than Rhododendrons from a superfluity of water. If, therefore, draining be practicable, adopt it as soon as possible.

NAMES OF PLANTS, (*P. C.*).—*Rhododendron dauricum*. (*S. D. Goff*).—*Staphylea pinnata*.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

JUDGING POULTRY.

To adopt the opinions of our last week's correspondent would be simply to make a poultry revolution. Dorkings without five claws, Aylesbury Ducks with yellow bills! Why, shade of Sydney Smith, "Looking-in on railways would be nothing to it!"

Imagine a Dorking class; comb, colour, and claw, unimportant. Fowls to be judged according to their aptitude for fattening, and their market properties. What a scene when the public was admitted, if the judges had not taken the precaution to "skedaddle." Imagine the poor tired creature, "chopped" as he was making for the door, and brought back to be asked why he did not give the prize to 127, and civilly answering that there was a tinge of yellow on the leg; an absence of tail and fifth claw; an unquestionable leaning to fluff; all of which led him to think there was Cochin blood in it. To the question why he gave it to 91, he said their shape, symmetry, claws, indeed everything, bespoke their purity. Stuff and nonsense, his fowls had bred all through the year, he had had chickens at market every month. His were the largest, they fattened best, while 91 were purely fancy fowls. The old-fashioned nonsense about white legs, five claws, and all those fanciful distinctions were exploded.

This is not so much overdrawn as may be thought. If classes are not judged for points, what are they to be judged for, or by? If the classes are dissected, how many will there be left after those who exhibit for points are deducted from the number?

Shows are over for the season, there is a lull, and opportunely a Society is just formed which has for its object to compile points by which all classes *shall* be judged. The extremes meet. On one point alone they seem agreed—the present style of judging is unsatisfactory. It is amusing to hear people complain they do not know what to breed or exhibit, decisions vary so. Mr. Archer knew what to breed in Silver Hamburgs; Mr. Rake, in Spanish; Capt. Hornby, Lady Holmesdale, and Mr. Wakefield, in Dorkings; Mr. Moss, in Game; Mrs. Pettat, and Mr. Adkins, in Polands; Mr. H. D. Bayly, in Bantams; Mr. Fowler, in Ducks; Mr. Manfield, in Geese. All these were, and some are, uniformly successful. We predict failure for both extremes, and our belief is that rules are simply impossible. The man who cannot judge without, cannot judge with them; and no man can ever fill the office properly who has not either had the experience of many years, or the natural love for symmetry and feather, which amounts to a gift. We do not mean to say there are not mistakes made, and, in some cases, ignorance shown in judging; but, as a rule, complaints come from the unsuccessful. Very often the man who has finished the Red or White Lion, which is to be sign of the village public-house, looks at it with admiration, and when he compares himself with Landseer and Ansdell, is more prone to attribute the difference in their position to the blindness and injustice of the public, or the want of opportunity, than his own lack of talent; and so the exhibitor of three birds, two of which are excellent, and the third very inferior, or the possessor of that mediocrity which with content is the happiest station in life, looks from his commendation to the coveted first prize, or it may be "silver cup," and denounces the incapacity of judges, or asks what ANY ONE IS TO BREED.

Being somewhat looked upon by both sides as the poultry organ, we shall be glad to open our columns to them. The moment is well chosen, and good must be the result.

The supply of table poultry throughout England is notoriously deficient; the price is remunerative. Anything, therefore, that will remedy such a state of things will be a double good.

A BRAHMA POOTRA'S REMONSTRANCE.

IN common with my feathered friends I am much interested in the forthcoming Worcester Poultry Show, and on looking over the prize list I see that the Committee offer a deliberate insult to the kind to which I belong—viz., Brahma Pootras. Now, sir, Mr. Baily, no mean judge, says we are the hardest birds in England, and the best winter-layers; and at Mr. Stevens' sales we fetch higher prices than any other birds. What do you

think of the Worcester sages giving Crève Cœurs a class to themselves, and leaving Brahmas to compete in considerable numbers—for we are a large family—with a lot of French abominations with crackjaw names and few admirers?

Why, sir, both our varieties deserve a class—the dark birds, and the beautiful white ones with pencilled hackles.

"Wise men came from the east;" and if Worcester folk are fair samples of west countrymen, we must not expect much wisdom from the west.—BRAHMA POOTRA.

P.S.—My friend the White Dorking begs me to say that he is omitted also.

DURATION OF WORCESTER POULTRY SHOW.

I HAVE just received the prize list of this Show, a most liberal list, and am only sorry to see the Show is to be open so long. The whole of the poultry have to be in the building by Saturday night, and the Show is to be open to the public from Monday to Friday night; in which case exhibitors will not get their birds back till the Saturday: thus the birds are penned-up in pen and hamper for eight days—quite enough to seriously injure chickens and much too long to confine the old birds.

I hope the Committee may be induced to limit the days of exhibition to three, or at the most four, and I feel confident what they lose at the door will be more than equalled by the entry fees.—W. G. C.

ULVERSTON POULTRY SHOW.

THE seventh annual Exhibition of Poultry was held on Wednesday and Thursday last in the Victoria Concert Hall, a room in every respect most admirably adapted for a display of the sort being seen to the best advantage. There is good and equal light, good ventilation, and the attention of the Committee to feeding and cleanliness was everything that could be desired by the owners of the many valuable pens in the Show. In numerical quantity the pens considerably exceeded last year, and their excellent quality will be easily understood from a glance at the prize and commended list. On previous years the Committee of management have been complimented from various quarters on returning the birds from the Show in good order. This year we feel confident a like praise will be due.

Mr. Angus Sutherland, of Burnley, officiated as Judge. We understand it is his first season in that capacity; and from the generally satisfactory manner in which he discharged his arduous duties, we expect to see his name frequently in next year's poultry returns.

Amongst the varieties of the Show we noticed two pens in particular. One contained three remarkably fine specimens in good feather, and three-parts grown, of those shy wild Ducks the Shelldrake. Another contained a fine, large, full-grown hybrid between a Black Game hen and the Wild Pheasant.

In Class 1, Mr. Cannan, of Bradford, defeated the well-known Black Spanish of Mr. Teebay, and five others.

In *Dorkings*, Capt. Hornby easily defeated all competitors. Mr. W. Hill was second. In Black-breasted and other Red Game, Mr. Fletcher's birds, under the fostering care of Mr. Gilliver, secured first prize; Mr. T. Robinson pressing hard with a good pen. In Class 4, Duckwings and other Greys and Blues, Mr. Fletcher was again victorious with a capital Grey cock and two excellent hens; Mr. Joseph Hindson second. In Class 5, Any other variety of Game, Mr. Fletcher won with a splendid pen of Piles, about the best pen ever exhibited. The cock has won eighteen times without any defeat, and placed to the credit of his owner £64 in prizes. Mr. West had a capital pen of Piles for second. *Cochin-Chinas*, in Class 6, were a first-rate collection. After devoting particular attention, the card was up for Mr. Cannan; Mr. F. M. Hendle second. In Class 7, Golden-pencilled *Hamburgs*, Mr. Robinson, of Ulverston, was first with a beautiful pen, which had previously gained the cup at Kendal. Mr. Cannan was first in both Golden and Silver-spangled *Hamburgs*. In Class 11, *Polands*, Mr. Beldon was first and second. In Class 12, Any other distinct or cross breed, Mr. Lingard's Black *Hamburgs* bore away the prize in a good class of eleven competitors, including Mr. Teebay's pen of splendid *Brahmas*. In *Game Bantams*, Mr. Munn's beautiful pen defied all opposition, although seventeen others contended. A nice pen of Mr. Bayley's was second. In *Bantams*, Any other variety, Mr. Cannan was again in the ascendant, defeating Mr. Dixon and seven others.

In *Ducks*, Mr. Fowler was winner in the Aylesbury class, and Mr. T. Robinson in Rouens. A pen of Grey Call Ducks belonging to Mr. J. Dixon, was first in Ducks of Any other variety, and Mr. Earle's East Indian second.

In the *Game Cock* class, Mr. Fletcher was first with a noble-looking Black Red, winner of many prizes, and Mr. Boulton second with a Brown Red, which was third at Birmingham, first at Manchester, and third at Whitehaven. Mr. Fletcher was third, and Mr. Redhead fourth with a beautiful blood-like Black Red. In *Game Chickens* and two pullets, Mr. Grimshaw was first with a pen of capital birds; Mr. Fletcher second, and Mr. E. Aykroyd third.

In *Game Bantam Cocks* Mr. Bayley exhibited one of the most beautiful birds ever seen. Mr. C. B. Kennedy, of Ulverston, was second, and Mr. Fletcher third.

WHITEHAVEN CANARY, POULTRY, AND PIGEON SHOW.

FOR five years past a Poultry Exhibition has annually taken place at Whitehaven, under the management of a small but enthusiastic committee of local poultry-fanciers. At the outset the Exhibition was indeed a small one; but the originators, in no way foiled by the paucity of the entries, perseveringly pursued the same honourable and straightforward conduct that still marks all their proceedings, until their Meeting well deserves mention as one of the best to be visited in any of the northern counties. Even a cursory inspection of the printed catalogue will convince any one that the competition now embraces a very considerable proportion of our most noted breeders; and we may, for the information of our readers, preface our few observations on this year's Show by stating the entries were more than a hundred pens in advance of those of the year 1862.

We offer the Committee our hearty congratulations on their success, and hope that each succeeding year may still add notoriety to their well-merited position among our local exhibitions. The Refuge School, in which the Exhibition takes place, is exceedingly well situated for the accommodation of visitors, being actually in the public market-place, so that the Show necessarily becomes an annual treat not only to the actual residents of Whitehaven, but is generally so to the numbers who visit the town from many miles round for business purposes. The only drawback is, that some portions of the room are comparatively dark from want of a direct light into the pens; but this objection has been materially lessened by the application of temporary gaslights, while a little alteration in the disposition of the pens in future years will leave very little to be complained of on this score.

The first class was for Black-breasted and other Reds, *Game* fowls, and a capital competition ensued. Most unusually, the Black-breasted birds took all the premiums, and were shown in a tip-top condition most creditable to their respective owners. The Duckwings, though few in numbers, were very good; in fact, birds of this colour were more than generally good throughout the Whitehaven Show. In the *Game* class for Any other variety were shown a very good pen of the now-almost-extinct breed so well known in times past as Worcestershire Piles. In the days of the cock-pit they were notoriously the most indomitable of fighters, and the most lasting birds that could be placed on the turf, but perhaps not so quick fighters as some others, whilst their curiously-marked plumage gave but little hope to the inexperienced of their unvarying pluck; so much so that old cockfighters assert that not a single instance of cowardice could ever be pointed out in this almost-forgotten variety. A pen of uncommonly good White *Game* stood first, however, in this class, and Red Piles took second honours, the Worcestershire Piles having to remain content with a high commendation. The only class in which a falling-off appeared was the Black *Spanish*, and therefore we omit any further reference to them.

The whole class of *Dorkings* consisted of large and superior specimens, and it augurs well for the great improvement of late in White *Dorkings* to report that in such a competition a pen of this variety took second position against all comers.

In *Cochin* fowls, all colours competing, the Partridge birds were far in advance of the remainder, and were numerously exhibited; they thus, of course, cleared the prize list.

As a satire on the breed, we rather presume, a local competitor entered a very good pen of *Brahmas*. In this class they

remained unnoticed, though in the class for Any other variety of poultry they must have maintained an excellent position.

The *Hamburgs* were quite a befitting collection for the northern counties, where first-rate excellence is always anticipated. The hen in the first-prize pen of Golden-pencilled birds was undoubtedly one of the best ever yet exhibited. The Golden and Silver-spangled *Hamburgs* were far beyond mediocrity, but the Silver-pencilled were comparatively a failure.

The only *Polands* worthy of special note were the White-crested and the Golden-spangled.

The *Game Bantams* were, perhaps, one of the very best classes in the room, Duckwings, Black Reds, Brown Reds, Piles, and Birchen Greys being well shown; but it really was a misfortune for this truly pretty class—always, by-the-by, quite favourites with the public—to have to while away their confinement in one of the darkest positions in the show-room. A provision against this another year would certainly be an improvement. The Gold and Silver laced Bantams were also good. A decidedly good competition ensued in the Any other variety class for Bantams; so much so that thrice the number of prizes to be allotted could have been easily and deservedly distributed.

The Aylesbury *Ducks* fell short of the generally-accepted standard; but the Rouens made great amends for their shortcomings. Wild Ducks and Buenos Ayrean Ducks were shown in perfection.

We next come to the *Pigeon* classes, and never, perhaps, has a more meritorious collection, if limited to the same number of pens, been exhibited. The Carriers proved one of the strongest classes, the Dun birds taking the highest position, Blacks the second, whilst high commendation seemed on every hand called for. The Almonds were very good, and among the Baldheads were a pair of as perfect Reds as need be desired. The Trumpeters, particularly the White ones, and the Jacobins (in many varieties of colour) were so good that it was by no means a covetable task for any arbitrator to assign superiority. The Barbs, Turbits, and Owls were also of the highest character. In the class open to all other varieties of Pigeons were some extraordinary high-class Runts (Silver Duns), and some specially good Frillbacks. Altogether, the Pigeon classes were superior to any we have had the pleasure of inspecting for many months past.

As a fitting tailpiece to the Whitehaven Poultry Show came two Single *Game Cock* classes—the one for adults, the other for cockerels. To the latter, money prizes were the order of the day; to the old birds, a silver cup in addition. The competition in both classes was extreme, and representatives of every colour of *Game* fowls were competing. The winner of the silver cup was a magnificent Black-breasted Red belonging to Mr. C. W. Brierley, of Oakenrod Terrace, Rochdale, and which proved one of the most specially attractive objects on view. The covetous desires of on-lookers, however, were soon dissipated, on a reference to the catalogue, where his value was estimated by its fortunate owner at a cool £100, most probably to insure its safe return. Under this proviso, it was really amusing to witness how soon the ardour of anxious "claimants" evaporated. Many of the remaining birds were most excellent. In the Cockerel class, Mr. T. Robinson, of Poplar Grove, Ulverston, exhibited a Brown Red that will take a very great deal of beating before he can be surpassed if kept up to his present condition; for not only is he of faultless colour, but as perfect in the hand as could be wished for, and one of the hardest-feathered *Game* cockerels ever shown.

Before concluding we must make one observation as to the silver cup given to the best adult *Game* cock at the Whitehaven Show. It was really a good one and such as any winner might be proud of—a feature, we regret to say, by no means universal in the silver cups given to poultry of the present day. It was a honest representative of value; and if some few of our poultry committees will take down this gentle hint as a guide in their future distributions, we can confidently assure them it will add most materially to the popularity of their coming shows, for the present case stands out in pleasing contrast to the many instances that might be adduced of cups proving (when obtained), not worth one-fourth or even a sixth of their reputed value. The remedy is easy, and the line of conduct for the guidance of committees quite without dispute—viz., if silver cups are to be allotted, by all means let them be nearly approaching in value to the worth represented, or at least leave the winner the opportunity of receiving the money instead, under which arrangement no objection can reasonably ensue. It is not, in our opinion, a

legitimate source of revenue to any committee to limit the actual value of their silver cups to perchance but little, if any, more than a fourth of the sum stated, so that the fact stands out apparent, that the winner of the second prize has ultimately a decided advantage over his rival, by the personal purchase of a much-better-manufactured and more weighty cup with the proceeds of his second position on his return home, with, it may be also, a trifling overplus into the bargain. As such malarrangement absolutely stultifies the original intention of giving silver cups as first prizes at poultry shows, we again repeat, the Whitehaven Meeting has offered them a rule which is well worthy of their imitation on future occasions.

The part of the room appropriated to the exhibition of the Canaries and other singing birds, was well-stored with excellent specimens.

A list of the prizetakers appeared last week.

POINTS OF MALAYS.

IN your impression of the 24th ult., a correspondent, "Y. B. A. Z." in his "Dottings at Devizes" said, "Some Malays were there most conspicuous by their ugliness."

I am a Malay-breeder, and should have been glad if your correspondent had pointed out which were conspicuous, or whether all of them were not so. There are some persons who consider this class of fowls extremely ugly; I do not. I think as a class they are extremely beautiful; but after breeding them for twenty years, and having been successful at some shows, and unsuccessful at others, I have yet to learn the good points of a Malay, and what are its true characteristics.

I wish there were some settled point of eminence to which breeders could direct their attention. I never did, and I never shall, dispute the decision of judges; but I must say that I am puzzled to know what kind of birds to breed to insure success, for one judge decides to give a prize to one colour and form at one show, and another judge acts differently at another show, so that they appear to have no rule to go by, and "when doctors differ their patients suffer." Uniformity of character, therefore, seems to be required, and how is this to be arrived at? Perhaps you or your correspondent will kindly inform me through the medium of your Journal.—JOHN JAMES FOX, *Devizes*.

[We agree with you, we like Malays, and we have liked them for years—more than twenty. It is forty years since we first knew them. There are few judges of Malays in England. One of the best, if not the best, is Mr. Andrews, of Dorchester. We believe there has never been but one standard with that gentleman and those with whom he mostly acts. We will give our notion of what a Malay should be. The body should describe three bends or bows, one from the head to the shoulders, one from the shoulders to the rump, and the last from the rump to the end of the tail. A Malay should have a drooping tail. The comb should not be a pea comb, nor a lop comb, but a hard, rough-skinned one, flattened down on the head, and perfectly tight. The eyes should be bright and pearly. The throat bare, hackle very scanty; short, hard feathers on the breast dividing at the crop, which should be visible, naked, firm, and red. Scanty feather is a characteristic of the breed; the point of the wing at the side of the breast, and the higher joint of the same wing level with the back may both be bare. The wings should stand out from each side of the body plainly as if they were carved in hard wood. There is in a good and pure Malay no fluff, no plumage to hide shape, and, therefore, the body tapers to a point to the tail. The hip bones are plainly visible, and the strong, wide-apart legs, with round, hard thighs, and large but well-proportioned knees. They should be very hard in hand, and have little or no feather on the hinder parts of the body. There is no fixed colour for the legs or plumage.]

WARNING.

ALLOW me a few lines in your Journal to caution poultry and pigeon fanciers against lending money to a young man, who has been living on borrowed money and other nefarious means for some time back. He called upon me more than twelve months ago, but was evidently disappointed—he obtained nothing, but he has since revenged himself by making too free with my name in drawing money from others. His plan is to introduce him-

self as Mr. Shaw, of Stainland, where he finds I am not personally known to the parties, or as my brother if I am known; and thus by throwing people off their guard, succeeds in most instances in borrowing money under some frivolous pretext or other. He has in this way duped a great many fanciers out of sums varying from 5s. to 30s. each. I heard of him a few weeks ago borrowing money in my name in Manchester, and it is very probable he is the notorious Beewick Lodge correspondent.

If I remember rightly he is rather well built, and has reddish hair and whiskers. I shall be glad if this notice will be the means of stopping his supplies, and handing him over to the care of the police.—S. SHAW, *Stainland*.

SUPERPOSING IN STAFFORDSHIRE—SEASON IN RENFREWSHIRE.

THE following is in reply to the inquiry of "A NORTH-STAFFORDSHIRE BEE-KEEPER," in No. 99, page 144, as to his superposed hive. The division of a crown-board, with end openings only between two sections of a storified-hive, would, doubtless, to a certain extent, "affect their future welfare" by interrupting the queen's free progress through both, and thereby curtailing her production from what might otherwise be expected, were the entire combs as open to her perambulations as when there is the usual space between every bar. Then, although the stock ultimately attained an altitude of four or five instead of but "two storeys," such a height, rather than being a disadvantage, would give promise of weighty supers during a favourable season. As a general rule, the roomier the stock the longer is natural swarming protracted, although the swarm is all the larger when it comes.

Assuming from the description of your correspondent that the present upper portion of his superposed stock is but a cap, or small hive—in that case he might, the stock being strong, remove it filled as a super without materially retarding the swarming of the stock, should the summer be good; but as he seems desirous to increase his hives, perhaps the speediest mode to accomplish this would be, on the first appearance of drones, during the middle of a fine day, to attach the upper hive to an eke, and then invert the lower, beating up the queen, together with the bulk of the inmates, and remove it then—say a mile or so off for two or three weeks. The absent foragers, with those left in the lower hive, would in the interim raise a young queen.

The last year was quite as miserable a bee one in Renfrewshire as it could possibly be in Staffordshire. The season of 1860 was bad, 1861 worse, and 1862 the worst the present writer has any recollection of since he knew anything of bees and bee-keeping. Many he remembers as enthusiastic bee-keepers since his boyhood fed their stocks at the close of 1860, hopeful for 1861, fed again that season; but in disgust let them take their chance in 1862, trusting solely to the tolerably good month of August at the heather, and this spring finds them totally bankrupt in the bee way.

My own apiary at the beginning of last year consisted of six stocks—three weak, and three strong; and, anticipating a good season after two such poor ones, besides the arrival of a Ligurian stock from Devonshire, I kept my favourites in tolerable condition as the summer advanced by repeated drafts on the crushed-sugar cask, but unfortunately neither the good season nor the Ligurians arrived. I then turned my attention to equalise my stock; my three strong ones were by this time strong indeed, built out, quite at suffocating-point, but they thought better of it than swarm, and were consequently nearly idle.

To remedy this I began operations first on the strongest, in a Stewarton hive and eke wrought on the adapter plan, which I will now describe as No. 1, beat out the inmates into a similar hive and eke; and, with the assistance of a little feeding now and then, they, by the end of the season, had filled their new hive with comb. Into their vacated hive I placed an unusually-prolific queen, the monarch of another Stewarton-adapter which had met with a misfortune and was now rated as one of my weak ones. Her subjects speedily hatched-out the large quantity of maturing brood this hive contained, and were so reinforced in consequence, that in the end No. 2 was, if anything, superior to No. 1. The combs left by No. 2 I set in frames, and I placed them, alternately with blank ones, in an empty box under No. 3, a strong stock in a frame-hive: this gave them plenty of fresh air and employment in completing the frames in their lower hive.

No. 4 was a very weak colony in a straw hive with an agile dark queen, but with by far too small a population ever to prosper in so large a domicile. I therefore picked out four frames well stored with brood and food borrowed from No. 5, and placed them in a frame-hive with temporary contracted moveable ends, into which I transferred her and her attendants. So delighted were they with the change, that from being a peculiarly inert helpless squad they were transformed into the pluckiest little colony in the lot, improving to the utmost every favourable blink. The combs of their old straw hive were cut up to partially furnish a lower box for No. 5, which, by the way, was a particularly good colony, shifted from a nine-inch-deep bar-hive into a frame one. To the beautifully-loaded tops of their bars we were indebted for the only remembrance of a honey-harvest obtained. No. 6 was a weak colony in a frame-hive, reinvigorated by a contribution of three heavy frames levied from the strong stocks.

After a large and final draft on the cask, I set my half-dozen stocks fast on their ekes for the winter, thankful that the disastrous season of 1862 had passed, leaving my industrious little friends, although not an augmented, still not a diminished, band, and in better trim to begin the campaign of 1863 than 1862 had found them. That campaign opened I may say on the 31st of January, such a day as your esteemed correspondent, "A DEVONSHIRE BEE-KEEPER" described the 29th to have been with him, when I had the pleasure of seeing the first indications of pollen-carrying, only two days later than with his beautiful Italians in salubrious Devonshire. They have lately embraced every favourable moment in this unusually mild spring to rifle the aconites and crocuses now in bloom. This, however, will have no effect in tempting their master to deviate from his usual course of increasing the temperature one whit till March has fairly lost her "adder head," and displays the departing azure brilliancy of her "peacock's tail" when, by withdrawing the ventilating ekes, and administering small doses of food, each stock will be put upon its mettle.—A RENFREWSHIRE BEE-KEEPER.

DRONES IN MARCH.

OUT of a Ligurian hive to-day (3rd March), which is very warm, I saw two drones come. The hive was populous last year, and was the only one that swarmed (it swarmed twice). But misfortune overtook it on the moors, for it came back populous but devoid of honey. I have fed it by bottle all the winter, and this day, the first warm one (out of the sun), they have taken their first spring flight. I observe that they have pulled out many immature bees, as far as I can see, not drones, which proves that breeding has been going on, and that there is the possibility of a queen existing. Whether it is only the comparatively common occurrence of a hive deprived of its queen, and of working bees breeding, I know not; but the existence of drones on the 3rd of March is worthy of note.—A NORTHERN BEE-KEEPER.

[Setting aside the possibility of a drone-breeding queen or of fertile workers as anticipated by "A NORTHERN BEE-KEEPER," either of which circumstances if they exist, will probably soon make themselves sufficiently evident by the undue development of the male element in the hive; there is yet another contingency which will account for the occasional appearance of a few drones in March. This is the irregular deposit of isolated drone eggs amongst those of workers, which sometimes occurs, and of which I saw an instance only a few days ago in one of my own stocks. In the middle of a patch of sealed worker-brood projected the unmistakable hemispherical cover of a drone larva which has probably arrived at maturity, and may even have taken its first flight before these pages are printed.—A DEVONSHIRE BEE-KEEPER.]

MEETING OF GERMAN BEE-KEEPERS AT POTSDAM.

THE bee-keepers of Germany held their tenth annual meeting at Potsdam, on the 17th, 18th, and 19th of September last. Here were met the most distinguished "bee-fathers" of Vaterland, the illustrious Dzierzon and his nephew, who is stated to be a worthy follower in his uncle's footsteps, Baron von Berlepsch, Count Stosch, Pastor Kleine, and a host of others more or less distinguished, to the number of from 500 to 600.

The following is an epitome of the subjects brought under discussion.

I. *What are the results of experience with regard to the advantages and disadvantages of the Italian bee?*

Herr Radlow who was the originator of this inquiry, stated that he had himself but little experience with the Italians, and he therefore requested Pastor Dzierzon to enlighten them on the subject.

Pfarrer Dzierzon in reply said, "When ten years ago I received the first Italian stock, multifarious opinions were promulgated concerning them. Some said the Italian bees were nothing but German bees in a coloured dress, they were merely a climatic variety, and in our climate would soon degenerate into the common grey or black bee. This opinion has not, however, been confirmed. The Italian bee is a distinct species, which is not only of a different colour, but has also other great peculiarities which have since come to light, especially during the past year. The Italian bee is decidedly more diligent and richer in honey. When I examined my hives in the beginning of last August, what a striking difference was there to be seen between the Italian and the black bee! Unfavourable as this season has been, the Italians had generally much more honey, but on the average fewer bees. The Italians begin breeding earlier and cease earlier than the black bees. Being more diligent and intrusive, they wear themselves out more rapidly, and therefore a greater mortality must be the result. Towards autumn, however, it must at all events be agreeable to bee-keepers to find more honey than bees, whilst as greater diligence must naturally produce a greater result, they are decidedly better honey-gatherers. That the Italian bee is less inclined to sting is undisputed; and this is a great advantage, since the bee-sting is very formidable to some, whilst in most a degree of swelling is produced which is very disagreeable to clergymen, teachers, and others who have to appear in public. Then the Italian bee is more watchful, and will not submit to be robbed by others like the common species. Even the weakest stock, if it has a queen, will repel courageously the most violent attacks from strangers—at least it is so with me; for though I am frequently obliged to operate in the robbing season, not one Italian stock has been plundered. My conviction is that these advantages are of such importance, that it is well worth while to bestow both care and attention on the introduction and multiplication of the Italian race" (cheers).

Herr Gotze declared the Italians had many advantages, but no disadvantages. Passing through a teazel field in full bloom after seven o'clock in the evening he was surprised to find a number of bees still working zealously. A close examination proved them to be all Italians, not a single German bee could be found among them. The flight continued until eight o'clock.

Pastor Kleine declared the superiority of the Italian species to be beyond a doubt. It had also been of great value in deciding debatable points, such as the intercourse between the sexes taking place outside the hive, and but once during the life of a queen—the doctrine of parthenogenesis, which has been of so great importance in physiology—the turning-out of fertile workers being an indispensable element in every normal hive—the discovery of the mode of life and duties of young bees—and the longevity of workers. He also considered that bee-keeping in order to prosper should be a favourite occupation. Every one who has introduced Italian bees into his apiary must confess that his love for bees has been increased, and that by their means he has become rapidly initiated into the mysteries of bee life (applause).

Herr Harmuth declared his preference for the hybrid race, stating that the true Italian bee neglects the heath.

Pastor Kleine, on the contrary, averred that the Italians seemed to riot in the blossoms of the Lüneburg heath.

II. *How may water-dearth* be discovered, what are its consequences, and how can it best be prevented?*

Count Stosch recommended the honey-room being on the same level as the brood-room, avoiding the use of too thick as well as stuffed double walls, but giving the bees water in a sponge.

Pastor Dzierzon agreed with the former speaker, recommending also a supply of water outside the hives in vessels covered with moss, and keeping the floor-boards cool in order to promote condensation upon them.—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

* Water-dearth is an evil which is, so far as we are aware, unknown in England, and appears to owe its existence to the extreme dryness of the atmosphere in Germany.

SALT NOT BENEFICIAL TO PIGS.

I HAVE had to do with pigs more or less for fully forty years, and for the last twenty-five years have bred and fed not a few for my own consumption, and to sell to private families. I have read everything I could find about the management of pigs, and tried many sorts of food and different ways of feeding. Amongst others I have tried salt, although I had seen its injurious effects as I have stated at page 753, in the volume just concluded.

It will be remembered, that in Vol. XXVI., page 188, there is a paper read by Mr. Stearn, of Brandeston, Suffolk, on the management, breeding, and feeding of pigs, and to my mind he is the best authority on the subject I am acquainted with. He sprinkles salt on the food for his young pigs, and it may seem in the opinion of some to be rather daring to condemn salt in the face of such an authority: yet I do, and I will endeavour to make it appear why in as clear a way as I can.

In the first place, I am quite aware that to salt a pig's food as a man would salt his own porridge will do a pig no harm when the pig has become used to it; but the question is, Does it do him any good? I say it does not, so far as my experience goes; and in the next place I have had plenty of proof on several occasions of the injurious effects that brine has had on pigs when thrown in the swill-tub, even when there has been no saltpetre in it.

As regards boiled potatoes salted down in large quantities to be used as wanted, which was, I suspect, what Mr. Pearson did, and which was the case with the potatoes and pigs referred to at page 753, I will show from experience that the same quantity of salt given to a pig—that is, sprinkled over his food at the time of feeding and mixed up with it—which would do him neither good nor harm then, would do him a serious injury if mixed in the same proportions and put two or three hogsheads of it together, and allowed to stand a month or two before being used.

In 1855 I had a quantity of bad potatoes; and knowing if I did not boil them all up at once I should lose a great bulk of food, knowing also that salt does not make pigs ill if given as above stated, and thinking that others had been too bountiful in the use of it, I determined to try an experiment for myself, but at the same time had no faith whatever in the good effects of salt.

I have a tub that measures 3 feet 9 inches at bottom, 4 feet 9 inches at top, and 3 feet deep; and as it was the first week in August and I did not want to begin feeding my pigs till the first week in October, I determined to fill the tub with potatoes, and salt them down as I term it. First, I put potatoes in when boiled, and smashed them till they were 1 foot up the tub and quite solid and level on the surface. I then sprinkled salt all over the surface. I next smashed in another tub, and filled into the large one 1 foot more, with salt as before; then another layer 1 foot thick, likewise with salt, and that filled the tub. I put no more salt, according to the quantity of potatoes, than I should have put on potatoes that I was going to eat myself, and, consequently, no more than might have been put in a pig's meal at the time of feeding, and given without any ill effects.

When I had used up all the offal I had in the shape of brewers' grains and refuse from the kitchen and garden, the salted potatoes had then stood two months, and my pigs were about 11 score a-piece and half fat. I then began giving those salted potatoes mixed with beanmeal. I dug the potatoes out of the tub with a spade, into a bucket, then put to them the beanmeal and as much water as made the whole about the consistency that a bricklayer would use his mortar. This was given to the pigs, and all went on well enough to outward appearance; still I thought they did not eat their food with that relish they used to do. Neither could I see that they went on any better than my pigs used to do with the same food without salt; but nothing happened till they had eaten about halfway down the tub, then came the grand secret.

I fed as usual at night. I put the food over the wall into the trough; it was dusk, and as I was not aware of anything amiss I did not go again till breakfast-time next morning, and then to see my pigs in the same plight that I had seen other folks' from the same cause! They had not eaten all their supper, and there they were scouring all up the walls and about the sty, opening their mouths as wide as they could, then champing their jaws together, then gaping again, then champing, which told me they were sick at stomach. I knew at once what was the cause, and the effect was plain enough, and all I had to do was to remedy the evil in the quickest and best way I could.

As soon as I had time I examined the potatoes that were left in the tub, and the place I had taken out their allowance was

filled up with stuff in a liquid state. I tasted it, likewise put some potatoes in my mouth and chewed them. Both were alike of a nasty brackish taste, a good deal like the mineral water I have tasted either at Brighton or Malvern, but forget which, or like water that a lot of rusty old iron had lain in for some time. It did not taste as salted porridge would, and it is fresh in my memory to this moment. I dug down to the bottom of the tub, turned it over, and found the potatoes the same throughout. It is natural to suppose if there had been no salt used that the potatoes at the bottom of the tub would have been more moist than at the top, after standing so long; and my humble opinion is, that the salt put on the top when the tub was full, gradually settled down with the moisture that the potatoes contained, and took the second lot of salt with it about 6 inches lower than where it was put, and that, with the next lot of salt and the moisture from the potatoes, had formed brine enough to well saturate the potatoes for about 18 inches from the bottom of the tub. I am satisfied that brine either from animal or vegetable substances, is injurious, if not poison, to pigs, and it is probable that if my pigs had been strong stores just brought in from where they had not been half fed, and eaten eagerly, as they would have done, to their fill, it would have killed them outright. I think it will be seen that salt acts quite differently when used in different ways, and why, I will leave wiser heads than mine to determine.

Now for Mr. Pearson's question, why I think salt is not good for a pig, if it does him no particular harm; and the reason is, because it is not in the nature of a pig to eat or lick salt with his own free will like sheep or cattle, whenever they come in contact with it. Between the years 1845 and 1855 I lived for five years near some saltworks in Worcestershire, and on the premises there had been some new buildings put up, and at certain times of the year the face of the bricks for 2 feet or so from the ground would be incrustated all over and quite white with salt. Whenever the sheep or cattle came into the field adjoining these walls they would at once begin licking this salt off, and although we had in general from fifteen to fifty pigs that were at liberty to do the same, I never saw one do it. Again: The canal came through our fields, and at the locks the salt-boats would often stop and put out lots of salt to alter the arrangement of their cargo, and to stow away the fresh meat for their voyage; consequently, there were often lots of salt strewn on the large stones that were round the locks, and I have seen the sheep and cattle go and lick all the salt up as clean as if it had been washed off; but the pigs had the run of the same fields, and I have watched their proceedings, and they would walk over these stones without taking the slightest notice of the salt. I should have stated, that the pigs would rub themselves against the above-mentioned wall without notice of the salt, and I venture to say that pigs, dogs, poultry, and ferrets will thrive without salt.—WORCESTER.

OUR LETTER BOX.

BLACK BANTAMS' COMBS (J. L.).—There is no fixed comb for a Black Bantam. It may be double, or single, or cupped. The latter would be no proof of impurity, because wherever there are single there will sometimes be cupped combs. It is a very common thing for the Sebrights to show all sorts of combs. We have seen them so curious as to be ridiculous, and look more like a thing made in sport than a production of Nature. A cupped-comb is not desirable, nor would the possessor of it be likely to be a prize-taker.

BRAHMA POOTRAS.—We are informed that letters directed to Mr. Hargreaves, Bacup, Lancashire, have been returned from the dead-letter office.

COVERING BEE-HIVES (Mr. J. Penn).—Covering them with stable litter, as recommended by Mr. Payne in "Bee-keeping for the Many," is an experiment which we have never tried, but we should say, Keep them covered until the nights cease to be cold, or until the bees become sufficiently numerous to set the cold at defiance.

VENTILATION.—WINTERING BEES IN GLASS HIVES (B. W.).—If you will peruse my communication in pages 159 and 160, I think you will find it sufficiently explicit. My mode of ventilation is, however, inapplicable to bar-and-slide hives. Perhaps the best plan with these hives would be to draw out one or two slides on each side, and cover the apertures with perforated zinc. I never attempt to winter bees in glass hives, but always shift them in the autumn into wooden boxes. The late Dr. Bevan informed me that he once succeeded in keeping bees alive through the winter in a unicomb-hive, which was placed in his drawing-room, and well protected by woollen wrappers.—A DEVONSHIRE BEE-KEEPER.

WORK ON BEES (An Old-fashioned Bee-keeper).—If you will send to our office five postage stamps, with your direction, and ordering "Bee-keeping," you will have it free by post, and it contains what you require.

LOSS OF HAIR ON DOGS (L. C.).—Your hairless two-year-old Toy Terrier, descended from a blue tan grand sire similarly bare, probably never will have any hair. The ointment we mentioned last week would not injure your dog, just enough to grease the surface being used at a time; but we can hold out no hope of its producing a crop of hair.

METEOROLOGY OF THE WEEK.—At Chiswick, from observations during the last thirty-six years, the average highest and lowest temperatures of these days are 50.9° and 33.9° respectively. The greatest heat, 67°, occurred on the 19th and 20th, in 1836; and the lowest cold, 17°, on the 20th, in 1845. During the period 156 days were fine, and on 96 rain fell.

THE PROGRESS OF FLOWER-GARDENING.

in nearly every parish around cities and towns, such flowers must have been in high repute. It appears that they were not only cultivated for exhibition, but also for planting in the beds and borders of the flower garden.

I can well recollect the fine display that I have seen many years ago, when the beds were filled with Crocuses, Anemones, Hepaticas, Auriculas, Hyacinths, Tulips, Cowslips, Ranunculuses, Narcissi, Ixias, Gladioli, Polyanthes, Carnations, Pinks, Lilies, Double Rockets, &c. Herbaceous plants were also of some service to give variety to the beds and borders, and when annuals were introduced, more especially the sorts sent home by Douglas, they combined to produce a pleasing but transitory effect.

Abercrombie, Nicol, and other practical gardeners of their time, seem by their writings to have had no distinct ideas on the subject of arranging flowers in flower gardens. However, Nicol in his "Gardeners' Kalendar," published in 1810, gives the following instructions on the formation of gardens—"A variety of forms may be indulged in without incurring censure, provided the figures be graceful, and not in any one place too complicated. An oval is a figure that generally pleases, on account of the continuity of its outlines. Next, if extensive, a circle. Next, perhaps, a segment in form of a half moon, or the larger segment of an oval. But hearts, diamonds, triangles, or squares, if small, seldom please. A simple parallelogram, divided into beds running lengthwise, or the larger segment of an oval, with beds running parallel to its outer margin, will also please."

The following observations made by a lady, authoress of the "Florists' Manual," published in 1806, are the first indications that I have found worthy of particular notice, as they attest, to my apprehension, the first approach to a correct taste in the arrangement of flowers. "In the formation of that assemblage of flowers which may be distinguished by the term of the mingled flower garden, it is essential that the separate parts should, in

No. 103.—VOL. IV., NEW SERIES.

their appearance, constitute a whole, and this appearance is not incompatible with any form into which the ground may be thrown, if attention be given to the manner of planting. In some gardens this appearance of a whole is entirely destroyed by the injudicious taste of setting apart distinct borders for Pinks, Hepaticas, Primulas, or any other favourite kinds of flowers; also for different species of bulbs, as Anemones, Ranunculuses, Hyacinths, &c., these distinct borders, although beautiful in themselves, break the whole, that should always be presented to the eye by the mingled flower garden, as single beds containing one species only form a blank before that species produces its flowers, and a mass of decaying leaves when the glow of their petals is no more. The reverse of this mode of planting is essential to the perfection of the mingled flower garden, in each border of which there should be at least two of every species, but the precise number must be regulated by the force of colour displayed by the plants, and the size and relative positions of the borders. It will be only necessary to observe, that to whatever view the garden presents itself, the eye should not be checked by the failure in any part of it, of the prevalent colours of the season."

I think Mr. Hogg, who was master of an academy at Paddington, Middlesex, was the first writer to give us some ideas on the arrangement of colours. In his "Treatise on Flowers," published in 1812, he says—"We are apt to ridicule the Dutchman, as well as the imitators of him here at home, who divide their gardens into small beds or compartments, planting each with separate and distinct flowers. We ridicule the plan because it exhibits too great a sameness and formality, like unto the nosegay that is composed of one sort of flowers only; however sweet and beautiful they may be, they lose the power to please, because they want variety. It must, undoubtedly, be acknowledged that a parterre, no matter in what form, whether circular or square, elliptical or oblong, when all the shrubs, plants, and flowers in it, like the flowers of a tastefully arranged bouquet, are variously disposed in neat and regulated order, according to their height and colour, is a delightful spectacle, and worthy of general imitation. Yet, still, in some particular cases, I am disposed to copy the Dutchman, and I would have my bed of Hyacinths distinct, my Tulips distinct, my Anemones, my Ranunculuses, my Pinks, my Carnations, distinct, and even my beds of Hollyhocks, double blue Violets, and dwarf Larkspurs, distinct, to say nothing of hedgerows of different sorts of Roses. Independent of the less trouble you have in cultivating them when kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them. Mrs. Siddons, the celebrated tragic actress, is a great admirer of this mode of planting, and fond of contemplating their beauty in masses. She adopted this style of gardening at her late residence on the Harrow Road. Her favourite flower was the Viola amena, the common purple Heartsease, and this she set with unsparing profusion all around her garden."

No. 755.—VOL. XXIX., OLD SERIES.

I also think that the taste displayed by Mrs. Siddons in the arrangement of her evergreens, to give a cheerful appearance to her suburban villa during the winter months, is worthy of notice. It was planted with Box trees, Fir, Privet, Phillyrea, *Arbor Vitæ*, Holly, Cypress, the Red Cedar, Laurel, Irish Ivy, Bay trees, *Laurustinus*, *Arbutus*, Spurge Laurel, &c. After the display of flowers was over, it was, no doubt, viewed with a degree of satisfaction, as giving rise to a pleasing association of ideas, in beholding their green verdure at a time when deciduous trees were stripped bare.

Mr. Loudon, in his descriptive notice of the gardens of the Misses Garnier, at Wickham, near Fareham, in the "Gardener's Magazine" of May, 1834, tells us that the bold masses of brilliant-coloured flowers and the succession of masses of flowers, with their intervening glades of turf, extending to a considerable distance till the colours were almost lost in the boundary plantation, produced a landscape of the most brilliant kind. When we look closely into the ground-plan of that garden, and examine the details, we find that beauty in masses is the predominant feature, combined with a smaller portion of the mixed system. There are beds of herbaceous plants distinct; Perpetual Roses distinct; Roses edged with Pansies; *Potentillas* and *Calceolarias* edged with *Viola cornuta*; *Hollyhocks* edged with *China Roses*; beds of *Pinks*, *Pelargoniums*, and *Verbena chamædrifolia*; a collection of *Phloxes*; *Fuchsia carnea* edged with *Lobelia triguetra*; *Lupines*, *Hydrangeas*, *Petunias*, *Mimulus*, and *Pæonies* distinct. We also find that there were only *Verbenas chamædrifolia*, *pulchella*, *Lamberti*, *Aubletii*, and *venosa*, and *Geraniums sanguineum*, *Lancastriense*, *sibiricum*, and *Wallichianum*, which are very old and inconspicuous sorts when compared with the variety and brilliancy of the sorts now in general cultivation. We are directed by Mr. Loudon to the Rev. Thomas Garnier, at Bishopstoke; to Mrs. Corrie, near Birmingham; to Mrs. Robert Phillips, near Cheadle; to Lady Broughton, near Chester; and to Mrs. Starkey, at Bowness, as the most distinguished places where the beds were most judiciously planted, and the order and keeping of the whole were of the very highest and most refined description.

Hay, "On Colours," tells us that all know that the arrangement of notes in a melody is regulated by fixed laws, proved also by the natural philosopher to depend on certain phenomena in nature, and which cannot be deviated from without giving offence to the ear: therefore a knowledge of these laws is considered absolutely requisite to every one who wishes to cultivate that pleasing art. This is precisely the case in regard to colouring; for it does not matter under what circumstances a variety of colours is presented to the eye; if they be harmoniously arranged the effect will be as agreeable to that organ as harmonious music is to the ear, but if not so arranged, the effect on the eye must be unpleasant, and the more cultivated the mind of the individual the more annoying will such discordance be.

On the harmony of colours he says, "If we look steadily for a considerable time upon a spot of any given colour placed on a white or black ground, it will appear surrounded by a border of another colour; and this colour will uniformly be found to be that which makes up the triad, for if the spot be red the border will be green, which is composed of blue and yellow; if blue the border will be orange, composed of yellow and red; if yellow the border will be purple, making in all cases a triunity of the three primary colours—red, blue, and yellow, the three simple or homogenous colours, of which all others are compounds. This analogy will help to show that the laws which govern colour are as irrefragable, and at the same time as practically necessary to the colourist in art, manufacture, or decoration, and, I would add, to the gardener, as those which govern sound are to the musician." Also, from the combination of the primary colours the secondary arise, and are orange, which is composed of yellow and red in the proportion of 3 and 5; purple, which is composed of yellow and blue in the proportion of 5 and 8; and green, composed of yellow and blue in the proportion of 3 and 8.

Contrasting Colours.—Yellow, its contrasting colour is purple; orange, its contrasting colour is blue. Orange is the extreme point of warmth in colouring, as blue is of coldness. Red, its contrasting colour is green. Red is decidedly a warm colour. Purple is rather a cool colour, and very retiring in effect. Blue is the only absolutely cool colour; the contrasting colour to blue is the secondary orange. Each of these colours is capable of forming a key for an arrangement to which all the other colours must refer subordinately. This reference and subordi-

nation to one particular colour, as is the case in regard to the key-note in musical composition, gives a character to the whole. The succession of colours in the key are yellow, orange, red, purple, blue, neutral, green. The diagrams given are also worthy of particular notice as showing a series of hues for each of the primaries.

The true knowledge of colour is not to be acquired by theory; some people have a false taste, some a false perception, which is otherwise called "colour-blindness." A true perception is a natural gift, like an ear for music, and it may be cultivated, but cannot be acquired. To attempt to find the reasons why one colour harmonises with another is futile until we have obtained a full empirical generalisation.

The last and best work on colours is by Sir J. G. Wilkinson, published in 1858. The following paragraph is valuable as a guide in our arrangement of colours in the flower garden:—"Colours are opposed to each other in different degrees. 1st, The strongest opposition is by positive contrast where the colours are of different hues and natures—as black and white, blue and orange, scarlet and blue, &c. Of these Mr. Field says, 'The only two contrasting colours which are of equal powers are black and white, orange and blue; and all other contrasts are perfect only when one of the antagonistic colours predominates. 2nd, Opposition or contrast of warm and cold colours; among the former of which are red, yellow, orange, brown, red-purple, &c.; among the latter blue, grey, green, purple, white, blue-black, &c. 3rd, Opposition or contrast of dark and light colours, or opposition of tones, as where the colours are tones of the same hue, one stronger than the other—as dark and light yellow. 4th, Opposition or contrast of accidental colours is where a colour and its accidental companion are opposed to each other—as red and green, blue and orange, yellow and purple.'"

From the attention that is now given to ornamentation in the arts and manufactures, and to a general diffusion of taste among all classes, we may soon expect to see the whimsical combination and the indiscriminate and incongruous mixture of colours, as at present very generally adopted in flower gardens, superseded by arrangements more in accordance with the true principles of taste. From the innumerable varieties of seedlings that are yearly raised with all the colours of the rainbow we can select the most suitable colours, and blend, shade, or contrast them as our taste becomes more cultivated. We must also bear in mind when arranging the colours in the flower garden that red and blue, which if mixed would form purple, become at a distance somehow fused by the eye into that colour, and that yellow placed next to red produces upon the retina the effect of an orange hue. But blue and yellow in juxtaposition do not produce green, or, if at all, to much less extent than the analogous secondary colours. Green has another peculiarity—that a certain quantity of it appears to be greater than the same quantity of other colours, and, consequently, a very small quantity of it will brighten-up a design. W. KEANE.

MANAGEMENT OF APRICOT TREES.

IN your No. 101 I felt much interested when I read the above heading, and I at once read through the three columns written by Mr. Robson. I quite hoped to have found some new method of insuring a crop of Apricots; but I cannot say that I found what I wished for. Still Mr. Robson is voluminous, and tells us that he believes the native country of the Apricot to be the southern shores of the Black Sea; that the Apricot attains the proportions of a fair-sized timber tree in Armenia (well, well, this is surely not far from the southern shores of the said sea); that the air of high regions is good for the Apricot; and that we have no mode of imitating this highly rarefied air; that the cause of our want of success is thus revealed; that "soil has no little influence over success;" that he is not quite certain he is right in supposing some of the old sorts are worn out, such as the Moorpark and the Peach Apricot, perhaps the oldest of all except the "Kill-John" of Africa (the Red Masculine).

Now, all this is interesting, I daresay, to many of your readers; but I confess I looked for some useful hints as to the "management" of Apricot trees, and also a full account of the districts in England where the Apricot tree is found trained against almost every cottage, helping to pay the rent; as Mr. Robson is, of course, a travelled man, for no writer on gardening should be a stay-at-home, I repeat I expected this from him.

As to the soils which Apricot trees seem to flourish in, they vary to a great extent. In Oxfordshire, where they are *par excellence* the cottager's tree, I think the district in which they are so numerous is oolitic. In Nottinghamshire, around Nottingham, I am inclined to think the soil is a stiff alluvial loam, but Mr. Pearson will tell us. In Suffolk, more particularly around Bury St. Edmunds, the surface is light, the subsoil mostly chalk; yet here Apricot trees flourish and bear abundance of fine fruit when trained against walls with south or south-eastern aspects. It is remarkable that in many gardens in the neighbourhood of Bury you may hear the gardeners say, "It is of no use to plant Peach trees here, they will not grow; but Apricot trees, as you may see, do well;" the soil of such gardens being a dark-coloured mould, very light and friable on the surface, and chalk and flints below.

Well, as Mr. Robson has written sixteen long paragraphs about Apricot trees, and has omitted to tell us many things, I will humbly attempt to give your readers a few hints taken from my own observation.

1. While Apricots against walls are in bloom, and the weather clear and sunny with sharp frosts at night, cover the trees every night with straw mats, or canvas, or some material capable of resisting frost to a certain extent. If the weather be dry the blossoms will take no harm, even if the temperature of the surface of the wall be as low as 27°. At 9 A.M. remove every covering, and never fail in doing so.

2. Never place any covering over the trees either by night or day if the weather be mild. Avoid all branches of evergreens as "protectors." If too thin, they are of no use; and if too thick, they will create stagnant air and destroy the blossoms.

3. As soon as the fruit is set and about the size of small horse beans, they are, if possible, more liable to injury from frost than the blossoms, and must be protected on frosty nights, but not in mild weather.

And now allow me to say why I have given the above hints. For twelve years I have cultivated Apricots in orchard-houses, and till last year my principal trouble has been the thinning of the fruit. During this period I have always observed the anthers disinclined to shed their pollen unless the weather was bright with a cold dry wind, our usual spring weather, thus showing that moist stagnant air was unfavourable to their performing their office. I particularly observed this last spring; the pollen was never dry and dusty as it should be, but remained on the anthers in almost a glutinous state. My Apricot trees in my orchard-house have been in bloom for more than a week, but till the 4th inst. the anthers did not open kindly. The bright sun and drying wind of yesterday (the 5th), however, settled the matter, and the pollen flew off in little clouds of yellow dust—a sure sign that Nature was fulfilling her office. My orchard-house, in which the Apricot trees stand, has been open night and day in spite of slight frosts for the last fortnight.

Mr. Robson "has but little hopes" of the Apricot as a house fruit. He saw it in 1829, and "that was a failure;" let him come here and see what a decent amount of intelligence and attention to the laws of Nature can do. My trees, with their roots "cramped-up" in pots, are as sturdy as oaks; and some of them, now from ten to twelve years old, have thick stems and sturdy heads, with short, well-ripened shoots literally covered with blossoms. Apricot trees planted out in orchard-houses do not come into bearing so quickly as potted trees. They are apt to grow too freely for some years; but I have some that are now eight or ten years old that bear profusely. In pots trees only 9 inches high will give fruit, and when pinched-in they are beautiful miniature trees.

Lord Elgin, just after his return from Japan, happened to pay me a visit when these little Apricot and Peach trees in six-inch pots were in full bloom. He at once said, "Why, how did you manage to import them in such good order from such a distance as China or Japan, where, only, I have seen such trees?" I soon made him aware that they were of home manufacture. No Apricot from a wall can be compared to the same fruit from an orchard-house. In the town gardens at Cheltenham I have seen Moorpark Apricots, from a standard, of very good quality; but waiting for a crop year after year is disheartening, hopeless work. Here, in a stiff loamy soil, I had at one time a standard Breda Apricot growing: its branches spread over many square yards of ground, and its trunk was several feet in girth. An Apple tree of the same size would have borne twenty or more bushels of Apples. Well, once in seven years it gave a crop of several bushels, which, if the summer were very warm, would ripen so

as to be fit for a schoolboy to eat. In the intermediate years a few were occasionally to be seen on it; and so, tired of the tree, I cut it down.

As to planting an Apricot tree against a north wall with the hope of eating ripe fruit from it, you might as well expect ripe Pine Apples from the open air in Kent. There is no wearing-out of old sorts of Apricots. The Peach Apricot, the finest and oldest sort cultivated in France, is now planted there to a greater extent than ever; and, as I learned from a French orchardist from the south, thousands of trees are planted annually to supply the markets, not as standards as formerly, but as "cordons" or close pyramids, the shoots being pinched-in in summer.

Mr. Robson recently has had a fling at orchard-houses, I may say as usual. Now, unlike your amusing and instructive contributor, Mr. Fish, I firmly believe he has never tried to manage an orchard-house. If he has, and has failed—well, the less he says about them the better. Let him come here and see, and I will endeavour to in-sense him, as Paddy says, as to the management and advantages of orchard-houses.—THOM. RIVERS.

THE ROYAL HORTICULTURAL SOCIETY'S KENSINGTON GARDEN.

It is impossible to please every one, and this is more especially true in matters of taste, such as ornamental gardening is. No work of man's hands is perfect—there is none such in which some fault cannot be found. No sooner is a work completed than suggestion after suggestion is offered as to how it may be improved. Where improvement is really the object in view these suggestions are not only welcome but oftentimes valuable, yet too often they are made with merely the desire of gratifying individual crotchets; and of both classes of suggestions this Society has had a full share. Some critics, regardless of cost, would have the Society's new garden gay with flowering plants at all seasons of the year; others, without reference to time, would have the garden planted with stately trees and luxuriant shrubs; and a third party would direct the funds of the Society to objects purely useful. All are right to a certain extent.

The purpose for which this Society was originally instituted was "the advancement of horticulture in all its branches, ornamental as well as useful." This should never be lost sight of; for it is a great point for any man, or body of men, to have a settled object; and the attainment of that, if steadily pursued, is not easy is at least probable.

To the Kensington garden belongs the ornamental; to the Chiswick garden the useful; but of the former it is now our business to speak. Both are under the management of Mr. Eyles, and with this twofold care upon his hands he has acquitted himself with great ability towards both.

Of the Kensington garden, to which we now restrict our notes, it was stated at the annual meeting, that in the previous season much had been done to render the gardens attractive at a time when the majority of the members and their friends could not enjoy the attractions which were presented; and, on the other hand, it was urged that the garden should be rendered even more attractive in winter than hitherto. Between these conflicting desires a happy compromise has been made; and without going to an enormous expense, the gardens have been rendered gay, whilst much of that flatness and deficiency in trees and shrubs which they hitherto presented have, by judicious planting, been removed.

At this season it is almost hopeless to endeavour to tempt any but the most hardy to prolonged out-door walks, accordingly the display of flowering plants is chiefly confined to the large conservatory. On entering this and passing along the broad central walk, on each side are fine Orange trees in tubs, with very superior-flowering Camellias here and there, and Rhododendrons, &c., at the back; whilst at the base of these are ranged rows of gay Duc Van Thol Tulips, Hyacinths of various hues, Cythususes, Deutzias, dwarf Camellias, Alma and Flower of the Day Geraniums, with a row of the *Isolepis gracilis*, which makes a very graceful edging to the whole.

Occupying the centre of the main walk is a very gay polygon bed, having in the centre a fine plant of *Cyathæa medullaris* surrounded with Lycopod; then comes a band of white Hyacinths, then one of blue, and nearer the edge a brilliant band of red Van Thol, the whole being bordered with Golden Chain Geranium with Lycopod interspersed. Although this bed was striking, the Van Thol Tulips seemed too powerful for the other colours.

employed, and to prevent the eye resting on these so much as it ought to do.

At the intersection of the main walk with the cross walk running to the south doorway, are several fine Camellias gay with their white and rose-coloured blooms; together with white Azaleas, *Kalmia latifolia*, Lilacs, and *Spiræa prunifolia*, the double white flowers of which are very ornamental; whilst in front on the walks are bands of Golden Chain Geranium.

But it is at the south side that the conservatory presents its gayest aspect, for there the whole of the flower-baskets, or brackets, which are placed at intervals along that side of the house for a length of 80 or 90 yards, are filled with Hyacinths, Tulips, and other early spring flowers, arranged on a conical elevation with excellent taste. The whole, especially when viewed from one end, affords a most striking and brilliant scene, and such a glow of colour as probably is nowhere else to be met with at the present season. The opposite side of the walk is likewise made gay by a miscellaneous collection of flowering plants ranged throughout its length in front of the shrubs.

On entering the door at the west end, the first basket we come to is, like all the others of which we shall speak, edged with Lycopod; next to this is a band of Voltaire Hyacinth, bluish; then a band of Diebitz Sabalkansky, and another red kind; next a pale blue sort; and the centre is filled with *Dielytra spectabilis* and *Azalea amens*.

The second basket had Lily of the Valley and Chinese Primula alternately; then came a band of pale blue Hyacinths; next to this a band of double rose, and the centre was filled up with plants for foliage and two tree Mignonettes.

The third had Lily of the Valley, then red Van Thol, mixed blue and white Hyacinths, the centre being filled with a Rhododendron and tree Mignonettes. The appearance of this was rather formal and not altogether pleasing.

The fourth consisted of yellow Duc Van Thol and white Hyacinths alternately; double blue Hyacinths formed the next band, within which was a band of double white, the centre being occupied by a deep rose Azalea and two plants of *Richardia ethiopica*.

The fifth basket had a band of blue and white Crocus in front; next to this yellow Van Thols; then white Hyacinths, with an Azalea and tree Mignonettes in the centre. This had been a very nice basket, but was past its best when we saw it.

It would be tedious to state particularly how the remaining baskets were filled—the above will be sufficient for an example of the system adopted. The materials employed were Lily of the Valley, Chinese Primulas, and Crocuses in the front bands; within these, Hyacinths of various colours and Duc Van Thol Tulips; whilst the centres were filled with Azaleas white or red, *Dielytra spectabilis*, or tree Mignonette.

The arrangement of the plants in these baskets, we were informed, is frequently shifted so as to afford, as far as possible, a change to the eye of the frequent visitor.

Outside the conservatory the vases on the terrace-wall are filled with Crocuses, whilst bands of these are planted along the front, the arrangement of colours being a band of white, one of yellow, then one of blue, and next to the wall of the conservatory a row of Wallflowers. Among the Crocuses were planted a few Hyacinths; but, from the difference in height, they did not harmonise well together.

On the terraces in front of the conservatory and in other parts of the grounds several new beds have been formed, and these have been filled with Rhododendrons, Irish Yews, Aucubas, and other evergreens; whilst in some, flowering Thorns, Lilacs, and other flowering shrubs have been planted. The panel flower-beds have been filled with Tulips, Scillas, *Muscari botryoides*, &c.; but as these are not yet in flower we must defer noticing them till another occasion, merely remarking that elsewhere there has been a plentiful introduction of shrubs to fill up the vacant flower-beds.

THE PRINCESS OF WALES' BRIDAL BOUQUET.—This was prepared and presented by Mr. Veitch, of the Royal Exotic Nursery, Chelsea. Enclosed in Honiton lace, and most tastefully arranged, were rare Orchid flowers, buds of white Roses, sprigs of Myrtle, and the customary Orange blossoms. The Myrtle sprigs were sent from Osborne by the Queen's special directions, as their parent tree was raised from a sprig which had formed a part of the bridal bouquet Mr. Veitch had presented to the Princess Royal. Similar trees are wished by Her Majesty

to be raised at Osborne from the Myrtle sprays of the marriage bouquets of each member of the Royal family. When Her Majesty heard of Mr. Veitch being in attendance with the bridal bouquet last Tuesday at Windsor Castle, she graciously directed a ticket to be given to him for admission to the Royal chapel to witness the marriage ceremony.

CLOTH OF GOLD ROSE FROSTED.

I HAVE a Cloth of Gold Rose on a wall with a south-east aspect, which flowered for the first time three years ago, but was nearly killed by the frost, which proved so fatal to Roses and evergreens everywhere. It has long branches from 5 feet to 8 or 9 feet long, without a shoot, but on the top of each there are tolerably good branches. How should it be treated?—A SUBSCRIBER, *South of Ireland*.

[For this season let the Rose alone, fasten-in all the strong shoots to the wall, and merely shorten their points; prune all little short pieces back to a bud. If the plant is healthy these pieces at the top will bloom well. If the long branches are sickly from the frost, it would be best to cut the plant down in the autumn, mulch and protect it in winter, and allow the plant to push afresh.]

DESTROYING THRIPS ON CUCUMBER PLANTS.

LIFE has been represented as a constant warfare, a perpetual struggle with difficulties; and certainly the cultivator, whether the farm or the garden be his sphere of action, finds it so. Diseases new to his experience, or insect enemies never before seen in numbers sufficient to be formidable, are constantly attacking the objects of his care, and a certain amount of loss is generally incurred before the best means of prevention or cure is discovered. Even this Journal would be still more interesting if every successful struggle were recorded and the means which have proved effectual plainly described. Let me have a word on this subject with your readers.

I am quite aware there are some selfish people who like to obtain information, but would not willingly impart it. I look upon them as belonging to *Les Misérables*—they are beneath our notice, a contemptuous pity is all they are entitled to. But there are great numbers of clever men and good gardeners who are afraid of recording their experience, because some stupid fellow is sure to say, "Bless me! has John Smith only just discovered that? Why, that's as old as the hills!" Is any one less obliged to Mr. Thomson for telling us how new Grapes may be produced at Christmas, because some one may say they have been so produced before? Or would Stephenson have been less anxious to bring the locomotive to perfection if he had known beforehand that some would-be *savant* would advance the opinion that not only the steam-engine but the locomotive was known to the ancients?

Let us remember that newly-acquired information, though not exclusively possessed by us, may be valuable to many. I have been led into this strain of reflection from having incurred some loss and much trouble by that troublesome insect the black thrips. A letter was addressed to you some time since on this subject—"How to kill the black thrips on Cucumbers," and at that very time I was anxiously seeking a remedy, and for a long time without success. Many years since I found strong tobacco-water quite effectual when, as in the case of Azaleas of moderate size, the plants could be entirely dipped in the liquor. Last autumn I had a house of Long-gun Cucumbers, grown for experiment, in splendid health; some fruit cut about Christmas were declared by Mr. Solomon, of Covent Garden, to be the best he ever saw at that time of the year. Much to my vexation these plants became much infested with thrips. I not only tried every remedy I could think of, but asked every gardener who came in my way for information. One said the best way was to destroy the plants, clean the house, and plant again; another said he knew of a remedy, but it was a secret. I knew at once he was a fool; they always have a number of secrets to keep. On all hands I was assured the thrips was very difficult to kill, particularly on Cucumbers.

At last I wrote to Messrs. Griffiths & Avis, of Coventry, to ask their advice. Their answer was they were sure their tobacco-paper would kill it. My reply was, our house had been fumigated eight times in a fortnight, and the men said the smoke would kill them before killing the thrips. I received a letter by

return of post, saying they quite believed the men's statement, for no man could bear smoke of sufficient density to kill this troublesome enemy. They also kindly gave a list of instructions for fumigating houses.

First, never smoke if the sun shines; next, choose a still day. Never open or shut a door whilst fumigating; never use coals, but light a handful of brown paper torn into shreds, put it into a pot, and the tobacco-paper also torn into small pieces over it, and blow at once. Let the house and the foliage of the plants be as dry as convenient. Smoke two nights in succession.

In accordance with these instructions I procured a gutta percha tube, had a small brass pipe attached to one end of it to insert into the pot side containing the tobacco, passed the other end through a small hole in the door, and there connected it with a bellows. By this means the house was filled with a dense smoke two nights in succession, and I believe every insect killed. The plants were quite uninjured, and are fast recovering their health.—J. R. PEARSON, *Chilwell, near Nottingham.*

THE ROYAL HORTICULTURAL SOCIETY'S SCHEDULES FOR 1863.

(Concluded from page 183.)

I now pass on to the second great Show; and here one is again struck with the immense amount of prizes given to stove and orchidaceous plants, for which, in a great many instances, the plants that have done duty at the previous exhibitions will again make their appearance, these, with foliaged plants, absorbing £262 out of the £446 10s. offered for this portion of the Show. I have no doubt plantmen will hold up their hands in horror at the notion of there being any doubt expressed as to the wisdom of the expenditure, and will tell me this Vanda cost £30, and that Cattleya £25, and this exhibitor would not sell his plant of that *Phalenopsis* for £100. Very likely; but this is no test of the amount of encouragement flowers ought to receive. Tulips are sold at equally extravagant prices, or at any rate quoted; but the Society does not think of offering anything for them, and, mad as Tulip-growers are, they would not be so insane as to ask that their prizes should be measured by the quoted value of their bulbs; and on what principle is £88 allotted to amateurs in Orchids and £25 to nurserymen?

As to the expense of growing, I think that to be a question which, with all due deference to other authorities, I cannot but think has been over-estimated in the comparison. On what grounds have the Exhibition Committee required new greenhouse Azaleas to be shown in June? They will recollect that they begin to require Azaleas on March 18th, and to have them three months after. That is requiring a great deal, and can only be done by a constant system of retarding; but Azaleas are in their glory in May, and then is surely the time for new sorts to be shown; for, from their being new, there is every anxiety on the part of the exhibitor to get his plants into bloom and forward for growth as soon as possible; and by endeavouring to keep them back until the third week in June a full month's growth, and that the best in the year, is lost, and with valuable plants that is of some considerable importance. There is not the slightest reason why they should not be shown in May, and perhaps it only requires pointing out to have the evil remedied; for I know that exhibitors of new Azaleas feel the regulation to be injurious to them, and they are naturally anxious to make as good a display of the new sorts as can be done.

Surely the *Dracenas* and *Cordylines* might very well have been left to take their place amongst the foliaged plants, for if they be as ornamental as the Council seem to think—a point on which I, for one, beg to differ—an exhibitor would take very good care to put them amongst them; but if they be, as I think with few exceptions they are, stiff and unmeaning, it would be surely better to put them out altogether.

The arrangement with regard to *Pelargoniums* seems peculiar, nor do I quite see on what principle the prizes have been arranged. If May be the month for Azaleas, June is unquestionably the month for this very familiar and effective flower; and yet no difference is made in the number of classes between this and the May Show. In May, Fancies are divided into two classes—for nurserymen and amateurs. Why that arrangement should be altered in June I cannot quite see, unless it be to allow spotted kinds to be brought in; but then would it not have been better to cut off some of the prizes for those

classes where money seems to be so lavishly given, and to apply it here and elsewhere?

Tropaeolums are to be shown in June! Now I have grown some of these for years, and have generally some good and large plants, and they are always in flower in March, and their beauty quite over early in May. Why, then, the Council should persist in placing them in the June Show I cannot conceive, especially as they found that last year there were no exhibitors in the class, and never will be in June. Just as they have done wrong in requiring *Amaryllids* in February, so here is an error in the opposite direction—but worse, inasmuch as I think that it is a good object to get plants early in the year, and every inducement may well be given to that end; but to require *Tropaeolums* in June when there is an abundance of other more showy and attractive flowers is surely a blunder of greater intensity, and one would think, with past experience before them, it ought to have been avoided.

Calceolarias have been omitted altogether from the schedule this year; and this, again, seems to me a great blunder. We have latterly seen brought forward a class of flowers in which the colours of the herbaceous kinds have been united to plants of a shrubby character, and for the decoration of conservatories in the later summer and early autumn months have been much appreciated. It seems a strange proceeding, then, after having set people on to grow these plants, to suddenly put the ban on them altogether. I happened to be standing by one of the exhibitors of them last season—a nurseryman—and having noticed that in the brief space of time that I was there he received several orders, I ventured to express my surprise; and he then informed me that he had received on that day alone more orders than he should be able to execute for months, and I believe more orders than any other plant received at the same Show, and yet it is now to be excluded altogether! This does not seem to be a wise way of commending the Society to the goodwill of all classes.

May I not put in a plea here for some flowers wholly omitted as well as the *Calceolaria*? Some weeks ago Mr. Carey Tyso, of Wallingford, took no little trouble in endeavouring to procure the names of the best show *Ranunculuses*, as so considered by different growers, and these lists were published in a weekly contemporary, and from thence copied into other gardening periodicals; but this flower is not one that the Royal Horticultural Society chooses to honour: it is excluded from their schedules altogether. The same may be said of *Pinks*, which are generally in their prime about this time, and around the boxes of which, when they are sent in for the Miscellaneous class, there is always sure to be a crowd of eager visitors and admirers. To have done these things after the strong representations of the Floral Committee, and after the opinions so freely expressed, of which some of its officers cannot be ignorant, augurs surely an amount of perversity one would hardly expect to find in a public body.

In making these strictures on the Society, I am in no way influenced by a desire to find fault. I wish it were everything it ought to be; but while so many blunders are perpetrated, it can never thoroughly enjoy the confidence of the exhibitors. Nurserymen especially are ill treated. "We get," writes one of the most successful of the exhibitors, "at the shows but scant justice. After subscribing our money and making their shows, they now ask us to help them by advertisements, and yet come into competition with us as distributors of seeds." This is, I believe, pretty well the feeling of the trade in general, and will ultimately lead, if not altered, to the end which the same writer points out when he says the "Society should not be supported by the trade." It may come to this; and, notwithstanding a long list of aristocratic subscribers, the real bone and muscle of the exhibitions are amongst the nurserymen.

—AN EXHIBITOR.

THE HYDROPULT.

WE strongly recommend this to the attention of our readers, for, which is not always in our power to say, it fully comes up to this statement of its proprietors:—"It is a fire-annihilator and garden engine, simple, effective, and convenient. It weighs but 8 lbs., and will throw 7 or 8 gallons of water per minute to a distance of 50 feet, when worked by the power of one man." It throws the water either in one stream, or dispersed in the form of the finest shower of rain, by means of a sprinkler which

is screwed on beneath the pistons, and which can be fixed when needed on the end of the jet.

Wherever a man with a bucket can pass there can the hydro-pult be brought into operation; so that narrow walks, and other places inaccessible with a garden barrow-engine, are no impediment to the approach of this very simple and very effective contrivance.

PARSLEY.

COMMON as is this kitchen-garden plant, and very often only indifferently treated, there is, perhaps, nothing which forms so universal an item in the daily wants of the household of a family of position; and it is far from being an easy affair to apologise to the kitchen authorities if it should not be forthcoming in early spring, even after an unusually severe winter. Such is the case now and then; and there is no doubt that the plant deserves a little more attention than it frequently receives, in order that its services may be reckoned on with greater certainty, if only to save the grower of herbs from some not-over-good-tempered mistress of the saucepan, who, in cases of "No Parsley!" may give vent to her disappointment in terms anything but complimentary.

After a very severe winter—such, for instance, as that of 1860-61—Parsley, as well as many other things, suffers sadly. In that winter many plantations were wholly destroyed; and what was left was rendered so weak that, excepting where precautions had been taken to leave some under cover, the supply for some weeks was very limited. In mild winters this evil is not so likely to happen, but it sometimes does so from other causes. Plants die off, and the dearth is equally great. As a means of preventing these calamities, let us look at the common practice and compare it with that likely to be more successful, and in fact proved by experience to be so.

In very many gardens it is not unusual to sow rows of Parsley as edgings to the walks bordering other crops. For instance: A square or plot consists of several kinds of vegetables, and a row of Parsley is sown as a boundary between them and the walk or pathway. This practice is not only excusable but highly to be recommended, only it must not, as is frequently the case, be done too often, otherwise the ground becomes tired, and the plant dies-off at the trying time in winter. It is, therefore, better to change the ground every time a fresh crop of Parsley is sown, and by that means one of the evils will at least be lessened if not entirely removed; as this change of soil is equally necessary whether the plant occupy a single row or part of a bed, border, or plot, the practice of sowing Parsley where it is most convenient to get at when wanted will not bear carrying out too long.

Wireworm is also another cause of Parsley dying-off. The root, thick and fleshy as it is, is nevertheless eaten through by these pernicious intruders; the top withers, and on examination it is found to be separated from the root an inch or so below the surface. The best remedy for this is a liberal dressing of soot and wood ashes, and, in default of these, lime is useful; but it must be used more liberally, being dug into the ground at the time of sowing, and a dressing given afterwards. Some soils are so much infested with this pest that it is not an easy matter to save Parsley over the winter; other crops, it is needless to say, suffering also.

Perhaps the most certain way to secure a supply of good Parsley in the months of February and March is to take up some plants in autumn, remove a part, but not all, the leaves, and plant them in boxes, pots, or pans, not too shallow. Place these for a time anywhere in shelter, removing them about Christmas to a warmer place where they will have light; and by the time above mentioned there will be some excellent Parsley, if the variety be good and other circumstances favourable. Digging up the frozen ground and carrying the hard-frozen plants at once into a hot vinery or other forcing-house, at a temperature of perhaps 60°, is an unnatural process; and though it will succeed, as we all know, it does so because the plant is so extremely hardy as to be difficult to kill, still the process carries its own impropriety on the face of it. A gradual forcing is unquestionably the best for everything that has to undergo that ordeal—Nature performs all her operations in this gradual way.

With regard to the proper time for sowing Parsley in the open ground much depends on the season. I generally sow a quantity in April and another batch in July. The seed lies longer in the ground before germinating than that of most other

vegetables, Celery perhaps excepted. The plants ought to be thinned, and they also bear transplanting pretty well. The main point is to have the ground deeply cultivated rather than enriched at top, in order to entice the roots downwards, and thereby lessen the chance of running to seed in August; but nothing can prevent the plants from doing so in spring, for after a year's growth Nature's law must be obeyed, and it is vain, by repeatedly cutting-out the seed-stems, to attempt making them into nice useful plants again. Other plants ought to be coming on to succeed them. The plant, being a sort of biennial, dies-off after ripening seed. It is, therefore, advisable in spring to stop the seed-stems of a few in order to obtain some leaves for garnishing while the new crop is coming on, the remainder being destroyed if not wanted for seed. I may also observe that it is a good practice to cut down a good batch of the most forward Parsley in the first week in September, in order that it may make a fresh growth before winter. Another portion cut once, a fortnight or three weeks later, will also furnish a later lot, taking care to insure always plenty to serve the purpose of the time being, as well as that which is to come.

It is needless to enter into the respective merits of the varieties of this plant, for every one knows what good Parsley is. It must be borne in mind that the finer the variety the more delicate it is. A plant or two of a plain kind will endure a harder winter than anybody's "Improved." This loss of constitutional hardihood is a sacrifice to improvement which other things as well as Parsley have to suffer; but in the case of the plant now before us the remedy is tolerably easy; it is only to protect a little and the object is attained. And, though Parsley likes good ground, that grown on soil of a medium character, not too rich, is more likely to stand the winter well, other things also being favourable.

J. ROBSON.

HYACINTHS.

THE lovers of this flower—those at any rate within reach of London, will have for the next fortnight an opportunity of seeing a fine sight, in Messrs. Cutbush's annual exhibition of these and other spring flowers at their nursery at Highgate. It has never been my good fortune to be in London at that time, but I hope this year to be more favoured; and although the season has not, generally, owing to the cold and wet time in Holland during May and June, when the bulbs were ripening, been as good a one as usual, yet I believe that Messrs. Cutbush's exhibition will be in no way behind those of former years. Probably it will be the more valued, from the fact that the show for them at the Royal Horticultural Society was fixed in February, and that unless the enterprise of our leading growers induces them to come forward, we shall not see the same display as in March last year. The task of describing Mr. Cutbush's exhibition has fallen generally into the better hands of Mr. Beaton. I am sure that I am only expressing the sentiments of every reader of THE JOURNAL OF HORTICULTURE, when I say that we all regret the absence of his genial and chatty pen, and to know that that absence is occasioned by illness, and that we, one and all, heartily trust that he may soon reappear amongst us, to be cheered and welcomed as an old friend.—D., Deal.

EFFECT OF GISHURST COMPOUND ON FRUIT BLOSSOM-BUDS.

HAVING continued my experiments with a view to ascertain under what circumstances Gishurst compound can injure fruit-buds, I have obtained the following results, which I am induced to send to you in consequence of an article in your Number of 10th inst. The first instalment of my trees were, in consequence of the season being so early, washed early in December, the solution being 8 ozs. to the gallon, fresh dissolved some forty-eight hours previously as recommended; the next instalment of the trees early in January. Neither, at the time the solution was applied nor a month later, showed any apparent effect; except in the cases of a few not-healthy trees, hardly a bud was touched on most of the trees—none on Apricots, Plums, Apples, and on the great majority of Peaches and Nectarines. Some of the Pears had a number of buds destroyed; others, Winter Nelis for instance, had not one. The trees which lost most have enough left for a full crop. I should have said that the trees were more thoroughly sowed than they are at all likely to be in other hands, the object being to have the extreme effect of the strength.

Having thus proved that 8 ozs. might be so applied as in some cases to injure buds, I then proceeded to ascertain what strength or mode of application would not injure; and having some trees purposely left unwashed, I operated on these at the end of January, when in my early situation the buds had come forward considerably. Some trees I washed with 8 ozs. to the gallon, and a few minutes afterwards washed with plain water; others I washed with a four-ounce solution without any after-water-washing.

In the more susceptible of the Pear trees some of the buds, washed with the eight-ounce solution were injured, notwithstanding the after-water-washing. Those to which the four-ounce was applied had, notwithstanding their forwardness, no buds touched. Under these circumstances, though except in a few exceptional cases, I shall continue on my own trees the strength I have always used—8 ozs. to the gallon, believing that the increased health of the trees, making more blossoms set, more than compensates for any buds that may fall off. I shall be disposed to recommend 4 ozs. in future to amateur gardeners, especially when their trees are washed when not entirely at rest.—GEORGE WILSON.

COCOA-NUT FIBRE DUST.

LAST year, in March, I received a supply of refuse from Kingston-on-Thames, and thought I would ascertain its properties and communicate the result to THE JOURNAL OF HORTICULTURE. I hope, therefore, that the remarks I am about to make will be taken in the light in which they are given; that being simply to state what I did with it, and what results attended the application.

Under my care is a fernery 42 feet by 23, which is formed into a grotesque-looking place by some sixty cartloads of sandstone containing a considerable amount of quartz. The interstices between the stones are filled with peat, loam, and silver sand, forming a good compost for Ferns in general. The plants did moderately well in this compost; but I must confess they cut a poor figure in comparison to their allies in an adjoining house, which were grown in pots crammed with the cocoa-nut fibre dust. It was this contrast that induced me to treat the Ferns in the house mentioned to a top-dressing of the dust. The house is exclusively devoted to greenhouse Ferns, and I may mention that several so-called stove varieties thrive well in it. The whole of the plants were mulched 3 inches deep with the dust in its rough state; but some strong growers received a double mulching.

When completed the appearance was neat, and gave quite a new feature to the place. So well did it look that a traveller in the trade noted down the place whence the material came; he obtained some, and he declares it is a bargain. Visitors also liked the stuff, for it looked so neat, no guano wearing a more golden aspect, nor being liked so well by vegetation, and in handling it does not soil the fingers.

After one season's growth the plants in the fernery had grown more in the refuse than they had done in two years before the refuse was applied. For instance: A "set on" plant (a term very familiar to gardeners, and which means a plant that refuses to become vigorous under proper treatment), of *Dicksonia antarctica*, with six fronds 2 feet long, put forth two fronds in spring, which I presume were the concentrated growth of the previous summer; but at midsummer, three months after the refuse was applied, six fronds began to show, and ultimately air-roots were put out from the short stem; the proper roots matted the refuse like turf, and the fronds attained 6 feet in length. Other six fronds appeared late in autumn, and they placed the "set on" plant in a position to grace, whereas it previously shamed, the skill of the cultivator. In its heart is the promise of another season's growth far exceeding the last, and it has gained 1 foot in circumference of stem during the last year. Would it have recruited itself so as to be vigorous without the refuse? It had the chance to do so for two summers, but it became weaker instead of stronger.

Take another example. *Woodwardia radicans*, fronds 3 feet long and proportionately strong, became so luxuriant that it strives hard to lift Hartley's rough plate glass off the roof, but being foiled in the attempt, its fronds, 9 feet in length, droop gracefully, the plant nearly eclipsing all its brethren from temperate regions for beauty, and, in fact, for its engaging peculiarities; but in general cultivation it is presented in browned fronds, stunted habit, and starved as often for heat as for

nourishment. Though said to be hardy, it is not so here. True, we have seen it just miserably existing in some places out of doors, but let those who wish to see *Woodwardia radicans* in character, prepare a vase full of refuse dust from the cocoa-nut fibre, put in the plant and place it on a pedestal in a cool greenhouse fernery, where, under ordinary cultivation, it will form a grotesque, picturesque, and gardenesque object, disputing the palm with all the drooping Ferns from every zone of our globe. In fact, I challenge the world to find a subject amongst all the varieties better adapted for an elevated position than the common and ill-used *Woodwardia radicans*.

In short, this dust is the best of all composts for Ferns; but the "old" is better than the "new" for pot Ferns, whilst the new is better for mulching purposes. Small-growing Ferns do very well in the pure refuse (old), but I cannot forbear adding a little silver sand. In fact, some of the delicate sorts, as *Ocheilanthes* sp., and *Nothochlenas* become too weak in the stems (stipes), without it, so as not to be able to support the frond in its proper position.

I also consider it wise to give the usual quota of sand to all plants, for I cannot see how silica can be present, in a vegetable substance, in sufficient quantity to meet the requirements of plants. Chemists say it is so, but I have seen the farmer obtain only half a crop from an over-luxuriant field of corn, whilst his next-door neighbour had a splendid crop from half the manure. With due deference, therefore, I dissent from the opinion that there is ample silica in all soils and manures to meet the wants of all crops. When there is an excess of manure applied the soil fails to yield silica in proportion to the growth of plants: consequently, the wood, ligneous or herbaceous, is gross, lacking those very constituents which give the wheat-stalk its strength.

I find this refuse dust is a compost for all plants requiring peat soil, or decaying vegetable matter; but it acts not only as a compost, but as a manure on plants requiring loam: therefore, as there is little silica in proportion to the other constituents in vegetable soil imperfectly decomposed, it is essential that a supply of the deficient ingredient should be applied by the cultivator; but in loamy soil, deficient for the most part in vegetable earth, an addition of the inorganic elements, particularly silica, would be superfluous.

Some Ferns like lime—as *Asplenium ruta-muraria* and *Polypodium calcareum*. Others require silica in considerable quantity—as *Blechnum spicant* and its varieties, and, indeed, nearly all Ferns from alpine regions, but the strong growers are not particular about the matter; yet loam will afford something of the inorganic but not inactive ingredient—sand. In spite of chemists and philosophers, I say that no vegetable substance or animal excrement contains enough of the inorganic elements to meet the wants of vegetation; and he who raises his plants with an excess of organic matter will lose by the lank growths, the feeble structure, the flimsy petal, and the altogether badly-grown and ill-shaped specimen. I have tried plants without the usual quantity of sand, but I must say no plant liked the experiment, neither did I; and I should no more think of planting a *Cucurbit* in pure manure without expecting to see it gorged into disease, than I should to live luxuriously and escape the first pestilence that occurred.

The refuse, then, has proved with me the best of all composts for Ferns, in its pure state, and old for the small growers, with a sprinkling of silver sand or pieces of sandstone not larger than a walnut added.

Half fibry hazel or yellow loam, half refuse, old or new, does for large-growing kinds, and that with a little sand will grow well *Geraniums*, *Cinerarias*, *Fuchsias*, *Achimenes*, *Gloxinias*, *Begonias*, and *Gesneras*, in fact better than the usual composts. *Primulas* like it, especially *Primula farinosa*, *scotica*, *nivalis*, *cortusoides*, and *marginata*; and I recommend it as a good substitute for sugar-scum or bullock's blood to *Auricula*-growers, as it emits no effluvia, and is so much nicer to handle.

Terrestrial Orchids—as *Cypripediums*, thrive well in the refuse dust. *Billbergias*, *Æschynanthus*, and *Tillandsias*, also *Marantas*, *Caladiums*, and in fact any deciduous or evergreen herbaceous plant that I tried did well in it; but the names of these are too numerous to recapitulate.

Now, then, for woody plants. For Oranges it is a specific; but although I reported favourably of it last year for *Camellias* and *Azaleas*, I have to record something not very corroborative. Last year I took the precaution to mix a little loam and sand with the refuse; but, anxious to mend well, I imprudently

potted some Azaleas with the pure material, and instead of being old refuse as in the previous year, it was new. The plants languished and died, still I do not blame the refuse for this, but my own imprudence. An Azalea has a close ball, so by potting in loose refuse, crammed in too, the water passes through it without wetting the ball at all: the consequence is, that the roots are dried-up, and when they are gone the plant goes also. This was a hazardous experiment, certainly, but the plants were doomed to be thrown out, for they were too large for our small houses.

Others have been in an equal dilemma with myself, and although giving their vote for the refuse as a first-rate material for Ferns, Begonias, Gloxinias, &c., they prefer peat for hardwooded plants.

A florist who grows Camellias well had a few sickly plants, and he, fingering my refuse dust, ordered twelve bags; so when the parties just mentioned remonstrated against my recommending the refuse for Camellias, I went to see what he had made with his twelve bags.

"How do you like it?" "Very well." "That's strange," exclaimed I; "I had two gardeners from H—— last week, and they do not like it." "But, I do," rejoined the florist, "and I have been to the Midland station to see what they will bring a truck for." This was proof enough. My friend liked it, and stepping into his greenhouse he took me to a lot of young Camellias, only grafted last year, growing in the infallible refuse dust. Some were in flower, and I in a quizzing way said they were nothing extra. "Nothing extra!" said he indignantly; "look at the size and bright green of their foliage, the brightness of the colours of the flowers, their size, and feel for yourself the stoutness of the petals," all the while holding the flower in his hand between his fingers; "and," continued he "where will you find a better-formed flower?" The points were incontestible: therefore I simply said "it was an exception." "An exception!" quoth he; "but look here, in an adjoining house, for growth on my two-year-olds, none of your three-inch shoots, but a six-year-old plant in two years." That was enough; he had tried the refuse, and had become an enthusiastic lover thereof. He uses it, half loam, half refuse, with a good admixture of silver sand, or about one-sixth of the whole. He says, and his plants bear testimony to the fact, that it is good material for Acacias, Azaleas, Camellias, and anything requiring peat soil or leaf mould. He puts his bedding plants in with a sprinkling of the refuse; but he does not place an Azalea with a ball as hard as a turnpike road in the pure refuse as I did, but uses half loam and refuse, and gives the whole a sprinkling of sand, which is very different from potting in the rough refuse.

I tried what effect it would have on Rhododendrons; but as they grow so luxuriantly here, though the soil is a strong loam, the difference was not great, though decidedly in favour of the refuse.

Some one, Mr. Beaton, I think, hinted that the refuse would be a good compost for Melons. Unfortunately, I had not a frame at liberty, but in the first week in July I planted two plants of the American Ridge, one in a bushel of refuse, the other in loam, and two of Achapenorricher Melon in a similar manner, and treated them alike. Both set their fruit immediately, and as the season was far advanced a couple of fruits were only left on each plant. The American in refuse gave a Melon, large, deep green, changing to yellowish-green when ripe; flesh red; flavour poor, but late Melons are not over-well-flavoured in general, slightly netted; shape of fruit elliptical; weight of each fruit from the plant in the refuse, $1\frac{3}{4}$ lbs., and 3 lbs. 6 ozs. respectively. The plants in ordinary soil gave smaller Melons but of better flavour, the weight being 1 lb. 7 ozs., and 1 lb. 12 ozs. Achapenorricher in refuse afforded a Green-fleshed Melon, the rind netted and warted, spherical in shape, of a moderate flavour, flesh thick but melting, and rind no less thick. The fruits weighed 1 lb. 14 ozs., and 1 lb. 7 ozs. In common soil the fruits weighed respectively, 15 ozs., and 1 lb. 4 ozs.

My master, who is partial to Melons, pronounced these new kinds of Ridge Melons flavourless Pumpkins; but he cannot appreciate (and he is a judge), any other Melons than Scarlet Gem, Excelsior, Beechwood, and Egyptian. The Persian breeds, however, are equally good. The smaller the Melon the better the flavour, and the larger they are the more sugar is needed to season them.

A few handfuls of refuse sprinkled on the meadow made people inquire the reason of the place being different from the rest, and it shows itself now. It would be a good dressing for mossy-bottomed lawns.

Potatoes do well in it, and give an increase of weight over ordinary manure. From a nine-yard row of each the weight was—of manured Potatoes, 2 st. 8 lbs., and from the refuse dusted, 3 st. 4 lbs.

The rough refuse fibre appears to be a good substitute for peat for Orchids; but as I have not tried it with more than a dozen plants or so, and as I intend to test that material this season, I cannot speak decidedly. However, the results already attained are very gratifying.

In conclusion, I beg to tender my thanks to those who first proved the merits of the refuse dust, and more especially to those who made known the material, thereby placing in the hands of the small gardener and amateur a substitute for the not-always-comeatable ingredient peat, and even when it is to be had, not always of a suitable composition. Through writing to THE JOURNAL OF HORTICULTURE, my time has been seriously encroached on by private communications, and as this is inconvenient to me, I purpose, but reluctantly, to become an unlocated correspondent of this Journal: therefore, good readers and correspondents farewell.—G. A.

AERIAL ROOTS ON FRONTIGNAN AND CONSTANTIA VINES.

VINE-STEM INARCHING.

SOME Frontignan and Purple Constantia Grapes, which I have in the same house with Grapes of other varieties, begin at a certain stage to emit aerial roots, which dry-up, as the house is kept dry to ripen the crops, and the fruit becomes worthless. As this is not the case with other Vines (St. Peter's, Black Hamburgs, &c.) in the same house, it is evidently not owing to mismanagement inside the house; but, in all probability, the outside border should be of a different soil for Frontignan Grapes—perhaps of a hotter and drier nature. I should, therefore, be glad to know whether, if they were in a border by themselves and with a third or fourth of sand or gravel, you think they would answer better, though the soil should lose in richness? The present border is of the common description, as recommended for growing Vines, and is covered in the winter by tiles in order to protect it from wet.

Would you also inform me whether it would be difficult to inarch the stem of a Vine, about ten years old, low down? as, by this means, the pot with the young Vine to be inarched upon it could rest upon the floor of the house. The proper and best plan would be, I suppose, to inarch upon young wood; but the former, if feasible, would be the more convenient.—AN AMATEUR.

[You will help your Vines by pulling-off the aerial roots as they appear, which will force them to root in the border; then dig a drain or a deep well opposite them in the border, and work in some lime rubbish. If that does not have the desired effect, then raise the roots next autumn; at the end of September replant in fresh soil, of which lime rubbish may constitute a third. We should use that, broken bricks, and charcoal; but not sand or gravel.]

As to Vine-inarching, you may either inarch or graft before the sap is in motion; after that you can graft with a dormant scion after the leaves of the stock are expanded. The inarching in the growing period is most easily done when both are growing as you state. See "Doings of the Last Week."

ORCHID CULTIVATION, CROSS-BREEDING, AND HYBRIDISING.

THERE has been for the last few years a steady and unabating increase in the ranks of Orchid amateurs all over the country. Gentlemen of wealth, not only in England, which once reigned supreme in this respect, but also in Scotland and in Ireland, have devoted large sums in founding, and adding to, collections remarkable for their individual and intrinsic beauty; and all of them possessing an interest which we may look for in vain in any other of the great divisions of plants. To the great body of the people the allocating such large sums for, in many instances, such small commodities seems inexplicable and anomalous; but to those who have cultivated a taste for flowers, and who are accustomed to see the greater portion of the choicer subjects of Flora under cultivation, this division possesses an interest, both individually and collectively, such as to warrant any reasonable expenditure. Besides, it is well known that skilfully-managed

collections, remarkable for their rarity and beauty, are always growing into money, so that, commercially speaking, the sinking of such money is a profitable investment.

Superiority of cultivation, then, seeing that it is about a quarter of a century since the mode of growing them and classifying them into divisions and subdivisions became better understood, ought to be a marked feature in their history; for there has been no want, either of men to experimentalise and find out the best methods for promoting their growth and encouraging floral development, or means to carry out their views. It is very questionable, however, if the truth were known, how far we have upon the whole gained in this respect. Eight years ago, when the writer sojourned in the metropolis, Orchids were in better condition, evincing somewhat more superiority of culture than we can boast of at the present day; at least, judging from what was exhibited then in comparison with what was exhibited last season. This is a somewhat bold assertion, but it seemed to be the opinion of more than one, and of some of the exhibitors themselves. There are some private collections around London that are a credit both to the gentlemen that own them, and to the gardeners who superintend their management; but numbers of these are holding aloof from sending their plants to the exhibitions, and this branch of horticulture is not so strongly represented before the public as it actually is entitled to be.

It has been remarked with a certain degree of truth that Orchids are not difficult to cultivate. This remark holds good with everything else, only one requires to know and adopt the right method. A first-rate Orchid-grower, however, must be exceedingly attentive and vigilant, taking cognizance of their peculiar habits, in order to fall upon the best plan for accelerating and consolidating growth; so as, in the one instance, to make them proof against disease, and in the other to promote good flower-spikes, and flowers large and full of substance. This is a task far more difficult to accomplish than many would suppose, for it is one thing to have a collection that may be considered fairly grown, and another thing to have one coming up to the superlative style of merit. There is the temperature best suited to the constitution of the plant; there is the material for the promotion of root-action; there is the quantity of moisture that each and all require, and the time when it should be applied—all these matters demand more than a passing glance, or an off-hand dealing with, if it be wished to rise beyond mediocrity; and yet you will not find half a dozen men that adopt precisely the same method, and all, probably, are successful to a certain degree.

Some, for instance, grow *Phalanopsis* on blocks of wood without any foreign matter whatever; others grow them in pots, the predominating compost being charcoal and manure, which is about as diverse treatment as it is possible to conceive. They grow and root splendidly in the latter compost, if a little sphagnum is chopped up amongst it; but it requires a skilful hand to water them, and they must not be overwatered upon any consideration in such a compost, else the roots are presented with more moisture than they can absorb; and hence elongation ceases, their pores are choked, and they gradually rot away; their leaves of course suffering in proportion. But, more than that, such gross feeding subjects them to the very evil which was recommended to be guarded against—disease; and, when once these rare and fine plants are contaminated, it requires time to produce a remedial effect. But to go into this thoroughly, and discuss it as it ought to be discussed, would require a series of papers, for this whole Orchid-cultivation question admits of a more thorough investigation than what has yet been accorded it, for the sake of horticulture generally, and more particularly for the benefit of numbers who have begun founding a collection, and who, feeling their way step by step, are anxious to obtain reliable information in ascending the scale.

There is one peculiar incident in the seeding of Orchids which is sufficiently anomalous to be worthy placing on record; and if it should meet the eye of Mr. Darwin, I should be glad to know if any like occurrence has come under his investigation, and the conclusions deducible therefrom. There are in our collection a plant of *Cattleya crispa* and one of *Dendrobium cretaceum* that produced, in each instance, abortive flowers. The buds swelled and inflated themselves to a certain extent, but were unable to expand their sepals and petals, and I supposed at the time they would fall off and die. Not so, however. The foot-stalks began to assume a more healthy green, and gradually swelled and produced seed-vessels, so far as exterior appearance went as perfect as those that had flowered in the regular way.

This appeared to me all the more strange, for the organs of fructification were enveloped all the time by these sepals and petals, so that no insect or other agency could in the least affect them. I cut up the *Cattleya* when ripe, and it was full of the fine white chaff-like dust common to the whole genus. The *Dendrobium cretaceum* pods still hang on the plant.

Again, I have observed over and over again that flowers of an imperfect character, such, for example, as those wanting a petal or sepal, have a great tendency to go off to seed-pods; for Mr. Darwin correctly remarks that so soon as a flower is fructified the ornamental portion of it immediately fades, and the nutriment is absorbed by the organs of fructification.

But I have also had pods without the least manipulation from perfect flowers, and have tried them in various ways, in order to get what I believe to be the seed to germinate, all to no purpose. Mr. Gorse, of Sandhurst, Torquay, an enthusiast in all such matters, seeing a short article of mine in a previous Journal respecting the seeding of Orchids, wrote to me to know how I had succeeded in my various experiments. I replied privately to that note, and enclosed a packet of *Odontoglossum grande*, which brought forth the following reply:—

"I am much obliged for your polite note, and for the packet of seed of *Odontoglossum* which is enclosed. It was very kind of you to send it, though, after your failure, I should have had little hope of succeeding. But, my dear sir, the seed is barren. On careful examination with one of Powell's microscopes, with a power of 300 diameters, I cannot discover a single seed which contains an embryo. There is the long, loose seed-coat, ribbed and twisted, which ought to hold a naked embryo, as a minute opaque dot somewhere in its interior; but in no single example was the embryo seen, though the transparent tissue of the seed-coat would readily have allowed it to be seen if present. Probably your plants were not properly, not really, impregnated. I think Darwin has touched the real spring of the general failure of Orchids to produce seed with us. He has shown that no Orchid blossom is self-impregnating, that the pollen of one flower fertilises another, and that this is effected almost universally by means of insects, chiefly bees. But the ventilation of our Orchid-houses is so managed that few flower-probing insects find their way into them. I am myself only a beginner in Orchid-culture, and that on a small scale; but for you, or any other clever man who has a large supply of Orchids at command, I do not doubt that a promising field of experiment is open. If I had such an opportunity I would encourage the access of bees to my plants in flower by all means; and even catch bees of different species—honey bees, wild bees, humble bees from the garden and field—and turn them loose in the Orchid-houses. Thus I think you would get many flowers impregnated and have fertile seed in abundance. Veitch's successes are all hybrids; in these cases the impregnation was done by human hands, and of course was effectual."

Well, I thought this letter, which I received last October, was most interesting, and, what with this and Mr. Darwin's theory and experiments together, I set earnestly to work. In the first place I determined to experiment upon a *Phalanopsis amabilis*, crossed with the more delicate and pretty roses, thinking if I could but be successful it would be so much gain in the right direction. I took off the hood or capsule that covers the stamens—and really one cannot help wondering how each component part is fitted to one another—with the point of a budding-knife, and the gummy substance that holds the stamens to their position in the flower (for it is only an appendage, and can be taken off without the least scratch to the column), stuck fast to my knife in the same way as I presume it will stick to the insects in Java or the Philippine Islands, and to my delight I could carry it up and down the house *ad libitum*, or could even send it with the utmost safety to your office in Fleet Street, or to the laboratories of Messrs. Darwin and Gosse, so as to be fit for duty after arrival. I applied this to the pistil of *amabilis* with much earnestness and care, and have now a very fine seed-pod as the result.

Vanda tricolor was served in the same way with *Vanda insignis*, and with the same results; *Cattleya labiata* with a chance flower which came from *C. crispa*; *Oncidium Phillipsianum* with *O. leucochilum*; and some others, all with success. I was, of course, very much pleased so far, and I am very anxious to know whether I will be able to make them germinate. That point of the experiment yet remains to be tested, and I shall take an opportunity hereafter, if spared, to record the results.

About a month ago I crossed *Phalænopsis Schilleriana* with the new Bornean variety, and have a splendid seed-pod as the result of that experiment. There are several varieties of *Schilleriana*, some producing flowers much more perfect than others, and varying in shades of colour. Some, too, are much closer arranged on the spike, and show at once the correctness of the enunciation that a plant scarcely ever reproduces an exact likeness of itself.

The Bornean variety is much the best of all the grandiflora breed. Its flowers are larger, of greater substance, and of inimitable purity of white. Its form is as good as *amabilis*, both sepals and petals being larger and more full, and the flowers are so closely arranged on the spike, although not confused, as to give it a very formidable appearance. Its only damaging point is, that the edges have a tendency to turn back; and this, in a florist's point of view, somewhat mars its individual beauty.

To return to the experiments. I was curious to try my hand at hybridising; and having a nice plant, with a couple of fine flowers on it, of *Paphinia cristata*, I fixed upon trying to cross it with one of its terrestrial congeners—*Calanthe vestita*. In this I was also successful, for a fine pod hangs on the plant as a voucher thereto. I also hybridised *Limatodes rosea* with this same *Calanthe*, which has been done beforetime, I understand, with success, so that I did not value this hybrid so much. The pod of this is now ripe, and I will be enabled to enter into the second, and, to my thinking, most difficult part of the experiment.

Now, in conclusion, there are two points that I should like the scientific pen of Mr. Darwin to throw some light upon; and that is, Why these abortive flowers produce seed-pods to all outward appearance as perfect as those that have been impregnated? And why those flowers that never expanded, whose organs of fructification never were under the influence of light and atmosphere in the same way as other perfect flowers are, produced seed-pods at all?—JAMES ANDERSON, *Meadow Bank, Uddingstone.*

GALVANIC PROTECTOR FOR KEEPING SNAILS, SLUGS, &c., OFF FLOWER-BEDS.

PROFESSOR William Thompson recently, before proceeding to the regular business of the natural philosophy class in Glasgow University, said that a very curious application of Sulzer's experiment had been made known to him. This experiment, as they were already aware, was:—When a piece of copper or silver and a piece of zinc are placed one above and the other below the tongue, and then put in metallic contact with each other, either by direct contact between them, or by wires connected with them, and put with their ends in contact at any distance, an electric current was produced and felt in the tongue, this organ acting as an electrolytic conductor. He had great pleasure in bringing before them a practical application of this experiment for the purpose of protecting flower-beds from the inroads of snails, slugs, and other kinds of creeping creatures. He had not, indeed, seen it; but he had been assured of its success. The way to apply the experiment was as follows:—A zinc plate, the upper edge of which was bound with copper, and elevated 2 or 3 inches from the ground, was so placed as to encircle the plot of ground which was to be protected. When any creeping thing, attempting to get over this little wall, came in contact with the zinc and the copper, it experienced an electric shock; indeed, it could not be an instant in any position touching the two metals at once without such a result taking place. The question now to be solved was, whether the snail, slug, toad, or frog would be so sensitive as to be deterred and struck back by the amount of the shock which it received under these circumstances. Mr. George Edgar, who was the inventor of this remarkable application, had assured him that he had tried the experiment with leeches, and that it succeeded perfectly. Mr. Edgar was present and had brought what was necessary to test the application.

Mr. Edgar then came forward and made experiments before the class. He placed leeches both inside and outside a part of the table enclosed by a zinc wall with copper mountings. When the leeches crept so far up the plate that their bodies touched both the zinc and the copper, they experienced an electric shock, and fell backwards.

Professor Thompson remarked that Mr. Edgar had tried the experiment with snails and slugs, and found they were more

sensitive to the shock than leeches. As he had already remarked, the question to be solved was whether the creatures were strong enough to persevere in getting over the wall, notwithstanding the shocks they invariably received. He might add that it was not necessary that the bottom of the plate should be buried in the earth, as it was enough if the plate was so placed in the ground that the creatures whose inroads were to be prevented could not get under it. To prevent the zinc plate from oxidising by damp, &c., the lower part of it might be protected by a coating of paint, pitch, or some similar substance. Indeed, the plate might be completely insulated from the earth, all that was necessary for the electric effect desired being, as he had stated, zinc and copper in metallic connection with one another, so placed that the marauder could not get into the guarded precincts without touching the two metals simultaneously. Of course, if the zinc is well polished, the shock given is greater than with a tarnished zinc surface. If, therefore, this plan of protecting flower-beds and other plots of ground produced all the results which were desired and anticipated, it was possible enough that one of the duties of a gardener in a morning would be to go about and polish his zinc and copper enail-guard.

[This is no novelty. It was invented by Mr. W. Walker of Hull, and communicated by him to the Society of Arts as long ago as 1839. A full description with illustrative drawings are in London's "Gardener's Magazine" for 1841, showing how it is adapted to flower-pots and other garden uses. The metals becoming oxidised, and then ceasing to galvanise, require often to be rubbed bright with sand-paper, and this trouble has caused their disuse. Two or more makers advertised these plant-protectors at 14s. per dozen in the periodicals of 1841.—EDS. J. OF H.]

ARRANGEMENT OF TURF IN FORMING A GARDEN.

GRASS lawns are such indispensable features in modern gardens that few, if any, can be said to be complete without them. Sometimes a broad sweep of lawn is made the principal feature; but more frequently grass forms the groundwork to set off others, and well it is adapted to the purpose.

The time is at hand when lawns will give unmistakable signs that they require attention, that the scythe and the mowing machine must be set to work to keep them in order. This also is the time when many small gardens are laid out or altered; and as, more or less, grass enters into the composition of all, or nearly all, of them, a word on the subject may not be inappropriate.

It cannot but have struck many working gardeners that where anything has been attempted beyond the ordinary level grass plat and grass verge one important point has been entirely overlooked, or at least not sufficiently taken into consideration, and that is the time and expense necessary to keep it in proper order during the growing season. Large quantities of turf are laid in such a manner that neither scythe nor machine can be used on it. It is formed into such sharp angles, both horizontally and vertically, so thickly planted with shrubs, &c., or roots and rocks form such intricate passages, that nothing but the small hand-shears can be used to cut it, and this, it is well known, is a very slow method of grass-cutting.

I once knew an instance where a gentleman, who had an eye to the fanciful in gardening, had his garden laid out in such a manner that, although nearly half of it was turf, there was scarcely a part where anything but the shears could be used on it. It looked very well while the grass was inactive, but when the growing season arrived it was found that the ordinary labour was not sufficient by two-thirds to keep the garden in order; and as he had not calculated on the additional expense of employing another man merely to clip the grass, he found that he had committed a grand error, for of all things that tend to make a garden unattractive nothing is more effectual than neglected turf, and that still more so when formed into steep banks, narrow windings, and fanciful edges.

In very small gardens which take less time to manage, such intricacies of turf may be excusable, as it can be more easily controlled; but even here some consideration ought to be given to the time that can be spared during the summer for keeping it close and neat, as, where this can be done, some of the prettiest effects can be produced by a well-planned mixture of turf, shrubs, and flower-beds.

In gardens of any extent, where turf is extensively used, it is of importance to apply it to the best effect without incurring such an additional expense as may become irksome to the owner, or the chance of the turf proving a source of trouble and vexation to the gardener, for if true taste is economical in any one thing, it certainly is so in the matter of laying down turf; and I cannot see why it cannot be done to the best effect where the scythe or the machine can be used effectively. Gentle slopes and undulations of turf generally look well, and these can be mown; but steep banks are, in my humble opinion, neither attractive to the eye nor comfortable to traverse, and certainly I do not believe they compensate in any way for the extra time necessary to keep them in order.

In natural scenery I think we shall find that where ground is covered with a close herbage, the rise from low to high ground is gentle and gradual, and that steep descents belong to rocks for the most part barren; and although it is not necessary slavishly to copy Nature, we ought at least to keep within certain bounds and not stray too far from her teachings.

Every year new gardens are being formed, or alterations are made and, generally speaking, the whole attention is given to picture-effect, with scarcely a thought as to how that effect is to be maintained. Turf is laid just in such a manner and place as requires the utmost stretch of time to keep it as close as it should be. In the same way nurseries are ransacked for shrubs and trees of just such a size and height as are required for the moment. Many of them die, the rest become too large in a year or two unless they are severely punished to keep them within bounds. It would be greatly to the advantage of the owners to give a little thought beforehand to such matters, as, in selecting subjects for planting a new garden, how important it is to have young well-formed plants that are certain to live, giving in addition the pleasure of watching them grow; and also to lay the turf in such a manner that it can be mown off quickly and kept clean, unless it is considered preferable to see a man in his shirt sleeves at the everlasting task of clipping to keep it short.—F. CHITTY.

STROBILANTHES AURICULATUS.

THE order of Acanthads contains many pretty stove plants of the "soft-wooded" class, which, from their affording considerable variety, and from many of them being winter bloomers, are desirable in gardens where conveniences exist for the cultivation of plants of this peculiar stamp. There are the *Apelandras*, the *Porphyrocomas*, the *Schauerias*, the *Eranthemums*, the *Goldfussias*, the *Beloperones*, the *Ruellias*, the *Cyrtantheras*, and many other family groups, all yielding species of a more or less ornamental character; and though not quite so striking as some of these, there are some *Strobilanthes*, such as *S. Sabinianus*, and the subject of the present notice, which possess sufficient merit to claim admission, if only for variety's sake.

Strobilanthes auriculatus is a vigorous-growing branching plant, of from 2 to 3 feet high, bearing stem-clasping elliptic-oblong leaves, which are narrowed to the base, and strongly auriculate; they are hairy on both surfaces. The flowers come on short axillary branches, and issue as is usual in this genus, from a spike of imbricated leafy bracts, which, having the character of a strobilus or cone, seem to have suggested the generic name. They are very pale blue, prettily veined, and when a considerable number are expanded at one time, are rather attractive. Their defect is, that they individually fall too soon.

The plant is a native of the East Indies. We have no exact information as to its introduction to this

country. The plant was presented about the year 1850, to the Chelsea Botanic Garden, by Messrs. Henderson, Pine Apple Nursery, Edgeware Road. With us it has blossomed in February.

Nothing can be easier to cultivate or increase. It grows vigorously in a stove, if potted liberally into a free compost, which should not be too rich. To develop its ornamental qualities, a good plant should be grown on through summer and autumn, and then allowed a short rest. The excitement of additional heat will then cause it to throw out the flowering branches. To produce smaller blooming plants, cuttings taken from a nearly matured growth, will usually branch into flower, as happened with that from which the accompanying sketch was taken.—M.—(*Gardeners' Magazine of Botany.*)

Strobilanthes auriculatus.

VINEYARDS IN ENGLAND.—Out in the fields near the remains of Beaulieu Abbey, Hampshire, stand the ruins of a building, now a mere pinfold for cattle, called by tradition the Monk's Wine-Press, whilst the meadows beyond, lying on the slope of the hill, are still known as "The Vineyards." This term is still frequently found hereabouts as the name of fields generally marked by a southern slope, as at Beckley and Hern, near Christchurch, showing how common formerly was the cultivation of the Vine, first introduced into England by the Romans.—(*Wise's New Forest.*)

TAR OR ASPHALT WALKS.

IN some recent Numbers Mr. Robson has described the various materials of which paths and walks may be made, and the principles of their construction. May I add, as a supplement to his remarks, an account of the tar paths which are at present much used in this city by our surveyor of roads? The body of the path is made of the soft oolitic stone or other rubble free of dirt. This is brought to a tolerably even surface with the rake, and over it is laid about 3 inches thick of a hard mountain limestone, known here as Clifton Black Rock, which has previously been broken into pieces not exceeding an inch and a half in size, and these passed over a three-quarter-inch riddle to separate the finer particles. The stones are then very equally mixed with enough cold gas tar to cover every stone, but not to leave more fluid tar than can be avoided. They are spread equally with the shovel over the softer foundation, and when levelled are carefully rolled with an iron roller drawn by two men, to give a smooth surface. This is then sprinkled with about three quarters of an inch thick of the finer particles of black rock, whereby any fluid tar is absorbed and a finer surface obtained of a hardness equal to the stones. Of course, a dry day must be selected, as all the materials must be dry, otherwise the tar will not adhere to the stone. Four men will lay down a very long piece per day—the more pains are taken the better is the path.

At first the stones, covered with tar, were laid down without sifting; the result of which was that the path was never smooth, the larger stones cropping out and being uncomfortable to the feet. Where barrows are likely to be used, paving occupies the middle and the edges are tar paths. A better path or one more pleasant to use cannot be made, and the more it is used soon after its first formation the better it becomes. The objection to it is, that for some months in warm weather there is the smell of gas tar. It is very inexpensive, lasts for many years, and acquires a dull grey colour. One's day's work is easily joined to the piece made in the preceding day. The fear of the offensive odour led the City Act Committee to order in some parts paths to be made of puzzolana, ground lime, and stone, but these are at least one-third more expensive, and are not so pleasant for foot passengers. Blindfolded, one could notice that they do not possess the elasticity of the tar paths; nor is it probable that they will wear so well, the whole material not being so hard, while it is more brittle, it cannot be laid so smooth, and the joints are never good.

Some years ago I laid down some tar paths, running between Box-edgings, in my kitchen garden. They were made with boiled tar and sifted rubble; but from further experience I should not now adopt them, for the Box is killed where the tar surrounds the stems, the weeds grow between the edge of the tar and the Box, and the materials of the walk rise at the edge, so that the whole path becomes irregular in two years. This, probably, would not occur if slate or wood-edging were used; but it must always be remembered that if the soil below the tar or cement paths be damp, the first hard frost will make it rise, and large patches will peel up. Paths of the above description answer best when flanked by a wall, and when above the level of the soil; if below it, or not thoroughly drained, they soon perish.—A BATH MAN.

SHADING FERNERIES.

SOME reader of this Journal may have a fernery requiring shade from the sun's rays, and may be anxious to know of a cheaper mode of shading than by using tiffany, bunting, hexagon netting, &c.

We had such a house, costing some £3 10s. annually in tiffany, which was more than it cost in heating. We wanted a permanent shading material, for the Ferns were planted out, and, therefore, not likely to be used for any other purpose for some years. I had some squares of glass, mixed some whitelead paint and painted three squares of various consistencies of paint, one thick, another medium, and one thin. Then, holding one of them to the sun, where the mercury was driven up to 104° in the full solar rays, I could see no sun through it, and a thermometer under the glass read 71°. That was the square painted with the thick paint, which was too opaque. The medium-thick paint allowed the light and heat to pass through the glass until the thermometer became stationary at 81°; that, also, was too opaque. That, however, with the thin paint on it could just be

looked at when held between the eye and the sun; and the thermometer under it rose to 86°.

I painted some squares green, others red, some blue, and more yellow. Then placing these together along with the white, I had contrasted shades or rays of light, but as red, blue, green, and yellow tinted the plants, though they did not alter the colour of the plants, yet these looked as if surrounded by a coloured atmosphere; but white-painted glass had not any such drawback: therefore I considered it the only colour fit for the purpose of shade, as it gave pretty nearly the same light as nature—I mean, allowed the light to pass through the glass untinted, unlike the other colours.

The painters were sent for, given the pane of painted glass, and told to paint the glass roof outside exactly like it. They hinted that to dash their dust-brush perpendicularly lightly on the painted glass would give it a frosted appearance. That was a first-rate suggestion, and therefore acted on.

The roof must be thoroughly dry before the paint is put on, and the internal atmosphere kept as low as possible, air given, and every means available taken to prevent water condensing on the glass, for water finds its way through the laps, and runs down the squares outside, leaving marks a quarter of an inch broad, and that spoils the appearance materially.

The appearance when completed was superb, and the utility of the plan was very great. The plants thrive well, and though gloomy in winter the plants keep their colour, and are in nowise drawn. The paint shading prevents the internal temperature from cooling as rapidly as with tiffany, and is not liable to become hot so soon—in fact, it gives a uniform temperature, becoming neither quickly hot nor soon cool, and that is what most plants that grow in shady places require. How long the painting will last I cannot tell, but ours has stood three years, and is as good as ever. A plan like this gave in three years some £7 for the gardener to buy something extra to gratify his master, which otherwise would have gone in tiffany.—G. A.

MORE ABOUT POTATOES.

AS "UPWARDS AND ONWARDS" has been giving a description of the best Potatoes he saw at the International Exhibition at South Kensington, so far as their appearance went, perhaps a few words from one of the exhibitors may not be out of place, stating their different habits of growth and eating qualities.

I will take first the first earlies, as they are the first ready for eating.

Old Ashleaf.—A capital cropping and superior eating Potato; but for exhibition purposes it is not a good one, as you would want to grow a bushel to pick twelve large ones from.

Red Ashleaf.—A good cropper, capital for exhibiting, but requires keeping a month or two before it is good to eat, and when boiled is too white-looking in the dish. Nevertheless, it is a good Potato, as it will keep as long as the late kinds and takes up very little room, being very short and close in the top.

Lemon Kidney.—A splendid-eating Potato, and looks a beautiful pale yellow when boiled; produces a great many at a root, but rather inclined to the disease if grown upon a wet soil. Altogether a superior early Potato, and just what judges like; a Potato fit for a gentleman's table.

Jackson's Seedling.—A capital Potato. I have taken prizes with this for both rounds and kidneys, and when digging roots up part of them will be quite round and others kidney-shaped. One or two of the judges in this neighbourhood say they are not good-eating, but I always found them good; perhaps the soil made the difference.

Myatt's Early Kidney.—A first-rate Potato for every purpose, especially for exhibiting, as nearly all of them are of a good shape. It is a good cropper and very early—nearly as early as the Lemon Kidney, but a better shape.

Sutton's Racehorse.—A first early kidney, a certain cropper, and capital eating, and one of the earliest grown; very similar in shape to the Old Ashleaf.

Early Handsworth.—A very early Potato with a very short top and good shape, round; but you cannot eat it, so who will grow it? If any one likes a Potato very waxy, this is the one for his taste.

New Golden Seedling.—A very superior eating and looking Potato, round-shaped, very early, and good cropper, with very dark foliage. This is all the first early Potatoes I grew last year.

The King.—Second early, a great cropper upon good land,

capital eating; the best for exhibition purposes for either round ones or kidneys, as they grow both shapes, some being as round as marbles, others good-shaped kidneys, both at the same root; a beautiful straw colour when boiled. This Potato took the first prize at every show I sent it to, including the Crystal Palace in 1861, for the best twenty Potatoes in the Show, first at Birmingham this last year, first for the best twelve kidneys at the International, South Kensington. They were also in two collections I had there that gained one second prize and one extra. This capital Potato was a seedling from the

Fluke raised by Mr. Spencer, of Hartshill, now living at Offley House, Eccleshall, Staffordshire. He has a lot of seed to spare. I sent all I had to Sutton & Sons, of Reading.

Webb's Imperial.—A good second early, a good cropper and eater, but very much inclined to take the disease; very long tubers; good for exhibiting.

Lapstone Kidney.—Second early. A very handsome tuber, splendid eating, but shy cropper, and very much inclined to take the disease.

Flour Ball.—Round, second early, a good cropper, good-eating white Potato, but the eyes too deep for peeling.

Bell Kidney, or *Second Early Ashleaf*.—A good cropping and eating Potato, but grows too many small ones, and the bulbs very much thicker at one end than the other.

Queen of the Flukes.—A late Potato, very similar to the Fluke, but better in shape, with pink marks at each end. This is considered by several Potato-growers to be the best eating of any of the kinds, quite superior to the Fluke; it is capital as an exhibition Potato. This was reared by Mr. Spencer with the King.

Red Regent or *Holland*.—A red round Potato, an immense cropper; indeed, it will grow a good crop where the Fluke would fail. It is a handsome Potato, and good for exhibiting; but when cut through some of the tubers are red all through, and when boiled are nearly black, so that it will not do for a gentleman's table. Nevertheless, it is a capital Potato for cottagers, as they do not mind the look as long as the tubers are good to eat.

Millet's Manifold.—A capital scarlet Potato, good for exhibiting, eating, and cropping; kidney-shaped.

Wellington.—A capital round Potato, but the eyes are rather too deep for peeling without waste.

York Regent.—A capital-eating round Potato, but very subject to the disease; rather a shy cropper for a late Potato.

Scotch Cups, *Farmer's Glory*, *Pheasant Eye*, *Bread Fruit*, and several others I grew, but found them too coarse to need description.

"UPWARDS AND ONWARDS" makes a mistake when he says the Rev. Mr. Stevens, from Reading, sent the King and Queen of the Flukes, for I believe I was the only exhibitor who sent them to Kensington. Mr. Stevens sent Webb's Imperial or Incomparable, and took the second prize, while my Kings gained the first for the best twelve kidneys.

I think, if I remember right, "UPWARDS AND ONWARDS" could not tell which were the best Potatoes out of the great quantity he saw. Did he notice Mr. Robinson's first-prize collection? There were twelve splendid-looking Potatoes named the Melbourne Hero. I liked these the best in the Show; indeed, I never saw anything like them before, as far as appearance went. I wish I had some of the kind. They were kidneys, and looked like second earlies. Next to these I thought my Kings were the best; but a competitor always likes his own the best.

I have received a schedule of the Royal Horticultural Society's Shows for this year, but there are no prizes for vegetables. Why is this? The Exhibition in October last must have answered.—J. CHOYCE, JUN., *Harris Bridge*.

FLUE-HEATING.

HAVING during the last autumn built a vinery and orchard-house, heated by a flue, I think I may be enabled to help the amateurs who, like myself, have been afraid of the expense of hot-water apparatus.

My house is a lean-to, 40 feet long and 15 feet wide, divided in half by a glass partition, the half nearest the fire being the vinery. The flue goes from the back through to the front of the house, within 5 feet of the glass, then turns along the front to the glass partition, and takes a slight curve to within 5 feet of the back wall of the orchard-house. In this house I have two

chimneys, one going from the curve mentioned before, the other in the far corner of the house, so that I can either have heat or not in the orchard-house, by allowing the smoke and heat to escape by either the one chimney or the other. My flue is formed of single brick walls $4\frac{1}{2}$ inches wide, 12 inches deep inside, 14 inches wide, covered by fire-brick covers, notched, to prevent any escape of smoke through the joints. The expense of the flue was, bricks and mortar, 20s.; cover, 20s.; labour, 10s.; showing a cost of 50s. My fuel costs me 2s. per ton, or with cartage, 1s., 3s. On the 19th of January I had in two tons, of which about 5 or 6 cwt. remain.

My Vines are showing fruit, so that you see I am enabled to keep up a good heat at a very small cost. I have five Vines planted in the border, and five more in pots, besides some Orange and Fig trees, bedding plants, &c. Another mode of heating which I feel certain will prove very good and cheap, is on the principle of hot water, but actually by hot air. We have it at work in our manufactory, and we find it heats a very large structure very effectively, and dries-off our goods in a very efficient manner. The principle is this:—In the furnace or fire-place a large cast-iron pipe is fixed, so that the fire plays all round it, and heats it thoroughly before going up the chimney. One end is open to admit the cold air, to the other end earthen pipes are attached, taking the heated air in any direction you desire, the circulation being as true with air as water, but only requiring a flow-pipe, and not a return one, causing a first-rate circulation in the house; and by keeping the earthenware pipe (unglazed) damp, you can have any amount of moisture you require. The heated air contains no impure vapour, as it is not at all unpleasant to stand in and breathe it, even at a high temperature. The cost is also very little, as the six-inch pipe we can supply at 9d. per yard, and the nine-inch at 1s. $1\frac{1}{2}$ d. per yard, at the works, or deliver them 100 miles at a very small additional cost, in two-ton lots. I shall be happy to give any further information that may be required, or to register the heat I keep, and my consumption of fuel. In my orchard-house, which is full of trees—Pears, Apples, Plums, Cherries, Peaches, and Nectarines, of various sorts, I am also forward, but as many were only maiden plants I cannot expect very much fruit; but the few fruiting trees I have look very promising, Peaches and Nectarines being in full blossom, and Pears and Cherries in bud.—E.

MICE DESTROYERS OF CROCUSES.

FRIENDSHIP BETWEEN A SPANIEL AND MOUSE.

SEVERAL letters have appeared in your Journal on the destruction of Crocuses, &c., by mice, and I have no doubt of their committing the depredations, for I have had mine destroyed by them. It is astonishing the numbers of these animals I have had in my garden, for the three cats I have have destroyed scores of them, and as they do not eat that species, they leave them on the walks and grass plat in front of my house, yet I frequently find five or six on opening my door in the morning. They are difficult to catch in traps, as they will not take any bait that I put for them; but my gardener has caught a great many by placing the traps in their runs in the turf pits and orchard-house and covering the trap with grass, leaves, &c. I have suffered in the same way as your correspondent "R. F.," having had a Sweetwater Vine bitten off by them close above the ground. They have also eaten the large roots, so that it is quite destroyed. I have had a very strong solution of Gishurst applied repeatedly to the other Vines to prevent the mice destroying them.

I may mention a curious circumstance relating to a common house mouse, which has made its nest in a corner of the standing in the stable where a large spaniel dog is tied-up, which protects it from the cat, and which yesterday flew at the cat that was just about to catch it. The mouse was protected in the same way last year by the dog, under whose protection it brought up its young ones, and it is about to do the same again.—R. C. B.

[Our correspondent is a physician, and old subscriber to this Journal.—Eds. J. OF H.]

TRADE CATALOGUES RECEIVED.

W. Paul, Waltham Cross.—*Spring Catalogue of New Roses, Hollyhocks, Gladioli, Pelargoniums, &c.*
Sutton & Sons, Reading.—*Farm Seed List for 1863.*

WORK FOR THE WEEK.

KITCHEN GARDEN.

A DISTINGUISHING feature in this department is its uniformity; straight lines and angles meet the eye in every direction, and whatever may be said in favour of a departure from this rule in the disposition of pleasure grounds, it is universally allowed that straight lines are best in the kitchen garden. Straight walks, with their edges neatly kept; seed-beds of a uniform width, with the seeds drilled in at equal distances; the disposition of plants in rows; trees all trained with the greatest exactness; together with continual surface-stirring, and the consequent absence of weeds, are amongst the distinguishing characteristics of a well-kept kitchen garden, and the most strenuous exertions should now be made for the attainment of such results. Sowing all kinds of seeds should be proceeded, with as directed in our last; the weather during the week has been so cold that little advance since then has been made. The ground, however, is in excellent order for planting and digging, which should be finished without delay, and groundwork in general completed. *Asparagus*, top-dress the beds, taking care not to injure the plants with the rake or fork. A little Celery or Lettuce seed may be sown over the beds. *Artichokes*, *Globe*, they should now be dressed, superfluous shoots removed, and fresh plantations made if required. As this is generally a permanent crop, the ground should be well prepared by deep trenching, and a plentiful application of rich manure. *Beet*, may be sown in drills a foot apart. *Broccoli*, make a sowing of Grange's Early White. *Cabbage*, plant-out autumn-sown, and weed beds left for Coleworts. *Capsicums*, sow on a hotbed. *Cauliflowers*, give attention to the plants under hand-lights by surface-stirring and giving air on all suitable occasions; tilt the glasses on the side away from the wind in cold windy weather, and remove them altogether on the first occurrence of genial showers. Do not let those in frames, or the young seedling plants that are now pricked-out, suffer from exposure to the cutting east or north-east winds, so prevalent at this season of the year. *Peas*, continue sowing for succession crops; earth-up and stick those already up as they require it. *Potatoes*, plant for the principal crop while the ground continues in good working order. *Sea-kale*, cover-up for a succession; fermenting substances may soon be dispensed with for this purpose, as it will merely require to be covered for blanching. *Spinach*, when picking over the autumn-sown, if they were left standing rather thickly together, it is as well to remove every alternate plant entirely, as it will give a greater facility for stirring the soil, and induce a larger growth in those left standing. Sow Turnips, Carrots, Leeks, Onions, Parsley, small salad, and pot herbs.

FLOWER GARDEN.

The rockery is a beautiful and pleasing addition to this department. Many, even small, places will admit of forming an imitation of rocky surfaces where they can be made to harmonise with the surrounding objects; and if the outline be simple, and the surface not too much broken, the following plants, suitable for such situations, will produce a very good effect:—the different species of *Alyssum*, *Arabis*, *Astragalus*, *Iberis*, *Draba*, *Saxifraga*, *Sedum*, the dwarf species of *Campanula*, *Dianthus*, *Veronica*, *Saponaria*, with *Phloxes* of dwarf habits. Vacancies should now be filled up in the shrubbery-borders. Plant-out *Pentstemons*, *Phloxes*, *Lysimachia*, *Delphiniums*, *Lupines*, *Sweet Williams*, *Antirrhinums*, *Clove Carnations*, *Anne Boleyn Pinks*, *Brompton Stocks*, and double *Wallflowers*. Sow a collection of half-hardy and hardy annuals on a warm border, and sow some *Sweet Peas* in pots and in the open ground.

STOVE.

Complete the shifting of all specimen plants as quickly as possible, and keep a sharp look-out for insects. Let 60° be the minimum temperature for the future, except the weather be very severe. Keep a brisk, growing, moist temperature during the day, and shut-up early.

GREENHOUSE AND CONSERVATORY.

If not already completed proceed vigorously with the shifting of plants, and if they are well rooted and in good health do not be afraid of giving them a liberal shift. See that *Ericas* and *Epacris* do not suffer for want of water. While the variable weather which usually characterises March continues, attention must be directed to the conservatory, that a uniform and moderate temperature may be preserved. The violent showers and boisterous gales, which frequently occur at this season, succeeded

by intervals of mild weather and bright sunshine, render some management necessary. Fires should be dispensed with as much as possible, and air admitted on all favourable occasions. On still nights the house may be damped and the syringe used, and as the plants exhibit vigour atmospheric moisture may be increased generally.

FORCING-PIT.

Introduce fresh plants for succession as fast as others are removed to the conservatory. Pinks which have trussed-up will be better in a mild heat, and Lily of the Valley should be removed to a lower temperature as soon as the first flowers are open. Keep a brisk growing temperature, with plenty of air and moisture in clear weather, and avoid crowding the plants as much as possible. Stop the barren shoots of *Perpetual Roses*; these rob the blossom-buds. Take care that no plants suffer for want of water.

PITS AND FRAMES.

Keep a nice growing heat in the cutting-frame; if the linings are becoming cold turn them to the bottom, and add some well-fermented dung. There will now be some empty frames to dispose of. Make up some beds of well-fermented leaves a foot longer and broader than the frames, and place these upon the beds when finished. They will be required for the reception of potted-off cuttings. Take those cuttings out of the cutting-frame that are well rooted, and place them in a cooler atmosphere to harden-off. Continue to put in cuttings of those plants previously recommended.

W. KEANE.

DOINGS OF THE LAST WEEK.

KITCHEN GARDEN.

THE change in the weather has come quite opportunely, as it will help to keep many things back that otherwise would have been injured by a slight frost. Used frosty mornings for wheeling, and during the day turned over soil intended for Parsnips, Onions, &c. Dug and trenched over empty ground. Dug ground intended for general seed-bed, so as to sow Greens, Savoyes, &c., about the end of the month. Planted out succession Cabbages, and a row or two of Red for pickling, and continued the routine much the same as last week; sticking a small handful of dry hay into the heart of the Broccoli just coming in; protecting Radishes, &c.; planting out forced Sea-kale; putting a few warm leaves over that out of doors, and some hand-lights over Rhubarb.

FRUIT GARDEN.

Proceeded with planting, root-pruning a few Plums that were making too strong wood, and looked out for protecting material for Peaches and Apricots, if the frost should prove too severe. Had, also, some large boughs of evergreens in readiness to place round forward Pears, if the frost should be more severe. Proceeded in fine days with nailing and tying. Grafting should also be proceeded with as the sap moves. In the case of Vines, all grafting should take place before the sap moves at all. If not done then, the operator should wait until the foliage is expanded, and then either cut down and graft with an unstarted scion, or bring a growing plant and inarch on a young shoot. The modes were fully detailed some time ago. The chief point in all such matters is to unite the inner bark of the stock and the scion, the modes of doing so are of less importance. This is about the best time of the year for grafting all sorts of trees to be grown in the liliputian form; and if the stocks have been previously established in pots, and these when grafted are set in a mild hot-bed, the union will be all the sooner effected. Put up beds for Melons; will in the meantime fill them with cuttings of various things. Shut up orchard-houses in these cold nights, but opened them early, not only to give abundance of air, but to keep back as much as possible, though some of the trees are in full bloom. Trees on the walls left unnailed, and hanging from the wall, will, as yet, be in no danger. At this season much of the success will consist in retarding, rather than accelerating, before the trees come into blossom. After that the more sun we can give the better it will be on ordinary occasions.

Some correspondents cannot see through this so as to use their protecting mediums to the best advantage. Our practice would depend entirely on the simple principle that the later that such trees—as Peaches, Apricots, Cherries, Plums, Pears, &c., bloomed in our variable climate, the more likely are we to have a regular crop; as many of these when they bloom early and even set well, have the fruit destroyed in the young state;

when if they had been a fortnight or three weeks later all might have been well. Suppose, then, that an amateur has a piece of sheeting over a favourite tree, as soon as the buds begin to swell freely, the sheeting should exclude the heat of the sun by day, and be removed at night so that the buds may be chilled. Of course, if the frost be so severe as to injure such buds—say 10° to 15° , then the cloth should be on night and day. With only a few degrees of frost, until the buds of the flower are sufficiently open to expose the parts of fructification, the cooler the trees are kept the better. Two advantages are thus gained—the trees will bloom later, when the weather may be supposed to be milder, and then when they do bloom the earth will be warmer, and there will be more of a reciprocal action between roots and branches. From the time that the bloom opens our tactics must change. The more light and heat in a moderate way the blossoms then receive, the better will the fruit set and swell. We say in a moderate way, for after a frosty morning, if the sun is exceedingly bright, its force against the wall would be so great, that shading for a couple of hours in the middle of the day would be highly serviceable. If the frost has been so severe at night as to touch the young fruit at all, the trees should be shaded all the next day. In ordinary circumstances, however, when there is only a little frost, or a keen east wind, the trees should be covered at night, and only uncovered in the morning when the air becomes genial and warm. The weather must, therefore, regulate the times of covering and uncovering. In a fine genial morning in March and April, after the trees were in bloom, we would uncover early and cover up late at night. In such circumstances as to bloom and a cold wet day, we would keep the cover on night and day to keep the blossom dry. In a cold east wind with but little sun, we would open a few hours in the hottest part of the day. As already stated, before the blossoms open use covering for retarding.

All fixed coverings—be they branches, or nets, &c., have the disadvantage that a degree of weakness is induced that renders the plant less able to contend with extremes. So much is this the case that some of our best gardeners, if they cannot obtain stout moveable coverings, will use none at all, as fixed coverings they contend do as much harm as good. We do not go that length, as even a fixed covering of laurel boughs or spruce branches has saved the crop of one half of a tree, whilst the fruit on the other half was lost. The best gardeners often cannot in these matters do as they like. In one place no resources are wanting. In other places it is expected that the gardener shall secure fruit without an extra farthing of outlay, just as the Israelites were expected to make bricks without the necessary materials. After having tried many schemes with more or less success, we would recommend to all amateurs a stout material, such as sheeting, to be moved easily as necessary, as the best; and next to that, as fixtures, we would designate hexagon netting and woollen netting, because they allow light and air to pass, secure a certain amount of shade, throw past the most of heavy showers, and thus, in addition to mitigating the force of the frost, enable the flowers to stand more frost from their comparative dryness. In fact, we think all modes of protection better than none, but the superiority will much depend on the care used and the consideration given.

Changed and watered *Strawberries*. Was obliged to protect *Strawberries* in pots in the open air, as within these few days they have had more frost than they would have had all the winter, so that our previous protection, without protection now, would have done more harm than good. If *Strawberry*-pots are now frozen as hard as building bricks, be sure the fruiting will be apt to suffer. If plunged in the ground the roots will suffer little injury; if standing on the surface and thus frozen, both buds and roots will be injured. We sometimes meet, in the garden of an amateur, with valuable plants standing in pots out of doors exposed to all weathers. A great point would be gained could such kind readers be made to see, that if plunged in the ground or planted out, such a plant would be more safe than in a pot above ground and not protected. The idea seems to prevail that a nice new plant, almost or entirely hardy, is better kept in a pot than plunged or planted out. Such friends altogether forget the degree of cold the roots of such a plant are exposed to in a frosty night, by radiation of heat and evaporation of moisture from the sides of an exposed pot. Had we such a good society for plants as the one for preventing cruelty to animals, we should see less of pots exposed out of doors in winter with plants in them. For such matters, and all about budding and grafting, we would wish all amateurs with a spice

of enthusiasm, to invest 3s. in the "Science and Practice of Gardening."

Finding there were still a few of the black fly in the Peach-house, fumigated leaves and fruit with capsicums and bruised laurel leaves, and then with a couple of Neal's pastils, which have made them disappear at present. It is best not to confine such operations to one material, but to vary it, and always to be sure not to use the smoke too strong. It is better to repeat the process after a day or two of interval. For a lean-to house 10 feet at back, 10 feet wide, and 50 feet in length, two pastils well smothered, and about 6 ozs. of shag tobacco, are separately enough at one time. It is quite easy to use such a dose as will destroy every living creature, but then it may be easy to destroy the plants likewise. The strongest dose of smoking will not destroy the eggs, and of these there may be thousands; and, therefore, if ever a colony is formed, there is not only the necessity of killing what is alive but of doing for others as they come into existence. Such matters are apt to make gardeners rather cruel-hearted on the vermin, though no class of men, as a whole, are more kindhearted. "Give a thorough good dose and have done with it," is by no means sound advice. I once saw a beautiful house of Peaches just nicely set, and the swelling fruit throwing their embracing blossoms off. A few green fly appeared, and it was ordered to be smoked. Next morning after a good syringing, some flies were to be found alive, and an extra dose of tobacco smoking was decided on for the next night, and some poor fellows were shut up in the nocturnal atmosphere blowing away with bellows at the tobacco retorts, until on opening the door the gardener was pretty well knocked down with the aroma that saluted him, and then there were orders for the operators to come out, which they did, almost as stupid as if they had been lolling in an opium-eater's paradise. And did they kill all insects? Yes, we believe, every one that was then alive; but there were plenty more during the season, and a sickly vegetation during the year, and what I want to note more especially is, that by the second day there was scarcely a fruit in the house; but all the little set fruit were strewed over the floor as thickly as if you had meant to sow rows of Peas. From that day to this, though forced at times to use smoking and washing moderately, we have great faith in the "Weaver remedy," of "catching them and killing them," and if the remedy is applied soon enough, people will be surprised what the fingers and thumb can accomplish.

Drew a dry hand over bunches of Grapes in bloom, especially Sweetwaters, in order to assist the setting. We observe this plan is recommended in some of our contemporaries now, though it is now many years since we first alluded to it, and found that the hand dry and applied gently along the bunch, was far better than any camel-hair brush, or anything of the kind. Some good people, however, must amuse themselves longer in seeking for a tool, than with the best of all tools, the human hand, they might do the job five times over. In some Grapes the calyx rises and covers the parts of fructification so tightly that they cannot perform their functions; but a slight rub with the dry hand, especially in a sunny day, removes the hoods and sets the pollen free to act on the pistil of the flower. By this means and a little care to give extra heat, Muscats may be set as thickly as Muscadines. Gave a little water to Figs, not too much at once, because extreme dryness and extreme moisture at once would be apt to throw off the incipient fruit. Those out of doors are still covered with laurel branches.

PLANT DEPARTMENT.

Fresh-packed some Orchids in baskets; placed some Ferns in a state of rest, as Maiden-hairs, into more heat. Fresh-potted fine-leaved Begonias, shaking most of the soil away, and repotting in similar or smaller-sized pots, using light, rich soil, packing it close, and placing the plants under the shade of Vines on a stage. Potted and put in cuttings of Coleus, and other softwooded stove plants; placed Gloxinias in heat, to start them before shifting them; put tubers of Achimenes and Gesneras into pans to start them before separating and grouping them in pots for blooming. The Achimenes may be set rather thickly in pans and boxes, covered with half an inch of sandy soil, and when 2 inches in height selected for potting and vasing. They start best under shade, as then the sun will not injure the young foliage. When such things are started in a hotbed, not only should the bed be sweet, but there should be a little air left on at top all the night, as well as during the day; for condensed moisture or steam from such beds is apt to scald the foliage,

and rarely does it recover its beauty again. In such a place the young leaves should be quite dry before the sun strikes them.

Melons in pots should not have less than from 65° to 70° average night temperature, and Pine plants for autumn fruiting should now receive their last shift, and care should be taken whilst the bed is preparing for them, that the plants are not chilled. We have seen plants throw up pigmy fruit prematurely, or a lot of suckers instead of a fruit-stem, from such checks being given to the roots, merely by allowing the plants to stand about in the cold; and because the plants do not show the effects of such treatment as readily as a Cucumber, or an early Balsam, we are too apt to imagine that they may be treated roughly with impunity. It is from thoroughly understanding this hot-and-cold affair that many things look so nice in small places. The gardener there, doing the most particular matters with his own hands, will take care that his plants receive no check. No sooner is a plant out and shifted, than it is back again in its comfortable home; but in large places you may often find numbers of plants in a cold shed at dinner time. The young people cannot be made to feel how grievously they injure their plants, in thus bringing them to a temperature of from 35° to 40°, when taking them out of and back again to one of 70°. When this is long continued, all the coaxing and warm-watering afterwards will not compensate for the serious check thus given.

Reported Fuchsias that had been pruned and started, shaking away a good portion of the old soil, and filled up with fresh rich loam. Placed Dahlias and Cannas on the floor of a house to start them, bringing both from sheds where they had stood the winter. The weather being so cold, delayed planting out bedding plants under temporary protection; but filled every little available space with cuttings of Verbenas, double Feverfew, Geraniums, &c. Made preparations for sowing lots of flower-seeds, and rolled the lawns and pruned the Roses in flower gardens; also put in Rose cuttings.—R. F.

TO CORRESPONDENTS.

HACKBERRY TREE (W. D.).—The following extract from Hogg's "Vegetable Kingdom" gives the information you ask for:—*Cerasus padus*, the Bird-cherry or Hag-berry, is common in most parts of Britain. The fruit is naceous, but infused in gin or whiskey greatly improves them, and is only surpassed by an infusion of Peach leaves." We may add that *Hag*, or *Hæg*, is the Anglo-Saxon for the Hawthorn, and the fruit of the Bird Cherry is not unlike the Haw.

VEGETABLE AND GOURD SNOW (J. Choyce).—We believe that the Royal Horticultural Society do not intend to have a show of this description like that they held last October.

CALANTHE VESTITA (Orchidophilus).—Be assured that no discount was intended. We only remember that we considered the notes of Mr. Appleby at page 90 gave the information you needed. If it does not, send your questions again to us.

GALVANISED IRON WIRE FOR TRAINING (J. McClellan).—The galvanised wire will do very well. The shoots must be tied loosely.

ACHIMENES DYING (Idem).—The Achimenes in theinery might not be ripened enough. The roots, however, whether in-doors or in houses, should rarely be in a temperature lower than 45°. A little frost injures even well-ripened buds of Achimenes.

GLASS FOR A SMALL LEAN-TO GREENHOUSE (J. P.).—If the roof is to be fixed, and the place at all exposed, it would be desirable to have British plate, seconds or thirds, 21 ozs. to the foot, and the squares 12 inches deep and 15 inches across. If the place is protected, squares 12 by 20 would do, and 16 or 15-oz. glass would be nearly a third cheaper. If sashes are to be made, then we would propose glass 10 inches wide, and 18 inches long.

LIFTING VINE ROOTS (An Old Subscriber).—As you have taken up the Vines now, place over the border a foot or 18 inches depth of warm fermenting stable manure, so as to raise the temperature of the border, 4 inches below the surface, to 75° to 80°. Keep the Vines in the house as cool as possible until they break naturally. By that time there will be roots making to sustain them.

NERIUM FLOWERS FAILING (Idem).—Place your Neriums in a sunny place out of doors after June. Water plentifully until September. Thin-out head if too thick. Do not shorten any of the shoots you leave. Give all the sun possible in the autumn, and no more water than will keep from flagging. Pot in rather stiff loam. Take them into the house in October.

PLANTING A FLOWER GARDEN (P. M.).—Were we to plant flower gardens on paper, we should require several first-rate flower-gardeners almost constantly employed. We are not able to do that. We will gladly give hints on proposed planting. Your arrangement of last year was not only simple, but very good. It is desirable to change the beds, and if you send us your own re-arrangement, we will refer to the plan and tell you our opinion.

RHODODENDRONS NOT FLOWERING (Ada).—We can only suppose that your plants were starved last season if they made no new wood. Of course, if they did not do that they could make no flower-buds. Examine the roots. See that the ball is moist to the centre. If the pot is full of roots, repot into two parts peat or heath soil, and one part of loam, with sand and charcoal. Keep in the conservatory until June. Syringe and keep close to encourage growth; then set in a shady place out of doors, and by August place pretty full in the sun, mulch with rotten old cowdung, and give plenty of water. The sorts you name will do pretty well out of doors in a sheltered place.

SOWING CLIANthus DAMPIERI SEED (An Original Subscriber).—Soak the seeds in water at 140° for some hours before sowing; then place the pot in a mild bottom heat, and cover but slightly. We would advise you to take out those you have sown, sow afresh, and treat thus—nay, further, we would put a single seed in a small pot, and take to a cooler place as soon as the plant is up. You may then transfer the plant before the pot is full of roots to a larger pot. If you had a pot of seedlings they would suffer in shifting, as the plant is touchy in enduring moving.

PELAGONIUM CULTURE (L. F. F.).—Water must be given to all plants just as they need it. In a sunny week they will want water, probably, every day, or every other day, according to circumstances. In dull weather water may be needed once a week, or once a fortnight. Your Geraniums you must treat according as you want flowers from them this season, or fine specimens in the following year. In the first case place the plants where you can command the fire heat. When they have got over the journey repot into larger pots—say 6 inches. Stop the shoots that are too strong a fortnight afterwards, and then these will flower in the end of summer. If fine plants are your object, stop all the shoots, pot in a fortnight, begin to train, and pot once or twice during the summer, but not after August or September. These will make nice early plants next summer. Let the temperature be from 45° to 50° at night in average weather, from 50° to 60° in dull days, and 10° more from sunshine. Buy "Window-Gardening for the Many," you can have it free by post for 10d. from our office.

FLUE-HEATING A GREENHOUSE (Wisbech).—Of course you lose a little heat from the top and only one side of the flue being exposed; but the top alone being exposed ought to be sufficient for such a small house if the flue is 9 or 12 inches across. We presume that the flue is almost a dead level in the house, but it would have acted better if it had risen a little from the place where it is connected with the furnace right on to the chimney. If the flue is quite level the chimney will require to be higher. There is one thing you omit—the furnace, and it strikes us as very likely that your furnace-bars are not low enough. If not many inches below the bottom of the flue, sink the bars low enough to be 24 to 30 inches below the level of the bottom of the flue. Our opinion coincides with that of our coadjutor Mr. Robson, that for all such single small houses a flue is preferable in every way to a boiler. The expense of heating such a place with a boiler alone will be much more than with a flue, as so much heat will be lost up the chimney by the first mode. And then, as for economy, you will have a small boiler, the heat will be more irregular without considerable attention, as when the fire is out the heat is soon gone; whereas, when a flue is heated it keeps its heat a long time. We would, therefore, advise the flue so far as effectiveness and economy are concerned; and we do not see why it should not draw. We should be glad to know if the hint above is of any use, and if not you may give us more particulars.—R. F.

FLOWER-GARDEN PLAN (W. B.).—We never undertake to plant. All that we can do is to criticise the planning proposed.

RHODODENDRON AUCKLANDII, &c. (W. Brown).—Sir W. Hooker ("Botanical Magazine," t. 5065), speaks of it as "magnificent," and "in some respects the finest of its genus." It flowered in this country for the first time, we believe, at Mr. Gaines' Nursery, Wandsworth, in the May of 1858. We know of no reason why it should not interbreed with *Rhododendron cilicium*.

MONOCHÆTUM (Idem).—This name is derived from two Greek words, *monos*, one, and *chaite*, a bristle; the connective of the anther being lengthened into a kind of bristle.

NAMES OF PLANTS (F. J.).—We cannot name plants from leaves alone, except in rare instances. 1 is an Echites; 3 appears to be *Cytisus filipes*. (*W. H. M.*).—*Chorozema cordatum*, (*Novice, Gorey*).—1, *Pleopeltis lycopodioides*; 2, *Phlebodium acroleptum*; 3, *Cyrtomium falcatum*; 4, *Pteris hastata*. (*An Amateur, Co. Tyrone*).—*Cyclamen com* is all right. *Polygala Dalmaniana* is a British-raised hybrid, requiring the protection of a window or a greenhouse in winter. You may prune it back when done flowering. The small shoots will strike in peat and sand, with a bell-glass or a hand-light over them. If you allowed a little seed to ripen, and sowed it in a pot in the window, that would be the easiest plan of obtaining plants. The plant will be safe enough out of doors from June to the middle of October. You are all right about the Auriculas.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

ECCENTRICITIES OF THE WORCESTER AND BATH AND WEST OF ENGLAND

POULTRY SHOWS.

I RECOLLECT hearing a story once of a lady ringing for her servant to sweep the floor after some of her visitors had departed, declaring that these same visitors had dropped so many H's, that the carpet must be strewn with them. Taking up the Worcester schedule makes me fancy that some kind friend with the dust-pan is needed, to raise up some of the classes which have dropped unheeded by the tender mercies of the Committee.

We are supposed to be living in the year 1863, when shows are no longer in their infancy, and when exhibitors expect, and have a right to expect, a different prize list. I am one of those who think it rather questionable whether the entries, being similar in amount, it is altogether justice to the exhibitor to have prizes varying in amount. If you take any catalogue and make a proportion sum—if Dorking entries receive such an amount in prizes, Malay entries should receive so much; or take any other breeds. I do not think that it always holds that those classes for which, if I may so call it, extra prizes have been offered fill in proportion to those prizes, whilst often it is palpably the opposite. Take Devizes, where, as some of your readers may recollect, I took down a few notes. There £5 5s. offered

to Spanish and coloured Dorkings produced respectively ten and fifteen entries; whilst £2 offered to Polands (any variety), produced six, and the like amount offered to Brahmas produced six. Some of the Bantams and Buenos Ayrean Ducks far outstripped this number; yet each had paid an entrance fee of 6s., and the Dorkings and Spanish paid no more. At the same Show sixteen pens of Cochins had £9 divided between them; yet these only paid the same entrance fee.

But to return to the schedule of the Worcester Show. Where are the classes for White Dorkings, Malays, and Brahmas? All of these breeds expect classes at "grand" shows. Why are White-crested Black Polish chickens to have prizes, while the aged specimens may take refuge in the Any other variety class? In my simplicity I believed that Polish adults were handsomer than chickens. Why are Black East-Indian Ducks classless? Wherefore are spangled Hamburgs cut off from a third prize in each class, whilst their brothers and sisters, the Pencilled, have three? At the Crystal Palace Pencilled produced, omitting single cocks, thirty-nine pens, but Spangled forty-four.

In exchange for these sins of omission, we have Worcester setting us the bright example of separate classes for Crève Cœurs. These birds, which one of your correspondents lately denominated degenerate Poles, have yet to prove their merits. I cannot say I was over-pleased with the specimen I once kept, but this may have been an exception. But surely these birds should not displace other well-known and useful breeds from the class list.

I fancy, too, that some exhibitors will ask where their birds are to be kept for one whole week. Every place for exhibitions of poultry is not the Crystal Palace, and in hot July too! Two days are sufficiently long for any show except the really "grand" ones—Birmingham and the Crystal Palace. The Committee should recollect that the poultry are not cattle, and that they cannot stand the confinement in the same way.

I have written you at once, as there is plenty of time for the Committee to alter some of their plans. If they do not, I fear their Show will not prove so successful as they doubtless imagine.

Turning to the schedule of the Bath and West of England Poultry Show, I find no classes for Gold or Silver Polands, none for Brahmas; Gold and Silver-spangled Hamburgs massed together, while their Pencilled brethren enjoy their two classes.

To deduct 3s. 6d. from each entry in the sweepstakes for single cocks seems monstrous. Surely there must be some error here.

Last, not least, it is a five-days Show, the birds being cooped about seventy hours before the Show commences. Altogether, many valuable birds—if their owners are simple enough to send them—will be cooped-up for ten days or more, journey included!

Will one of the latter rules prove a "soothing syrup" to them? It runs—"In case of the death of any poultry during the time of exhibition, the bird or birds" (very cool) "so lost will be sent back for the inspection of the exhibitor." Great satisfaction may it give him, especially if the death is from a contagious disease, and the dead and living birds journey home together!—Y. B. A. Z.
